$$\mathbf{I}_Y = \frac{\mathbf{V}_Y}{\mathbf{Z}} = \frac{133 \angle 120^\circ}{10 \angle 53^\circ 8'} = 13.3 \angle 66^\circ 52'$$

It lags behind the reference vector *i.e.*  $V_R$  by  $173^\circ 8'$  which amounts to lagging behind its phase voltage  $V_Y$  by  $53^\circ 8'$ .

$$\mathbf{I}_B = \frac{\mathbf{V}_B}{\mathbf{Z}} = \frac{133 \angle 240^\circ}{10 \angle 53^\circ 8'} = 13.3 \angle 173^\circ 8'$$

This current leads  $V_R$  by  $66^\circ 52'$  which is the same thing as *lagging* behind its phase voltage by  $53^\circ 8'$ . For calculation of power, consider R-phase

$$\mathbf{V}_R = (133 - j0); \mathbf{I}_R = 13.3(0.6 - j0.8) = (7.98 - j10.64)$$

Using method of conjugates, we get

$$\mathbf{P}_{VA} = (133 - j0)(7.98 - j10.64) = 1067 - j1415$$

$\therefore$  Real power absorbed/phase = 1067 W – as before

**Example 19.5.** When the three identical star-connected coils are supplied with 440 V, 50 Hz, 3- $\phi$  supply, the 1- $\phi$  wattmeter whose current coil is connected in line R and pressure coil across the phase R and neutral reads 6 kW and the ammeter connected in R-phase reads 30 Amp. Assuming RYB phase sequence find:

- (i) resistance and reactance of the coil, (ii) the power factor, of the load  
(iii) reactive power of 3- $\phi$  load.

(Elect. Engg.-I, Nagpur Univ. 1993)

**Solution.**  $V_{ph} = 440 / \sqrt{3} = 254 \text{ V}; I_{ph} = 30 \text{ A}$   
(Fig. 19.17.)

Now,  $V_{ph} I_{ph} \cos \phi = 6000$ ;  $254 \times 30 \times \cos \phi = 6000$

$\therefore \cos \phi = 0.787$ ;  $\phi = 38.06^\circ$  and  $\sin \phi = 0.616$ ;  $Z_{ph} = V_{ph} / I_{ph} = 254/30 = 8.47 \Omega$

(i) Coil resistance  $R = Z_{ph} \cos \phi = 8.47 \times 0.787 = 6.66 \Omega$

$X_L = Z_{ph} \sin \phi = 8.47 \times 0.616 = 5.22 \Omega$

(ii) p.f. =  $\cos \phi = 0.787$  (lag)

(iii) Reactive power =  $\sqrt{3} V_L I_L \sin \phi = \sqrt{3} \times 440 \times 30 \times 0.616 = 14,083 \text{ VA}$  **14.083 kVA**

**Example 19.6** Calculate the active and reactive components in each phase of Y-connected 10,000 V, 3-phase alternator supplying 5,000 kW at 0.8 p.f. If the total current remains the same when the load p.f. is raised to 0.9, find the new output.

(Elements of Elect. Engg.-I, Bangalore Univ.)

**Solution.**  $5000 \times 10^3 = \sqrt{3} \times 10,000 \times I_L \times 0.8$ ;  $I_L = 361 \text{ A}$

active component =  $I_L \cos \phi = 361 \times 0.8 = 288.8 \text{ A}$

reactive component =  $I_L \sin \phi = 361 \times 0.6 = 216.6 \text{ A}$

New power  $P = \sqrt{3} V_L I_L \cos \phi = \sqrt{3} \times 10^4 \times 361 \times 0.9 = 5,625 \text{ kW}$

[or new power =  $5000 \times 0.9/0.8 = 5625 \text{ kW}$ ]

**Example 19.7.** Deduce the relationship between the phase and line voltages of a three-phase star-connected alternator. If the phase voltage of a 3-phase star-connected alternator be 200 V, what will be the line voltages (a) when the phases are correctly connected and (b) when the connections to one of the phases are reversed.

**Solution.** (a) When phases are correctly connected, the vector diagram is as shown in Fig. 19.12. (b). As proved in Art. 19.7

Fig. 19.18

$$V_{RY} = V_{YB} = V_{BR} = \sqrt{3} E_{ph}$$

$$\text{Each line voltage} = \sqrt{3} \times 200 = 346 \text{ V}$$

(b) Suppose connections to B-phase have been reversed. Then voltage vector diagram for such a case is shown in Fig. 19.18. It should be noted that  $E_B$  has been drawn in the reversed direction, so that angles between the three-phase voltages are  $60^\circ$  (instead of the usual  $120^\circ$ )

$$V_{RY} = E_R - E_Y \quad \dots \text{vector difference}$$

$$= 2 \times E_{ph} \times \cos 30^\circ = \sqrt{3} \times 200 = 346 \text{ V}$$

$$V_{YB} = E_Y - E_B \quad \dots \text{vector difference}$$

$$= 2 \times E_{ph} \times \cos 60^\circ = 2 \times 200 \times \frac{1}{2} = 200V$$

$$V_{BR} = E_B - E_R \dots \text{vector difference} = 2 \times E_{ph} \times \cos 60^\circ = 2 \times 200 \times \frac{1}{2} = 200V$$

**Example 19.8** In a 4-wire, 3-phase system, two phases have currents of 10A and 6A at lagging power factors of 0.8 and 0.6 respectively while the third phase is open-circuited. Calculate the current in the neutral and sketch the vector diagram.

**Solution.** The circuit is shown in Fig. 19.19 (a).

$$\phi_1 = \cos^{-1}(0.8) = 36^\circ 54'; \phi_2 = \cos^{-1}(0.6) = 53^\circ 6'$$

Let  $V_R$  be taken as the reference vector. Then

$$\mathbf{I}_R = 10 \angle -36^\circ 54' = (8 - j6) \quad \mathbf{I}_Y = 6 \angle -173^\circ 6' = (-6 - j0.72)$$

The neutral current  $\mathbf{I}_N$  as shown in Fig. 19.16 (b), is the sum of these two currents.

$$\therefore \mathbf{I}_N = (8 - j6) + (-6 - j0.72) = 2 - j6.72 = 7 \angle -73^\circ 26'$$

Fig. 19.19

**Example 19.9 (a).** Three equal star-connected inductors take 8 kW at power factor 0.8 when connected a 460-V, 3-phase, 3-wire supply. Find the line currents if one inductor is short-circuited.

**Solution.** Since the circuit is balanced, the three line voltages are represented by

$$V_{ab} = 460 \angle 0^\circ; V_{bc} = 460 \angle -120^\circ \text{ and } V_{ca} = 460 \angle 120^\circ$$

The phase impedance can be found from the given data :

$$8000 = \sqrt{3} \times 460 \times I_L \times 0.8 \therefore I_L = I_{ph} = 12.55 \text{ A}$$

$$Z_{ph} = V_{ph} / I_{ph} = 460 / \sqrt{3} \times 12.55 = 21.2 \Omega;$$

$$\therefore Z_{ph} = 21.2 \angle 36.9^\circ \text{ because } \phi = \cos^{-1}(0.8) = 36.9^\circ$$

As shown in the Fig. 19.20, the phase  $c$  has been short-circuited. The line current  $I_a = V_{ac}/Z_{ph} = -V_{ca}/Z_{ph}$  because the current enters at point  $a$  and leaves from point  $c$ .

$$\therefore I_a = -460 \angle 120^\circ / 21.2 \angle 36.9^\circ = 21.7 \angle 83.1^\circ$$

Similarly,  $I_b = V_{bc}/Z_{ph} = 460 \angle 120^\circ / 21.2 \angle 36.9^\circ = 21.7 \angle -156.9^\circ$ . The current  $I_c$  can be found by applying KVL to the neutral point N.

$$\therefore I_a + I_b + I_c = 0 \quad \text{or} \quad I_c = -I_a - I_b$$

Fig. 19.20

$$\therefore I_C = 21.7 \angle 83.1^\circ - 21.7 \angle -156.9^\circ = 37.3 \angle 53.6^\circ$$

Hence, the magnitudes of the three currents are : 21.7 A;  
21.7 A; 37.3 A.

**Example 19.9 (b).** Each phase of a star-connected load consists of a non-reactive resistance of  $100 \Omega$  in parallel with a capacitance of  $31.8 \mu F$ .

Calculate the line current, the power absorbed, the total kVA and the power factor when connected to a 416-V, 3-phase, 50-Hz supply.

**Solution.** The circuit is shown in Fig. 14.20.

$$V_{ph} = (416 / \sqrt{3}) \angle 0^\circ = 240 \angle 0^\circ = (240 + j0)$$

Admittance of each phase is

$$\begin{aligned} Y_{ph} &= \frac{1}{R} + jC = \frac{1}{100} + j314 \times 31.8 \times 10^{-6} \\ &= 0.01 + j0.01 \end{aligned}$$

$$\begin{aligned} \therefore I_{ph} &= V_{ph} \cdot Y_{ph} = 240(0.01 + j0.01) \\ &= 2.4 + j2.4 = 3.39 \angle 45^\circ \end{aligned}$$

Since  $I_{ph} = I_L$  - for a star connection  $\therefore I_L = 3.39 \text{ A}$

Power factor =  $\cos 45^\circ = 0.707$  (leading)

Now  $V_{ph} = (240 + j0)$ ;  $I_{ph} = 2.4 + j2.4$

$$\therefore P_{VA} = (240 + j0)(2.4 + j2.4)$$

$$= 240 \times 2.4 - j2.4 \times 240 = 576 - j576 = 814.4 \angle -45^\circ \quad \dots \text{ per phase}$$

Hence, total power =  $3 \times 576 = 1728 \text{ W} = 1.728 \text{ kW}$

Total voltamperes =  $814.4 \times 3 = 2,443 \text{ VA}$ ; kilovolt amperes = **2.433 kVA**

**Example 19.10.** A three phase 400-V, 50 Hz, a.c. supply is feeding a three phase delta-connected load with each phase having a resistance of 25 ohms, an inductance of 0.15 H, and a capacitor of 120 microfarads in series. Determine the line current, volt-amp, active power and reactive volt-amp. [Nagpur University, November 1999]

**Solution.** Impedance per phase  $r + jX_L - jX_C$

$$X_L = 2\pi \times 50 \times 0.15 = 47.1 \Omega$$

$$X_C = \frac{10^6}{32.37} = 26.54 \Omega$$

$\cos \phi = \frac{25}{32.37}$  Lagging, since inductive reactance is dominating.

$$\text{Phase Current} = \frac{400}{25 + j20.56} = 12.357$$

$$\text{Line Current} = \sqrt{3} \times 12.357 = 21.4 \text{ amp}$$

Since the power factor is 0.772 lagging,

Fig. 19.21

Fig. 19.22

$$P = \text{total three phase power} = \sqrt{3} V_L I_L \cos \phi \times 10^{-3} \text{ kW}$$

$$= \sqrt{3} \times 400 \times 21.4 \times 0.772 \times 10^{-3} = 11.446 \text{ kW}$$

$$S = \text{total 3 ph kVA} = \frac{11.446}{0.772} = 14.83 \text{ kVA}$$

$$Q = \text{total 3 ph "reactive kilo-volt-amp"} = \sqrt{3} (S^2 - P^2)^{0.50} = 9.43 \text{ kVAR lagging}$$

**Example 19.11.** Three phase star-connected load when supplied from a 400 V, 50 Hz source takes a line current of 10 A at 66.86° w.r. to its line voltage. Calculate : (i) Impedance-Parameters, (ii) P.f. and active-power consumed. Draw the phasor diagram.

[Nagpur University, April 1998]

**Solution.** Draw three phasors for phase-voltages.

Fig. 19.23

These are  $V_{ph1}$ ,  $V_{ph2}$ ,  $V_{ph3}$  in Fig 19.23. As far as phase number 1 is concerned, its current is  $I_1$  and the associated line voltage is  $V_{L1}$ .  $V_{L1}$  and  $V_{ph1}$  differ in phase by  $30^\circ$ . A current differing in phase with respect to line voltage by  $66.86^\circ$  and associated with  $V_{ph1}$  can only be lagging, as shown in Fig. 19.23. This means  $\phi = 36.86^\circ$ , and the corresponding load power factor is 0.80 lagging.

$$Z = V_{ph}/I_{ph} = 231/10 = 23.1 \text{ ohms}$$

$$R = Z \cos \phi = 23.1 \times 0.8 = 18.48 \text{ ohms}$$

$$X_L = Z \sin \phi = 23.1 \times 0.6 = 13.86 \text{ ohms}$$

$$\text{Total active power consumed} = 3 V_{ph} I_{ph} \cos \phi$$

$$= 3 \times 231 \times 10 \times 0.8 \times 10^{-3} \text{ kW} = 5.544 \text{ kW}$$

$$\text{or total active power} = 3 \times I^2 R = 3 \times 10^2 \times 18.48 = 5544 \text{ watts}$$

For complete phasor diagram for three phases, the part of the diagram for Phase 1 in Fig 19.23 has to be suitably repeated for phase-numbers 2 and 3.

### 19.9. Delta ( $\Delta$ )\* or Mesh Connection

In this form, of interconnection the *dissimilar* ends of the three phase winding are joined together i.e. the 'starting' end of one phase is joined to the 'finishing' end of the other phase and

Fig. 19.24

so on as showing in Fig. 19.24 (a). In other words, the three windings are joined in series to form a closed mesh as shown in Fig. 19.24 (b).

Three leads are taken out from the three junctions as shown as outward directions are taken as positive.

It might look as if this sort of interconnection results in

\* As an aid to memory, remember that first letter *D* of Dissimilar is the same as that of Delta.

shortcircuiting the three windings. However, if the system is balanced then sum of the three voltages round the closed mesh is zero, hence no current of fundamental frequency can flow around the mesh when the terminals are open. It should be clearly understood that at any instant, the e.m.f. in one phase is equal and opposite to the resultant of those in the other two phases.

This type of connection is also referred to as 3-phase, 3-wire system.

### (i) Line Voltages and Phase Voltages

It is seen from Fig. 19.24 (b) that there is only one phase winding completely included between any pair of terminals. Hence, in  $\Delta$ -connection, the voltage between any pair of lines is equal to the phase voltage of the phase winding connected between the two lines considered. Since phase sequence is  $R Y B$ , the voltage having its positive direction from  $R$  to  $Y$  leads by  $120^\circ$  on that having its positive direction from  $Y$  to  $B$ . Calling the voltage between lines 1 and 2 as  $V_{RY}$  and that between lines 2 and 3 as  $V_{YB}$ , we find that  $V_{RY}$  lead  $V_{YB}$  by  $120^\circ$ . Similarly,  $V_{YB}$  leads  $V_{BR}$  by  $120^\circ$  as shown in Fig. 19.23. Let  $V_{RY} = V_{YB} = V_{BR} =$  line voltage  $V_L$ . Then, it is seen that  $V_L = V_{ph}$ .

### (ii) Line Currents and Phase Currents

It will be seen from Fig. 19.24 (b) that current in each line is the **vector difference** of the two phase currents flowing through that line. For example

$$\begin{aligned} \text{Current in line 1 is } I_1 &= I_R - I_B \\ \text{Current in line 2 is } I_2 &= I_Y - I_R \quad \text{vector difference} \\ \text{Current in line 3 is } I_3 &= I_B - I_Y \end{aligned}$$

Current in line No. 1 is found by compounding  $I_R$  and  $I_B$  reversed and its value is given by the diagonal of the parallelogram of Fig. 19.25. The angle between  $I_R$  and  $I_B$  reversed (*i.e.*  $-I_B$ ) is  $60^\circ$ . If  $I_R = I_Y =$  phase current  $I_{ph}$  (say), then

Current in line No. 1 is

$$I_1 = 2 \times I_{ph} \times \cos(60^\circ/2) = 2 \times I_{ph} \sqrt{3}/2 = \sqrt{3} I_{ph}$$

Current in line No. 2 is

$$I_2 = I_B - I_Y \dots \text{vector difference} = \sqrt{3} I_{ph} \text{ and current}$$

in line No. 3 is  $I_3 = I_B - I_Y \therefore$  Vector difference  $= \sqrt{3} \cdot I_{ph}$

Since all the line currents are equal in magnitude *i.e.*

$$I_1 = I_2 = I_3 = I_L$$

$$\therefore I_L = \sqrt{3} I_{ph}$$

With reference to Fig. 19.25, it should be noted that

1. line currents are  $120^\circ$  apart ;
2. line currents are  $30^\circ$  behind the respective phase currents ;
3. the angle between the line currents and the corresponding line voltages is  $(30 + \phi)$  with the current lagging.

### (iii) Power

Power/phase  $= V_{ph} I_{ph} \cos \phi$  ; Total power  $= 3 \times V_{ph} I_{ph} \cos \phi$ . However,  $V_{ph} = V_L$  and  $I_{ph} = I_L / \sqrt{3}$   
Hence, in terms of line values, the above expression for power becomes

$$P = 3 \times V_L \times \frac{I_L}{\sqrt{3}} \times \cos \phi = \sqrt{3} V_L I_L \cos \phi$$

where  $\phi$  is the phase power factor angle.

Fig. 19.25

**19.10. Balanced Y/Δ and Δ/Y Conversion**

In view of the above relationship between line and phase currents and voltages, any balanced Y-connected system may be completely replaced by an equivalent Δ-connected system. For example, a 3-phase, Y-connected system having the voltage of  $V_L$  and line current  $I_L$  may be replaced by a Δ-connected system in which phase voltage is  $V_L$  and phase current is  $I_L / \sqrt{3}$ .

Fig. 19.26

Similarly, a balanced Y-connected load having equal branch impedances each of  $Z \angle \phi$  may be replaced by an equivalent Δ-connected load whose each phase impedance is  $3Z \angle \phi$ . This equivalence is shown in Fig. 19.26.

For a balanced star-connected load, let

$V_L$  = line voltage;  $I_L$  = line current ;  $Z_Y$  = impedance/phase

$$\therefore V_{ph} = V_L / \sqrt{3}; I_{ph} = I_L; Z_Y = V_L / (\sqrt{3} I_L)$$

Now, in the equivalent Δ-connected system, the line voltages and currents must have the same values as in the Y-connected system, hence we must have

$$V_{ph} = V_L, I_{ph} = I_L / \sqrt{3} \therefore Z_{\Delta} = V_L / (I_L / \sqrt{3}) = \sqrt{3} V_L / I_L = 3Z_Y$$

$$\therefore Z_{\Delta} \angle \phi = 3Z_Y \angle \phi \quad (V_L / I_L = \sqrt{3} Z_Y)$$

or  $Z_{\Delta} = 3Z_Y$  or  $Z_Y = Z_{\Delta} / 3$

The case of unbalanced load conversion is considered later. (Art. 19.34)

**Example 19.12.** A star-connected alternator supplies a delta connected load. The impedance of the load branch is  $(8 + j6)$  ohm/phase. The line voltage is 230 V. Determine (a) current in the load branch, (b) power consumed by the load, (c) power factor of load, (d) reactive power of the load. (Elect. Engg. A.M.Ae. S.I. June 1991)

**Solution.** Considering the Δ-connected load, we have  $Z_{ph} = \sqrt{8^2 + 6^2} = 10 \Omega$ ;  $V_{ph} = V_L = 230 \text{ V}$

(a)  $I_{ph} = V_{ph} / Z_{ph} = 230 / 10 = 23 \text{ A}$

(b)  $I_L = \sqrt{3} I_{ph} = \sqrt{3} \times 23 = 39.8 \text{ A}$ ;  $P = \sqrt{3} V_L I_L \cos \phi = \sqrt{3} \times 230 \times 39.8 \times 0.8 = 12,684 \text{ W}$

(c) p.f.  $\cos \phi = R / Z = 8 / 10 = 0.8$  (lag)

(d) Reactive power  $Q = \sqrt{3} V_L I_L \sin \phi = \sqrt{3} \times 230 \times 39.8 \times 0.6 = 9513 \text{ W}$

**Example 19.13.** A 220-V, 3-φ voltage is applied to a balanced delta-connected 3-φ load of phase impedance  $(15 + j20) \Omega$

(a) Find the phasor current in each line. (b) What is the power consumed per phase ?

(c) What is the phasor sum of the three line currents ? Why does it have this value ?

(Elect. Circuits and Instruments, B.H.U.)

**Solution.** The circuit is shown in Fig. 19.27 (a).

$$V_{ph} = V_L = 220 \text{ V}; Z_{ph} = \sqrt{15^2 + 20^2} = 25 \Omega, I_{ph} = V_{ph} / Z_{ph} = 220 / 25 = 8.8 \text{ A}$$

$$(a) I_L = \sqrt{3} I_{ph} = \sqrt{3} \times 8.8 = \mathbf{15.24 \text{ A}} \quad (b) P = I_{ph}^2 R_{ph} = 8.8^2 \times 15 = \mathbf{462 \text{ W}}$$

(c) Phasor sum would be zero because the three currents are equal in magnitude and have a mutual phase difference of  $120^\circ$ .

**Solution by Symbolic Notation**

Taking  $V_{RY}$  as the reference vector, we have [Fig. 19.27 (b)]

Fig. 19.27

$$\mathbf{V}_{RY} \quad 220 \quad 0^\circ;$$

$$\mathbf{V}_{YB} \quad 220 \quad 120^\circ$$

$$\mathbf{V}_{BR} \quad 220 \quad 120^\circ;$$

$$\mathbf{Z} \quad 15 \quad j20 \quad 125 \quad 53^\circ 8'$$

$$\mathbf{I}_R = \frac{\mathbf{V}_{RY}}{\mathbf{Z}} = \frac{220 \quad 0^\circ}{25 \quad 53^\circ 8'} = 8.8 \quad 53^\circ 8' \quad (5.28 \quad j7.04) \text{ A}$$

$$\mathbf{I}_Y = \frac{\mathbf{V}_{YB}}{\mathbf{Z}} = \frac{220 \quad 120^\circ}{25 \quad 53^\circ 8'} = 8.8 \quad 173^\circ 8' \quad (-8.75 \quad j1.05) \text{ A}$$

$$\mathbf{I}_B = \frac{\mathbf{V}_{BR}}{\mathbf{Z}} = \frac{220 \quad 120^\circ}{25 \quad 53^\circ 8'} = 8.8 \quad 66^\circ 55' \quad (3.56 \quad j8.1)$$

(a) Current in line No. 1 is

$$\mathbf{I}_1 = \mathbf{I}_R - \mathbf{I}_B = (5.28 - j7.04) - (4.56 + j8.1) = (1.72 - j15.14) = 15.23 \angle -83.5^\circ$$

$$\mathbf{I}_2 = \mathbf{I}_Y - \mathbf{I}_R = (-8.75 - j1.05) - (5.28 - j7.04) = (-14.03 + j6.0) = 15.47 \angle -156.8^\circ$$

$$\mathbf{I}_3 = \mathbf{I}_B - \mathbf{I}_Y = (3.56 - j8.1) - (-8.75 - j1.05) = (12.31 + j9.15) = 15.26 \angle 36.8^\circ$$

(b) Using conjugate of voltage, we get for R-phase

$$\mathbf{P}_{VA} = \mathbf{V}_{RY} \cdot \mathbf{I}_R = (220 - j0) (5.28 - j7.04) = (1162 - j1550) \text{ voltampere}$$

Real power per phase = **1162 W**

(c) Phasor sum of three line currents

$$= \mathbf{I}_1 + \mathbf{I}_2 + \mathbf{I}_3 = (1.72 - j15.14) + (-14.03 + j6.0) + (12.31 + j9.15) = 0$$

As expected, phasor sum of 3 line currents drawn by a balanced load is zero because these are equal in magnitude and have a phase difference of  $120^\circ$  amongst themselves.

**Example 19.14** A 3- $\phi$ ,  $\Delta$ -connected alternator drives a balanced 3- $\phi$  load whose each phase current is 10 A in magnitude. At the time when  $I_a = 10 \angle 30^\circ$ , determine the following, for a phase sequence of abc.

(i) Polar expression for  $I_b$  and  $I_c$  and (ii) polar expressions for the three line current. Show the phase and line currents on a phasor diagram.

**Solution. (i)** Since it is a balanced 3-phase system,  $I_b$  lags  $I_a$  by  $120^\circ$  and  $I_c$  lags  $I_a$  by  $240^\circ$  or leads it by  $120^\circ$ .

$$\therefore I_b = I_a \angle -120^\circ = 10 \angle (30^\circ - 120^\circ) = 10 \angle -90^\circ$$

$$I_c = I_a \angle 120^\circ = 10 \angle (30^\circ + 120^\circ) = 10 \angle 150^\circ$$

The 3-phase currents have been represented on the phasor diagram of Fig. 19.28 (b).

As seen from Fig. 19.28 (b), the line currents lag behind their nearest phase currents by  $30^\circ$ .

Fig. 19.28

$$\begin{aligned} \therefore I_{L1} &= \sqrt{3} I_a \quad (30^\circ \ 30^\circ) \quad \mathbf{17.3 \ 0^\circ} \\ I_{L2} &= \sqrt{3} I_b \quad (90^\circ \ 30^\circ) \quad \mathbf{17.3 \ 120^\circ} \\ I_{L3} &= \sqrt{3} I_c \quad (150^\circ \ 30^\circ) \quad \mathbf{17.3 \ 120^\circ} \end{aligned}$$

These line currents have also been shown in Fig. 19.28 (b).

**Example 19.15.** Three similar coils, each having a resistance of 20 ohms and an inductance of 0.05 H are connected in (i) star (ii) mesh to a 3-phase, 50-Hz supply with 400-V between lines. Calculate the total power absorbed and the line current in each case. Draw the vector diagram of current and voltages in each case. **(Elect. Technology, Punjab Univ. 1990)**

**Solution.**  $X_L = 2 \pi f L = 2 \pi \times 50 \times 0.05 = 15 \ \Omega$ ,  $Z_{ph} = \sqrt{15^2 + 20^2} = 25 \ \Omega$

**(i) Star Connection.** [Fig. 19.29 (a)]

Fig. 19.29

$$V_{ph} = 400 / \sqrt{3} = 231 \text{ V}; I_{ph} = V_{ph} / Z_{ph} = 231 / 25 = \mathbf{9.24 \Omega}$$

$$I_L \quad I_{ph} \quad \mathbf{9.24 \text{ A}}; P = \sqrt{3} \quad 400 \quad 9.24 \quad (20/25) \quad \mathbf{5120 \text{ W}}$$

**(i) Delta Connection** [Fig. 19.29 (b)]

$$V_{ph} \quad V_L \quad 400 \text{ V}; I_{ph} \quad 400/25 \quad 16 \text{ A}; I_L \quad \sqrt{3} I_{ph} \quad \sqrt{3} \quad 16 \quad \mathbf{27.7 \text{ A}}$$

$$P = \sqrt{3} \times 400 \times 27.7 \times (20/25) = \mathbf{15,360 \text{ W}}$$

**Note.** It may be noted that line current as well as power are three times the star values.

**Example 19.16.** A  $\Delta$ -connected balanced 3-phase load is supplied from a 3-phase, 400-V supply. The line current is 20 A and the power taken by the load is 10,000 W. Find (i) impedance in each branch (ii) the line current, power factor and power consumed if the same load is connected in star. **(Electrical Machines, A.M.I.E. Sec. B. 1992)**

**Solution. (i) Delta Connection.**

$$V_{ph} = V_L = 400 \text{ V}; I_L = 20 \text{ A}; I_{ph} = 20 / \sqrt{3} \text{ A}$$

$$(i) \therefore Z_{ph} = \frac{400}{20/\sqrt{3}} = 20\sqrt{3} = \mathbf{34.64 \Omega}$$

$$\text{Now } P = \sqrt{3} V_L I_L \cos \phi \therefore \cos \phi = 10,000 / \sqrt{3} \times 400 \times 20 = \mathbf{0.7217}$$

**(ii) Star Connection**

$$V_{ph} = \frac{400}{\sqrt{3}}, I_{ph} = \frac{400/\sqrt{3}}{\sqrt{3}} = \frac{20}{3} \text{ A}, I_L = I_{ph} = \frac{20}{3} \text{ A}$$

Power factor remains the same since impedance is the same.

$$\text{Power consumed} = \sqrt{3} \times 400 \times (20/3) \times 0.7217 = \mathbf{3,330 \text{ W}}$$

**Note.** The power consumed is 1/3 of its value of  $\Delta$ -connection.

**Example 19.17.** Three similar resistors are connected in star across 400-V, 3-phase lines. The line current is 5 A. Calculate the value of each resistor. To what value should the line voltage be changed to obtain the same line current with the resistors delta-connected.

**Solution. Star Connection**

$$I_L = I_{ph} = 5 \text{ A}; V_{ph} = 400 / \sqrt{3} = 231 \text{ V} \therefore R_{ph} = 231 / 5 = \mathbf{46.2 \Omega}$$

**Delta Connection**

$$I_L = 5 \text{ A... (given)}; I_{ph} = 5 / \sqrt{3} \text{ A}; R_{ph} = \mathbf{46.2 \Omega}$$

... found above

$$V_{ph} \quad I_{ph} \quad R_{ph} \quad 5 \quad 46.2/\sqrt{3} \quad \mathbf{133.3 \text{ V}}$$

**Note.** Voltage needed is 1/3rd the star value.

**Example 19.18.** A balanced delta connected load, consisting of three coils, draws  $10\sqrt{3}$  A at 0.5 power factor from 100 V, 3-phase supply. If the coils are re-connected in star across the same supply, find the line current and total power consumed.

**(Elect. Technology, Punjab Univ. Nov.)**

**Solution. Delta Connection**

$$V_{ph} \quad V_L \quad 100 \text{ V}; I_L \quad 10\sqrt{3} \text{ A}; I_{ph} \quad 10\sqrt{3}/\sqrt{3} \quad \mathbf{10 \text{ A}}$$

$$Z_{ph} = V_{ph} / I_{ph} = 100/10 = 10\Omega; \cos\phi = 0.5 \text{ (given); } \sin\phi = 0.866$$

$$\therefore R_{ph} = Z_{ph} \cos\phi = 10 \times 0.5 = 5\Omega; X_{ph} = Z_{ph} \sin\phi = 10 \times 0.866 = 8.66\Omega$$

$$\text{Incidentally, total power consumed} = \sqrt{3} V_L I_L \cos\phi = \sqrt{3} \times 100 \times 10 \sqrt{3} \times 0.5 = 1500 \text{ W}$$

### Star Connection

$$V_{ph} = V_L / \sqrt{3} = 100 / \sqrt{3}; Z_{ph} = 10; I_{ph} = V_{ph} / Z_{ph} = 100 / \sqrt{3} \times 10 = 10 \sqrt{3} \text{ A}$$

$$\text{Total power absorbed} = \sqrt{3} \times 100 \times (10 \sqrt{3}) \times 0.5 = 500 \text{ W}$$

It would be noted that the line current as well as the power absorbed are one-third of that in the delta connection.

**Example 19.19.** Three identical impedances are connected in delta to a 3  $\phi$  supply of 400 V. The line current is 35 A and the total power taken from the supply is 15 kW. Calculate the resistance and reactance values of each impedance. *(Elect. Technology, Punjab Univ.,)*

$$\text{Solution. } V_{ph} = V_L = 400 \text{ V}; I_L = 35 \text{ A} \therefore I_{ph} = 35 / \sqrt{3} \text{ A}$$

$$Z_{ph} = V_{ph} / I_{ph} = 400 \times \sqrt{3} / 35 = 19.8 \text{ A}$$

Now,

$$\text{Power } P = \sqrt{3} V_L I_L \cos\phi \therefore \cos\phi = \frac{P}{\sqrt{3} V_L I_L} = \frac{15,000}{\sqrt{3} \times 400 \times 35} = 0.619; \text{ But } \sin\phi = 0.786$$

$$\therefore R_{ph} = Z_{ph} \cos\phi = 19.8 \times 0.619 = 12.25\Omega; X_{ph} = Z_{ph} \sin\phi = 19.8 \times 0.786 = 15.5\Omega$$

**Example 19.20.** Three  $100\Omega$  non-inductive resistances are connected in (a) star (b) delta across a 400-V, 50-Hz, 3-phase mains. Calculate the power taken from the supply system in each case. In the event of one of the three resistances getting open-circuited, what would be the value of total power taken from the mains in each of the two cases? *(Elect. Engg. A.M.Ae. S.I June, 1993)*

**Solution. (i) Star Connection [Fig. 19.30 (a)]**

$$V_{ph} = 400 / \sqrt{3} \text{ V}$$

$$P = \sqrt{3} V_L I_L \cos\phi \\ = \sqrt{3} \times 400 \times 4 \times 1 / \sqrt{3} = 1600 \text{ W}$$

**(ii) Delta Connection Fig. 19.30 (b)**

$$V_{ph} = 400 \text{ V}; R_{ph} = 100\Omega$$

$$I_{ph} = 400 / 100 = 4 \text{ A}$$

$$I_L = 4 \times \sqrt{3} \text{ A}$$

$$P = \sqrt{3} \times 400 \times 4 \times \sqrt{3} \times 1 = 4800 \text{ W}$$

**When one of the resistors is disconnected**

**(i) Star Connection [Fig. 19.28 (a)]**

The circuit no longer remains a 3-phase circuit but consists of two  $100\Omega$  resistors in series across a 400-V supply. Current in lines A and C is  $= 400/200 = 2 \text{ A}$

$$\text{Power absorbed in both} = 400 \times 2 = 800 \text{ W}$$

Hence, by disconnecting one resistor, the power consumption is reduced by half.

Fig. 19.30

**(ii) Delta Connection** [Fig. 19.28 (b)]

In this case, currents in  $A$  and  $C$  remain as usual  $120^\circ$  out of phase with each other.

Current in each phase =  $400/100 = 4$  A

Power consumption in both =  $2 \times 4^2 \times 100 = 3200$  W

(or  $P = 2 \times 4 \times 400 = 3200$  W)

In this case, when one resistor is disconnected, the power consumption is reduced by one-third.

**Example 19.21.** A 200-V, 3- $\phi$  voltage is applied to a balanced  $\Delta$ -connected load consisting of the groups of fifty 60-W, 200-V lamps. Calculate phase and line currents, phase voltages, power consumption of all lamps and of a single lamp included in each phase for the following cases :

(a) under normal conditions of operation

(b) after blowout in line  $R'R$  (c) after blowout in phase  $YB$

Neglect impedances of the line and internal resistances of the sources of e.m.f.

**Solution.** The load circuit is shown in Fig. 19.31 where each lamp group is represented by two lamps only. It should be kept in mind that lamps remain at the line voltage of the supply irrespective of whether the  $\Delta$ -connected load is balanced or not.

(a) **Normal operating conditions** [Fig. 19.31 (a)]

Since supply voltage equals the rated voltage of the bulbs, the power consumption of the lamps equals their rated wattage.

Power consumption/lamp = 60 W; Power consumption/phase =  $50 \times 60 = 3,000$  W

Phase current =  $3000/200 = 15$  A ; Line current =  $15 \times \sqrt{3} = 26$  A

(b) **Line Blowout** [Fig. 19.31 (b)]

When blowout occurs in line  $R$ , the lamp group of phase  $Y-B$  remains connected across line voltage  $V_{YB} = V_{YB}$ . However, the lamp groups of other two phases get connected in series across the same voltage  $V_{YB}$ . Assuming that lamp resistances remain constant, voltage drop across  $YR = V_{YB}/2 = 100$  V and that across  $RB = 100$  V.

Hence, phase currents are as under :

$$I_{YB} = 3000/200 = 15 \text{ A}, I_{YB} = I_{RB} = 15/2 = 7.5 \text{ A}$$

The line currents are :

$$I_{RR} = 0, I_{YY} = I_{BB} = I_{YB} = I_{YR} = 15 \quad 7.5 \quad 22.5 \text{ A}$$

Power in phase  $YR = 100 \times 7.5 = 750$  W; Power/lamp =  $750/50 = 15$  W

Power in phase  $YB = 200 \times 15 = 3000$  W ; Power/lamp =  $3000/50 = 60$  W

Power in phase  $RB = 100 \times 7.5 = 750$  W ; Power/lamp =  $750/50 = 15$  W

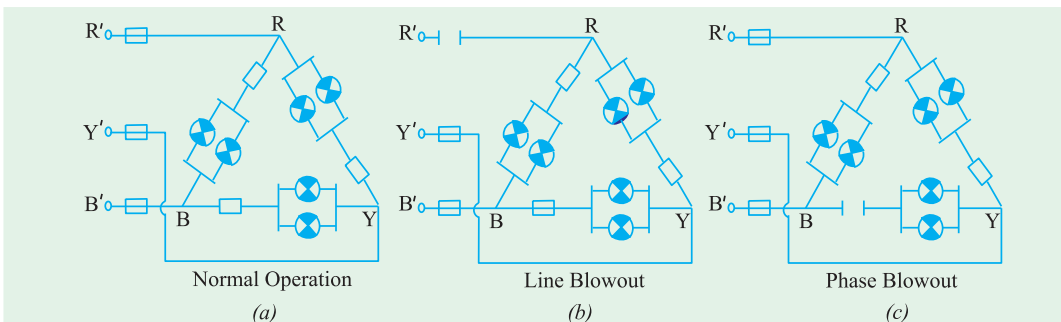

Fig. 19.31

**(c) Phase Blowout** [Fig. 19.31 (c)]

When fuse in phase *Y-B* blows out, the phase voltage becomes zero (though voltage across the open remains 200 V). However, the voltage across the other two phases remains the same as under normal operating conditions.

Hence, different phase currents are :

$$I_{RY} \quad 15 \text{ A}, I_{BR} \quad 15 \text{ A}, I_{YB} \quad 0$$

The line currents become

$$I_{RR} \quad 15\sqrt{3} \quad 26 \text{ A}; I_{YY} \quad 15 \text{ A}, I_{BB} \quad 15 \text{ A}$$

Power in phase *RY* = 200 × 15 = **3000 W**, Power/lamp = 3000/50 = **60 W**

Power in phase *RB* = 200 × 15 = **3000 W**, Power/lamp = 3000/50 = **60 W**

Power in phase *YB* = 0; power/lamp = 0.

**Example 19.22.** The load connected to a 3-phase supply comprises three similar coils connected in star. The line currents are 25 A and the kVA and kW inputs are 20 and 11 respectively. Find the line and phase voltages, the kVAR input and the resistance and reactance of each coil.

If the coils are now connected in delta to the same three-phase supply, calculate the line currents and the power taken.

**Solution. Star Connection**

$$\cos \phi \quad k = W/kVA = 11/20 \quad I_L = 25 \text{ A} \quad P = 11 \text{ kW} = 11,000 \text{ W}$$

$$\text{Now } P = \sqrt{3} V_L I_L \cos \phi \quad \therefore 11,000 = \sqrt{3} \times V_L \times 25 \times 11/20$$

$$\therefore V_L \quad 462 \text{ V}; \quad V_{ph} = 462 / \sqrt{3} = 267 \text{ V}$$

$$kVAR \quad \sqrt{kVA^2 - kW^2} \quad \sqrt{20^2 - 11^2} \quad 16.7; Z_{ph} \quad 267/2 \quad 10.68$$

$$\therefore R_{ph} = Z_{ph} \times \cos \phi = 10.68 \times 11/20 = 5.87 \Omega$$

$$\therefore X_{ph} = Z_{ph} \sin \phi = 10.68 \times 0.838 = 8.97 \Omega$$

**Delta Connection**

$$V_{ph} = V_L = 462 \text{ V} \text{ and } Z_{ph} = 10.68 \Omega$$

$$\therefore I_{ph} = 462/10.68 \text{ A}, I_L = \sqrt{3} \times 462/10.68 = 75 \text{ A}$$

$$P = \sqrt{3} \times 462 \times 75 \times 11/20 = 33,000 \text{ W}$$

**Example 19.23.** A 3-phase, star-connected system with 230 V between each phase and neutral has resistances of 4, 5 and 6 Ω respectively in the three phases. Estimate the current flowing in each phase and the neutral current. Find the total power absorbed. (I.E.E. London)

**Solution.** Here,  $V_{ph} = 230 \text{ V}$  [Fig. 19.32 (a)]

$$\text{Current in 4-}\Omega \text{ resistor} = 230/4 = 57.5 \text{ A}$$

$$\text{Current in 5-}\Omega \text{ resistor} = 230/5 = 46 \text{ A}$$

$$\text{Current in 6-}\Omega \text{ resistor} = 230/6 = 38.3 \text{ A}$$

Fig. 19.32

These currents are mutually displaced by  $120^\circ$ . The neutral current  $I_N$  is the vector sum\* of these three currents.  $I_N$  can be obtained by splitting up these three phase currents into their  $X$ -components and  $Y$ -components and then by combining them together, in diagram 19.32 (b).

$$X\text{-component} = 46 \cos 30^\circ - 38.3 \cos 30^\circ = \mathbf{6.64 \text{ A}}$$

$$Y\text{-component} = 57.5 - 46 \sin 30^\circ - 38.3 \sin 30^\circ = 15.3 \text{ A} \quad I_N = \sqrt{6.64^2 + 15.3^2} = \mathbf{16.71 \text{ A}}$$

$$\text{The power absorbed} = 230 (57.5 + 46 + 38.3) = \mathbf{32.610 \text{ W}}$$

**Example 19.24.** A 3-phase, 4-wire system supplies power at 400 V and lighting at 230 V. If the lamps in use require 70, 84 and 33 A in each of the three lines, what should be the current in the neutral wire? If a 3-phase motor is now started, taking 200 A from the line at a power factor of 0.2, what would be the current in each line and the neutral current? Find also the total power supplied to the lamps and the motor. (Elect. Technology, Aligarh Univ.)

**Solution.** The lamp and motor connections are shown in Fig. 19.33.

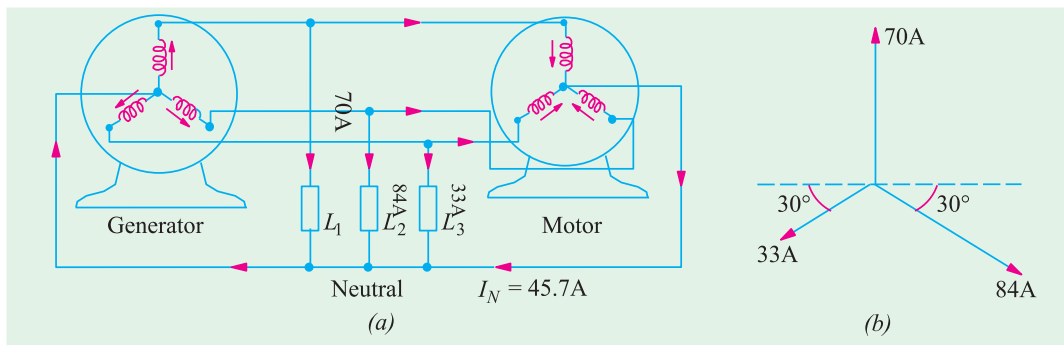

Fig. 19.33

#### When motor is not started

The neutral current is the vector sum of lamp currents. Again, splitting up the currents into their  $X$ - and  $Y$ -components, we get

$$X\text{-component} = 84 \cos 30^\circ - 33 \cos 30^\circ = 44.2 \text{ A}$$

$$Y\text{-component} = 70 - 84 \sin 30^\circ - 33 \sin 30^\circ = 11.5 \text{ A}$$

$$\therefore I_N = \sqrt{44.2^2 + 11.5^2} = \mathbf{45.7 \text{ A}}$$

#### When motor is started

A 3-phase motor is a balanced load. Hence, when it is started, it will change the line currents but being a balanced load, it contributes nothing to the neutral current. Hence, **the neutral current remains unchanged even after starting the motor.**

Now, the motor takes 200 A from the lines. It means that each line will carry motor current (which lags) as well as lamp current (which is in phase with the voltage). The current in each line would be the vector of sum of these two currents.

$$\text{Motor p.f.} = 0.2 ; \sin \phi = 0.9799 \dots \text{ from tables}$$

$$\text{Active component motor current} = 200 \times 0.2 = 40 \text{ A}$$

\* Some writers disagree with this statement on the ground that according to Kirchhoff's Current Law, at any junction,  $I_N + I_R + I_Y + I_B = 0 \therefore I_N = -(I_R + I_Y + I_B)$

Hence, according to them, numerical value of  $I_N$  is the same but its phase is changed by  $180^\circ$ .

Reactive component of motor current =  $200 \times 0.9799 = 196 \text{ A}$

(i) Current in first line =  $\sqrt{(40 + 70)^2 + 196^2} = \mathbf{224.8 \text{ A}}$

(ii) Current in second line =  $\sqrt{(40 - 84)^2 + 196^2} = \mathbf{232 \text{ A}}$

(iii) Current in third line =  $\sqrt{(40 + 33)^2 + 196^2} = \mathbf{210.6 \text{ A}}$

Power supplied to lamps =  $230 (33 + 84 + 70) = \mathbf{43,000 \text{ W}}$

Power supplied to motor =  $\sqrt{3} \times 200 \times 400 \times 0.2 = \mathbf{27,700 \text{ W}}$

### 19.11. Star and Delta connected Lighting Loads

In Fig. 19.34 (a) is shown a  $Y$ -connected lighting network in a three storey house. For such a load, it is essential to have neutral wire in order to ensure uniform distribution of load among the three phases despite random switching on and off or burning of lamps. It is seen from Fig. 19.34 (a),

Fig. 19.34

that network supplies two flats on each floor of the three storey residence and there is balanced distribution of lamp load among the three phases. There are house fuses at the cable entry into the building which protect the two mains against short-circuits in the main cable. At the flat entry, there are apartment (or flat) fuses in the single-phase supply which protect the two mains and other flats in the same building from short-circuits in a given building. There is no fuse (or switch) on the neutral wire of the mains because blowing of such a fuse (or disconnection of such a switch) would mean a break in the neutral wire. This would result in unequal voltages across different groups of lamps in case they have different power ratings or number. Consequently, filaments in one group would burn dim whereas in other groups they would burn too bright resulting in their early burn-out.

The house-lighting wire circuit for  $\Delta$ -connected lamps is shown in Fig. 19.34 (b).

### 19.12. Power Factor Improvement

The heating and lighting loads supplied from 3-phase supply have power factors, ranging

from 0.95 to unity. But motor loads have usually low lagging power factors, ranging from 0.5 to 0.9. Single-phase motors may have as low power factor as 0.4 and electric welding units have even lower power factors of 0.2 or 0.3.

The power factor is given by  $\cos \frac{\text{kW}}{\text{kVA}}$  or  $\text{kVA} = \frac{\text{kW}}{\cos}$

In the case of single-phase supply,  $\text{kVA} = \frac{VI}{1000}$  or  $I = \frac{1000 \text{ kVA}}{V} \therefore I \propto \text{kVA}$

In the case of 3-phase supply  $\text{kVA} = \frac{\sqrt{3} V_L I_L}{1000}$  or  $I_L = \frac{1000 \text{ kVA}}{\sqrt{3} \times V_L} \therefore I \propto \text{kVA}$

In each case, the kVA is directly proportional to current. The chief disadvantage of a low p.f. is that the current required for a given power, is very high. This fact leads to the following undesirable results.

**(i) Large kVA for given amount of power**

All electric machinery, like alternators, transformers, switchgears and cables are limited in their current-carrying capacity by the permissible temperature rise, which is proportional to  $I^2$ . Hence, they may all be fully loaded with respect to their rated kVA, without delivering their full power. Obviously, it is possible for an existing plant of a given kVA rating to increase its earning capacity (which is proportional to the power supplied in kW) if the overall power factor is improved *i.e.* raised.

**(ii) Poor voltage regulation**

When a load, having low lagging power factor, is switched on, there is a large voltage drop in the supply voltage because of the increased voltage drop in the supply lines and transformers. This drop in voltage adversely affects the starting torques of motors and necessitates expensive voltage stabilizing equipment for keeping the consumer's voltage fluctuations within the statutory limits. Moreover, due to this excessive drop, heaters take longer time to provide the desired heat energy, fluorescent lights flicker and incandescent lamps are not as bright as they should be. Hence, all supply undertakings try to encourage consumers to have a high power factor.

Switchgear

**Example 19.25.** A 50-MVA, 11-kV, 3- $\phi$  alternator supplies full load at a lagging power factor of 0.7. What would be the percentage increase in earning capacity if the power factor is increased to 0.95?

**Solution.** The earning capacity is proportional to the power (in MW or kW) supplied by the alternator.

MW supplied at 0.7 lagging =  $50 \times 0.7 = 35$

MW supplied at 0.95 lagging =  $50 \times 0.95 = 47.5$

increase in MW = 12.5

The increase in earning capacity is proportional to 12.5

$\therefore$  Percentage increase in earning capacity =  $(12.5/35) \times 100 = 35.7$

### 19.13. Power Correction Equipment

The following equipment is generally used for improving or correcting the power factor :

**(i) Synchronous Motors (or capacitors)**

These machines draw leading kVAR when they are over-excited and, especially, when they

are running idle. They are employed for correcting the power factor in bulk and have the special advantage that the amount of correction can be varied by changing their excitation.

**(ii) Static Capacitors**

They are installed to improve the power factor of a group of a.c. motors and are practically loss-free (*i.e.* they draw a current leading in phase by 90°). Since their capacitances are not variable, they tend to over-compensate on light loads, unless arrangements for automatic switching off the capacitor bank are made.

**(iii) Phase Advancers**

They are fitted with individual machines.

However, it may be noted that the economical degree of correction to be applied in each case, depends upon the tariff arrangement between the consumers and the supply authorities.

**Example 19.26.** A 3-phase, 37.3 kW, 440-V, 50-Hz induction motor operates on full load with an efficiency of 89% and at a power factor of 0.85 lagging. Calculate the total kVA rating of capacitors required to raise the full-load power factor at 0.95 lagging. What will be the capacitance per phase if the capacitors are (a) delta-connected and (b) star-connected ?

**Solution.** It is helpful to approach such problems from the ‘power triangle’ rather than from vector diagram viewpoint.

Motor power input  $P = 37.3/0.89 = 41.191 \text{ kW}$

**Power Factor 0.85 (lag)**

$\cos \phi_1 = 0.85; \phi_1 = \cos^{-1} (0.85) = 31.8^\circ; \tan \phi_1 = \tan 31.8^\circ = 0.62$

Motor  $\text{kVAR}_1 = P \tan \phi_1 = 41.91 \times 0.62 = 25.98$

**Power Factor 0.95 (lag)**

Motor power input  $P = 41.91 \text{ kW}$  ... as before

It is the same as before because capacitors are loss-free *i.e.* they do not absorb any power.

$\cos \phi_2 = 0.95 \therefore \phi_2 = 18.2^\circ; \tan 18.2^\circ = 0.3288$

Motor  $\text{kVAR}_2 = P \tan \phi_2 = 41.91 \times 0.3288 = 13.79$

The difference in the values of kVAR is due to the capacitors which supply **leading** kVAR to partially neutralize the **lagging** kVAR of the motor.

Fig. 19.35

$\therefore$  leading kVAR supplied by capacitors is  
 $= \text{kVAR}_1 - \text{kVAR}_2 = 25.98 - 13.79 = \mathbf{12.19}$  ... *CD* in Fig. 19.35 (b)  
 Since capacitors are loss-free, their kVAR is the same as kVA  
 $\therefore \text{kVA/capacitor} = 12.19/3 = 4.063 \therefore \text{VAR/capacitor} = 4,063$

(a) In  $\Delta$ -connection, voltage across each capacitor is 440 V

Current drawn by each capacitor  $I_c = 4063/440 = 9.23$  A

Now, 
$$I_c = \frac{V}{X_c} = \frac{V}{1/\omega C} = \omega VC$$

$\therefore C = I_c / \omega V = 9.23 / 2\pi \times 50 \times 440 = 66.8 \times 10^{-6} \text{ F} = \mathbf{66.8 \mu\text{F}}$

(b) In star connection, voltage across each capacitor is =  $440/\sqrt{3}$  volt

Current drawn by each capacitor,  $I_c = \frac{4063}{440/\sqrt{3}} = 16.0$  A

$$I_c = \frac{V}{X_c} = \omega VC \quad \text{or} \quad 16 = \frac{440}{\sqrt{3}} \times 2\pi \times 50 \times C$$

$\therefore C = 200.4 \times 10^{-6} \text{ F} = \mathbf{200.4 \mu\text{F}}$

**Note.** Star value is three times the delta value.

**Example 19.27.** If the motor of Example 19.24 is supplied through a cable of resistance  $0.04 \Omega$  per core, calculate

(i) the percentage reduction in cable Cu loss and

(ii) the additional balanced lighting load which the cable can supply when the capacitors are connected.

**Solution.** Original motor  $\text{kVA}_1 = P/\cos \phi_1 = 41.91/0.85 = 49.3$

Original line current,  $I_{L1} = \frac{\text{kVA}_1 \times 1000}{\sqrt{3} \times 440} = \frac{49.3 \times 1000}{\sqrt{3} \times 440} = 64.49$  A

$\therefore$  Original Cu loss/conductor =  $64.49^2 \times 0.04 = 167.4$  W

From Fig. 19.34, it is seen that the new kVA i.e.  $\text{kVA}_2$  when capacitors are connected is given by  $\text{kVA}_2 = \text{kW}/\cos \phi_2 = 41.91/0.95 = 44.12$

New line current  $I_{L2} = \frac{44,120}{\sqrt{3} \times 440} = 57.89$  A

New Cu loss =  $57.89^2 \times 0.04 = 134.1$  W

(i)  $\therefore$  percentage reduction =  $\frac{167.4 - 134.1}{167.4} \times 100 = \mathbf{19.9}$

The total kVA which the cable can supply is 49.3 kVA. When the capacitors are connected, the kVA supplied is 44.12 at a power factor of 0.94 lagging. The lighting load will be assumed at unity power factor. The kVA diagram is shown in Fig. 19.34. We will tabulate the different loads as follows. Let the additional lighting load be  $x$  kW.

Fig. 19.36

Load	kVA	$\cos \phi$	kW	$\sin \phi$	kVAR
Motor	49.3	0.85 lag	41.91	0.527	-25.98
Capacitors	12.19	0 lead	0	1.0	+12.19
Lighting	-	1.0	$x$	0	0
			$(1.91 + x)$		-13.79

From Fig. 19.36 it is seen that

$$AF = 41.91 + x \text{ and } EF = 13.79 \quad AE = \text{resultant kVA} = 49.3$$

$$\text{Also } AF^2 + EF^2 = AE^2 \text{ or } (41.91 + x)^2 + 13.79^2 = 49.3^2 \quad \therefore x = \mathbf{5.42 \text{ kW}}$$

**Example 19.28.** Three impedance coils, each having a resistance of  $20\Omega$  and a reactance of  $15\Omega$ , are connected in star to a 400-V, 3- $\phi$ , 50-Hz supply. Calculate (i) the line current (ii) power supplied and (iii) the power factor.

If three capacitors, each of the same capacitance, are connected in delta to the same supply so as to form parallel circuit with the above impedance coils, calculate the capacitance of each capacitor to obtain a resultant power factor of 0.95 lagging.

$$\text{Solution. } V_{ph} = 400/\sqrt{3}V, Z_{ph} = \sqrt{20^2 + 15^2} = 25$$

$$\cos \phi_1 = R_{ph}/Z_{ph} = 20/25 = 0.8 \text{ lag; } \phi_1 = 0.6 \text{ lag}$$

where  $\phi_1$  is the power factor angle of the coils.

**When capacitors are not connected**

$$(i) I_{ph} = 400/25 \times \sqrt{3} = 9.24 \text{ A} \quad \therefore I_L = \mathbf{9.24 \text{ A}}$$

$$(ii) P = \sqrt{3} V_L I_L \cos \phi_1 = \sqrt{3} \times 400 \times 9.24 \times 0.8 = \mathbf{5.120 \text{ W}}$$

$$(iii) \text{ Power factor} = \mathbf{0.8 \text{ (lag)}}$$

$$\therefore \text{ Motor VAR}_1 = \sqrt{3} V_L I_L \sin \phi_1 = \sqrt{3} \times 400 \times 9.24 \times 0.6 = \mathbf{3,840}$$

**When capacitors are connected**

$$\text{Power factor, } \cos \phi_2 = 0.95, \phi_2 = 18.2^\circ; \tan 18.2^\circ = 0.3288$$

Since capacitors themselves do not absorb any power, power remains the same *i.e.* 5,120 W even when capacitors are connected. The only thing that changes is the VAR.

$$\text{Now } \text{VAR}_2 = P \tan \phi_2 = 5120 \times 0.3288 = 1684$$

**Leading VAR** supplied by the three capacitors is

$$= \text{VAR}_1 - \text{VAR}_2 = 3840 - 1684 = 2156 \text{ BD or CE in Fig 19.37 (b)}$$

$$\text{VAR/ Capacitor} = 2156/3 = 719$$

$$\text{For delta connection, voltage across each capacitor is } 400 \text{ V} \quad \therefore I_c = 719/400 = 1.798 \text{ A}$$

Fig. 19.37

$$\text{Also } I_c = \frac{V}{I/\omega C} = \omega VC \quad \therefore C = 1.798/\pi \times 50 \times 400 = 14.32 \times 10^{-6} \text{ F} = \mathbf{14.32 \mu\text{F}}$$

### 19.14. Parallel Loads

A combination of balanced 3-phase loads connected in parallel may be solved by any one of the following three methods :

1. All the given loads may be converted into equivalent  $\Delta$ -loads and then combined together according to the law governing parallel circuits.
2. All the given loads may be converted into equivalent  $Y$ -loads and treated as in (1) above.
3. The third method, which requires less work, is to work in terms of volt-amperes. The special advantage of this approach is that voltmeters can be added regardless of the kind of connection involved. The real power of various loads can be added arithmetically and VARs may be added algebraically so that total voltamperes are given by

$$VA = \sqrt{W^2 + VAR^2} \quad \text{or} \quad S = \sqrt{P^2 + Q^2}$$

where  $P$  is the power in watt and  $Q$  represents reactive voltamperes.

**Example 19.29.** For the power distribution system shown in Fig. 19.38, find

(a) total apparent power, power factor and magnitude of the total current  $I_T$  without the capacitor in the system

(b) the capacitive kVARs that must be supplied by  $C$  to raise the power factor of the system to unity ;

(c) the capacitance  $C$  necessary to achieve the power correction in part (b) above

(d) total apparent power and supply current  $I_T$  after the power factor correction.

**Solution.** (a) We will take the inductive i.e. lagging kVARs as negative and capacitive i.e. leading kVARs as positive.

$$\text{Total } Q = -16 + 6 - 12 = -22 \text{ kVAR (lag)}; \text{ Total } P = 30 + 4 + 36 = 70 \text{ kW}$$

$$\therefore \text{apparent power } S = \sqrt{(-22)^2 + 70^2} = \mathbf{73.4 \text{ kVA}}; \text{ p.f.} = \cos \phi = P/S = 70/73.4 = \mathbf{0.95}$$

$$S = VI_T \text{ or } 73.4 \times 10^3 = 400 \times I_T \therefore I_T = \mathbf{183.5 \text{ A}}$$

(b) Since total lagging kVARs are  $-22$ , hence, for making the power factor unity, 22 leading kVARs must be supplied by the capacitor to neutralize them. In that case, total  $Q = 0$  and  $S = P$  and p.f. is unity.

(c) If  $I_C$  is the current drawn by the capacitor, then  $22 \times 10^3 = 400 \times I_C$

$$\text{Now, } I_C = V/X_C = V\omega C$$

$$= 400 \times 2\pi \times 50 \times C$$

$$\therefore 22 \times 10^3 = 400 (2\pi \times 50 C);$$

$$\therefore C = \mathbf{483 \mu F}$$

(d) Since  $Q = 0$ ,

$$\text{hence, } S = \sqrt{10^2 + 70^2} = \mathbf{70 \text{ kVA}}$$

$$\text{Now, } VI_T = 70 \times 10^3;$$

$$I_T = 70 \times 10^3 / 400 = 175 \text{ A.}$$

It would be seen that after the power correction, lesser amount of current is required to deliver the same amount of real power to the system.

**Example 19.30.** A symmetrical 3-phase, 3-wire supply with a line voltage of 173 V supplies two balanced 3-phase loads; one  $Y$ -connected with each branch impedance equal to  $(6 + j8)$  ohm and the other  $\Delta$ -connected with each branch impedance equal to  $(18 + j24)$  ohm. Calculate

(i) the magnitudes of branch currents taken by each 3-phase load

Fig. 19.38

(ii) the magnitude of the total line current and

(iii) the power factor of the entire load circuit

Draw the phasor diagram of the voltages and currents for the two loads.

(Elect. Engineering-I, Bombay Univ.)

**Solution.** The equivalent  $Y$ -load of the given  $\Delta$ -load (Art.19.10) is  $= (18 + j24)/3 = (6 + j8) \Omega$

With this, the problem now reduces to one of solving two equal  $Y$ -loads connected in parallel across the 3-phase supply as shown in Fig. 19.39 (a). Phasor diagram for the combined load for one phase only is given in Fig. 19.39 (b).

Combined load impedance

$$= (6 + j8) / 2 = 3 + j4$$

$$= 5 \angle 53.1^\circ \text{ ohm}$$

$$V_{ph} = 173 / \sqrt{3} = 100 \text{ V}$$

Let  $V_{ph} = 100 \angle 0^\circ$

$$\therefore I_{ph} = \frac{100 \angle 0^\circ}{5 \angle 53.1^\circ} = 20 \angle -53.1^\circ$$

Current in each load  $= 10 \angle -53.1^\circ \text{ A}$

(i) branch current taken by each load is **10 A**; (ii) line current is **20 A**;

(iii) combined power factor  $= \cos 53.1^\circ = \mathbf{0.6 \text{ (lag)}}$ .

Fig. 19.39

**Example 19.31.** Three identical impedances of  $30 \angle 30^\circ$  ohms are connected in delta to a 3-phase, 3-wire, 208 V volt abc system by conductors which have impedances of  $(0.8 + j 0.63)$  ohm. Find the magnitude of the line voltage at the load end.

(Elect. Engg. Punjab Univ. May 1990)

**Solution.** The equivalent  $Z_y$  of the given  $Z_\Delta$  is  $30 \angle 30^\circ / 3 = 10 \angle 30^\circ = (8.86 + j5)$ . Hence, the load connections become as shown in Fig. 19.40.

$$Z_{an} = (0.8 + j0.6) + (8.86 + j5)$$

$$= 9.66 + j5.6 = 11.16 \angle 30.1^\circ$$

$$V_{an} = V_{ph} = 208 / \sqrt{3} = 120 \text{ V}$$

Let  $V_{an} = 120 \angle 0^\circ$

$$\therefore I_{an} = 120 \angle 0^\circ / 11.16 \angle 30.1^\circ = 10.75 \angle -30.1^\circ$$

Now,  $Z_{aa'} = 0.8 + j0.6 = 1 \angle 36.9^\circ$

Voltage drop on line conductors is

$$V'_{aa} = I_{an} Z'_{aa} = 10.75 \angle -30.1^\circ \times 1 \angle 36.9^\circ = 10.75 \angle 6.8^\circ = 10.67 + j1.27$$

$$\therefore V'_{an} = V_{an} - V'_{aa} = (120 + j0) - (10.67 + j1.27) = \mathbf{109.3 \quad 2.03^\circ}$$

Fig. 19.40

**Example 19.32.** A balanced delta-connected load having an impedance  $Z_L = (300 + j210)$  ohm in each phase is supplied from 400-V, 3-phase supply through a 3-phase line having an impedance of  $Z_s = (4 + j8)$  ohm in each phase. Find the total power supplied to the load as well as the current and voltage in each phase of the load.

(Elect. Circuit Theory, Kerala Univ.)

**Solution.** The equivalent  $Y$ -load of the given  $\Delta$ -load is

$$= (300 + j210) / 3 = (100 + j70) \Omega$$

Hence, connections become as shown in Fig. 19.41

$$\mathbf{Z}_{a0} \quad (4 \quad j8) \quad (100 \quad j70) \quad 104 \quad j78 \quad 130 \quad 36.9$$

$$\mathbf{V}_{a0} \quad 400/\sqrt{3} \quad 231V,$$

$$\mathbf{I}_{a0} \quad 231 \quad 0 \quad /130 \quad 36.9 \quad 1.78 \quad 36.9$$

$$\text{Now, } \mathbf{Z}'_{a0} = (4 + j8) = 8.94 \angle 63.4^\circ$$

$$\text{Line drop } \mathbf{V}_{aa} \quad \mathbf{I}_{aa} \mathbf{Z}_{aa} \quad 1.78 \quad 36.9 \quad 8.94 \quad 63.4 \quad 15.9 \quad 26.5 \quad 14.2 \quad j7.1$$

$$\mathbf{V}_{a0} \quad \mathbf{V}_{a0} \quad \mathbf{V}_{aa} \quad (231 \quad j0) \quad (14.2 \quad j7.1)$$

$$= (216.8 - j7.1) = 216.9 \angle -1^\circ 52'$$

Phase voltage at load end,  $V_{a0} = 216.9 \text{ V}$

Phase current at load end,  $I_{a0} = 1.78 \text{ A}$

Power supplied to load =  $3 \times 1.782 \times 100 = 951 \text{ W}$

Incidentally, line voltage at load end  $V_{ac} = 216.9 \times \sqrt{3} = 375.7 \text{ V}^*$

**Example 19.33.** A star connected load having  $R = 42.6$  ohms/phase and  $X_L = 32$  ohms/phase is connected across 400 V, 3 phase supply, calculate:

- Line current, reactive power and power loss
- Line current when one of load becomes open circuited.

[Nagpur University, Summer 2001]

**Solution.**

$$(i) \quad \mathbf{Z} = 42.6 + j32$$

$$|\mathbf{Z}| = 53.28 \text{ ohms, Impedance angle, } \theta = \cos^{-1} \left( \frac{42.6}{53.28} \right) = \cos^{-1} 0.80$$

$$\theta = 36.9^\circ$$

Line Current = phase current, due to star-connection

$$= \frac{\text{Voltage/phase}}{\text{Impedance/phase}} = \frac{400/\sqrt{3}}{53.28} = 4.336 \text{ amp}$$

Due to the phase angle of  $36.9^\circ$  lagging,

Reactive Power for the three-phases

$$= 3 V_{ph} I_{ph} \sin \phi = 3 \times 231 \times 4.336 \times 0.6 = 1803 \text{ VAR}$$

$$\text{Total Power-loss} = 3 V_{ph} I_{ph} \cos \phi = 3 \times 231 \times 4.336 \times 0.8 = 2404 \text{ watts}$$

(ii) One of the Loads is open-circuited.

The circuit is shown in Fig. 19.42 (b).

Fig. 19.41

Fig. 19.42 (a)

\* It should be noted that total line drop is not the numerical sum of the individual line drops because they are  $120^\circ$  out of phase with each other. By a laborious process  $\mathbf{V}_{ac} = \mathbf{V}'_{ac} - \mathbf{V}'_{aa} - \mathbf{V}'_{ac}$ .

Between A and B, the Line voltage of 400 V drives a current through two “phase-impedances” in series.

Total Impedance between A and B =  $(42.6 + j 32) \times 2$  ohms

Hence, the line current I for the two Lines A and B

$$= \frac{400}{2 \times 53.25} = 3.754 \text{ amp}$$

**Note :** Third Line ‘C’ does not carry any current.

**Example 19.34.** Three non-inductive resistances, each of 100 ohms, are connected in star to a three-phase, 440-V supply. Three inductive coils, each of reactance 100 ohms connected in delta are also connected to the supply. Calculate: (i) Line-currents, and (ii) power factor of the system

[Nagpur University, November 1998]

**Solution. (a)** Three resistances are connected in star. Each resistance is of 100 ohms and 254 – V appears across it. Hence, a current of 2.54 A flows through the resistors and the concerned power-factor is unity. Due to star-connection,

Line-current = Phase-current = 2.54A

**(b)** Three inductive reactance are delta connected.

Line-Voltage = Phase – Voltage = 440 V

Phase Current =  $440/100 = 4.4$  A

Line current =  $1.732 \times 4.4 = 7.62$  A

The current has a zero lagging power-factor.

Total Line Current =  $2.54 - j 7.62$  A

= 8.032 A, in each of the lines.

Power factor =  $2.54/8.032 = 0.32$  Lag.

Fig. 19.43

**Example 19.35.** The delta-connected generator of Fig 19.44 has the voltage;  $V_{RY} = 220 \angle 0^\circ$ ,  $V_{YB} = 220 \angle -120^\circ$  and  $V_{BR} = 220 \angle -240^\circ$  Volts.

The load is balanced and delta-connected. Find:

(a) Impedance per phase, (b) Current per phase, (c) Other line – currents  $I_Y$  and  $I_B$

[Nagpur University, November 1997]

**Solution.** Draw phasors for voltages as mentioned in the data.  $V_{RY}$  naturally becomes a reference-phasor, along which the phasor  $I_R$  also must lie, as shown in Fig. 19.44 (b) & (c).  $I_R$  is the line voltage which is related to the phase-currents  $I_{RY}$  and  $-I_{BR}$ . In terms of magnitudes,

$$|I_{RY}| = |I_{BR}| = |I_R|/\sqrt{3} = 10/\sqrt{3} = 5.8 \text{ Amp}$$

Thus,  $I_{RY}$  leads  $V_{RY}$  by  $30^\circ$ . This can take place only with a series combination of a resistor and a capacitor, as the simplest impedance in each phase

Fig. 19.42 (b) One phase open circuited

Fig 19.44 (a)

Fig. 19.44 (b)

Fig. 19.44 (c)

(a)  $|Z| = 220/5.8 = 38.1$  ohms

Resistance per phase =  $38.1 \times \cos 30^\circ = 33$  ohms

Capacitive Reactance/phase =  $38.1 \times \sin 30^\circ = 19.05$  ohms

(b) Current per phase = 5.8 amp, as calculated above.

(c) Otherline currents: Since a symmetrical three phase system is being dealt with, three currents have a mutual phase-difference of  $120^\circ$ . Hence

$I_R = 10 \angle 0^\circ$  as given,  $I_Y = 10 \angle -120^\circ$  amp;  $I_B = 10 \angle -240^\circ$  amp.

**Example 19.36.** A balanced 3-phase star-connected load of  $8 + j6$  ohms per phase is connected to a three-phase 230 V supply. Find the line-current, power-factor, active power, reactive-power, and total volt-amperes.

[Rajiv Gandhi Technical University, Bhopal, April 2001]

**Solution.** When a statement is made about three-phase voltage, when not mentioned otherwise, the voltage is the line-to-line voltage. Thus, 230 V is the line voltage, which means, in star-system, phase-voltage is  $230/1.732$ , which comes to 132.8 V.

$|Z| = \sqrt{8^2 + 6^2} = 10$  ohms

Line current = Phase current

=  $132.8/10 = 13.28$  amp

Power - factor =  $R/Z = 0.8$ , Lagging

Total Active Power =  $P = 1.732 \times$  Line Voltage  $\times$  Line Current  $\times$  P.f.

Or =  $3 \times$  Phase Voltage  $\times$  Phase-current  $\times$  P.f

=  $3 \times 132.8 \times 13.28 \times 0.8 = 4232$  watts

Fig. 19.45

Total Reactive Power =  $Q$

$$= 3 \times \text{Phase-voltage} \times \text{Phase-current} \times \sin \phi$$

$$= 3 \times 132.8 \times 13.28 \times 0.60 = 3174 \text{ VAR}$$

$$\text{Total Volt-amperes} = S = \sqrt{P^2 + Q^2} = 5290 \text{ VA}$$

$$\text{Or } S = \sqrt{3} \times 230 \times 13.28 = 5290 \text{ VA}$$

**Example 19.37.** A balanced three-phase star connected load of 100 kW takes a leading current of 80 amp, when connected across a three-phase 1100 V, 50 Hz, supply. Find the circuit constants of the load per phase. [Nagpur University, April 1996]

**Solution.** Voltage per phase =  $1100/1.732 = 635 \text{ V}$

Impedance =  $635/80 = 7.94 \text{ ohms}$ .

Due to the leading current, a capacitor exists.

Resistance  $R$  can be evaluated from current and power consumed

$$3 I^2 R = 100 \times 1000, \text{ giving } R = 5.21 \text{ ohms}$$

$$X_c = (7.94^2 - 5.21^2)^{0.5} = 6 \text{ ohms}$$

At 50 Hz,  $C = 1/(314 \times 6) = 531 \text{ microfarads}$ .

### Tutorial Problem No. 19.1

1. Each phase of a delta-connected load comprises a resistor of  $50 \Omega$  and capacitor of  $50 \mu\text{F}$  in series. Calculate (a) the line and phase currents (b) the total power and (c) the kilovoltamperes when the load is connected to a 440-V, 3-phase, 50-Hz supply. [(a) 9.46 A; 5.46 A (b) 4480 W (c) 7.24 kVA]

2. Three similar-coils,  $A$ ,  $B$  and  $C$  are available. Each coil has  $9 \Omega$  resistance and  $12 \Omega$  reactance. They are connected in delta to a 3-phase, 440-V, 50-Hz supply. Calculate for this load:

- (a) the line current (b) the power factor  
 (c) the total kilovolt-amperes (d) the total kilowatts

If the coils are reconnected in star, calculate for the new load the quantities named at (a), (b); (c) and (d) above. [50.7 A; 0.6; 38.6 kVA; 23.16 kW; 16.9 A; 0.6; 12.867 kVA; 7.72 kW]

3. Three similar choke coils are connected in star to a 3-phase supply. If the line currents are 15 A, the total power consumed is 11 kW and the volt-ampere input is 15 kVA, find the line and phase voltages, the VAR input and the reactance and resistance of each coil.

[577.3 V; 333.3 V; 10.2 kVAR; 15.1  $\Omega$ ; 16.3  $\Omega$ ]

4. The load in each branch of a delta-connected balanced 3- $\phi$  circuit consists of an inductance of  $0.0318 \text{ H}$  in series with a resistance of  $10 \Omega$ . The line voltage is  $400 \text{ V}$  at  $50 \text{ Hz}$ . Calculate (i) the line current and (ii) the total power in the circuit. [(i) 49 A (ii) 24 kW] (London Univ.)

5. A 3-phase, delta-connected load, each phase of which has  $R = 10 \Omega$  and  $X = 8 \Omega$ , is supplied from a star-connected secondary winding of a 3-phase transformer each phase of which gives  $230 \text{ V}$ . Calculate

- (a) the current in each phase of the load and in the secondary windings of the transformer  
 (b) the total power taken by the load  
 (c) the power factor of the load. [(a) 31.1 A; 54 A (b) 29 kW (c) 0.78]

6. A 3-phase load consists of three similar inductive coils, each of resistance  $50 \Omega$  and inductance  $0.3 \text{ H}$ . The supply is  $415 \text{ V}$ ,  $50 \text{ Hz}$ , Calculate (a) the line current (b) the power factor and (c) the total power when the load is (i) star-connected and (ii) delta-connected.

[(i) 2.25 A, 0.47 lag, 762 W (ii) 6.75 A, 0.47 lag, 2280 W] (London Univ.)

7. Three  $20 \Omega$  non-inductive resistors are connected in star across a three phase supply the line voltage of which is  $480 \text{ V}$ . Three other equal non-inductive resistors are connected in delta across the same supply so as to take the same-line current. What are the resistance values of these other resistors and what is the current- flowing through each of them? [60  $\Omega$ ; 8A] (Sheffield Univ. U.K.)

**8.** A 415-V, 3-phase, 4-wire system supplies power to three non-inductive loads. The loads are 25 kW between red and neutral, 30 kW between yellow and neutral and 12 kW between blue and neutral. Calculate (a) the current in each-line wire and (b) the current in the neutral conductor.

**[(a) 104.2 A, 125 A, 50 A (b) 67 A] (London Univ.)**

**9.** Non-inductive loads of 10, 6 and 4 kW are connected between the neutral and the red, yellow and blue phases respectively of a three-phase, four-wire system. The line voltage is 400 V. Find the current in each line conductor and in the neutral.

**[(a) 43.3 A, 26A, 173. A, 22.9] (App. Elect. London Univ.)**

**10.** A three-phase, star-connected alternator supplies a delta-connected load, each phase of which has a resistance of  $20\ \Omega$  and a reactance of  $10\ \Omega$ . Calculate (a) the current supplied by the alternator (b) the output of the alternator in kW and kVA, neglecting the losses in the lines between the alternator and the load. The line voltage is 400 V.

**[(a) 30.95 A (b) 19.2 kW, 21.45 kVA]**

**11.** Three non-inductive resistances, each of  $100\ \Omega$ , are connected in star to 3-phase, 440-V supply. Three equal choking coils each of reactance  $100\ \Omega$  are also connected in delta to the same supply. Calculate:

(a) line current (b) p.f. of the system. **[(a) 8.04 A (b) 0.3156] (I.E.E. London)**

**12.** In a 3-phase, 4-wire system, there is a balanced 3-phase motor load taking 200 kW at a power factor of 0.8 lagging, while lamps connected between phase conductors and the neutral take 50, 70 and 100 kW respectively. The voltage between phase conductors is 430 V. Calculate the current in each phase and in the neutral wire of the feeder supplying the load.

**[512 A, 5.87 A, 699 A; 213.3 A] (Elect. Power; London Univ.)**

**13.** A 440-V, 50-Hz induction motor takes a line current of 45 A at a power factor of 0.8 (lagging). Three  $\Delta$ -connected capacitors are installed to improve the power factor to 0.95 (lagging). Calculate the kVA of the capacitor bank and the capacitance of each capacitor.

**[11.45 kVA, 62.7  $\mu$ F] (I.E.E. London)**

**14.** Three resistances, each of  $500\ \Omega$  are connected in star to a 400-V, 50-Hz, 3-phase supply. If three capacitors, when connected in delta to the same supply, take the same line currents, calculate the capacitance of each capacitor and the line current.

**[2.123  $\mu$  F, 0.653 A] (London Univ.)**

**15.** A factory takes the following balanced loads from a 440-V, 3-phase, 50-Hz supply:

(a) a lighting load of 20 kW (b) a continuous motor load of 30 kVA at 0.5 p.f. lagging.  
(c) an intermittent welding load of 30 kVA at 0.5 p.f. lagging.

Calculate the kVA rating of the capacitor bank required to improve the power factor of loads (a) and (b) together to unity. Give also the value of capacitor required in each phase if a star-connected bank is employed.

What is the new overall p.f. if, after correction has been applied, the welding load is switched on.

**[30 kVAR; 490 $\mu$  F; 0.945 kg]**

**16.** A three-wire, three-phase system, with 400 V between the line wires, supplies a balanced delta-connected load taking a total power of 30 kW at 0.8 power factor lagging. Calculate (i) the resistance and (ii) the reactance of each branch of the load and sketch a vector diagram showing the line voltages and line currents. If the power factor of the system is to be raised to 0.95 lagging by means of three delta-connected capacitors, calculate (iii) the capacitance of each branch assuming the supply frequency to be 50 Hz.

**[(i) 10.24 A (ii) 7.68  $\Omega$  (iii) 83.2  $\mu$ F] (London Univ.)**

### 19.15. Power Measurement in 3-phase Circuits

Following methods are available for measuring power in a 3-phase load.

#### (a) Three Wattmeter Method

In this method, three wattmeters are inserted one in each phase and the algebraic sum of their readings gives the total power consumed by the 3-phase load.

#### (b) Two Wattmeter Method

(i) This method gives true power in the 3-phase circuit without regard to balance or wave form provided in the case of Y-connected load. The neutral of the load is isolated from the neutral of the source of power. Or if there is a neutral connection, the neutral wire should not carry any current. This is possible only if the load is perfectly balanced and there are no harmonics present of triple frequency or any other multiples of that frequency.

- (ii) This method can also be used for 3-phase, 4-wire system in which the neutral wire carries the neutral current. In this method, the current coils of the wattmeters are supplied from current transformers inserted in the principal line wires in order to get the correct magnitude and phase differences of the currents in the current coils of the wattmeter, because in the 3-phase, 4-wire system, the sum of the instantaneous currents in the principal line wires is not necessarily equal to zero as in 3-phase 3-wire system.

### (c) One Wattmeter Method

In this method, a single wattmeter is used to obtain the two readings which are obtained by two wattmeters by the two-wattmeter method. This method can, however, be used only when the load is balanced.

## 19.16. Three Wattmeter Method

A wattmeter consists of (i) a low resistance current coil which is inserted in series with the line carrying the current and (ii) a high resistance pressure coil which is connected across the two points whose potential difference is to be measured.

A wattmeter shows a reading which is proportional to the product of the current through its current coil, the p.d. across its potential or pressure coil and cosine of the angle between this voltage and current.

As shown in Fig. 19.46 in this method three wattmeters are inserted in each of the three phases of the load whether  $\Delta$ -connected or  $Y$ -connected. The current coil of each wattmeter carries the current of one phase only and the pressure coil measures the phase-voltage of this phase. Hence, each wattmeter measures the power in a single phase. The algebraic sum of the readings of three wattmeters must give the total power in the load.

Fig. 19.46

The difficulty with this method is that under ordinary conditions it is not generally feasible to break into the phases of a delta-connected load nor is it always possible, in the case of a  $Y$ -connected load, to get at the neutral point which is required for connections as shown in Fig. 19.47 (b). However, it is not necessary to use three wattmeters to measure power, two wattmeters can be used for the purpose as shown below.

## 19.17. Two Wattmeter Method-Balanced or Unbalanced Load

As shown in Fig. 19.41, the current coils of the two wattmeters are inserted in *any two* lines and the potential coil of each joined to the third line. It can be proved that the sum of the instantaneous powers indicated by  $W_1$  and  $W_2$  gives the instantaneous power absorbed by the three loads  $L_1$ ,  $L_2$  and  $L_3$ . A star-connected load is considered in the following discussion although it can be equally applied to  $\Delta$ -connected loads because a  $\Delta$ -connected load can always be replaced by an equivalent  $Y$ -connected load.

Now, before we consider the currents through and p.d. across each wattmeter, it may be pointed out that *it is important to take the direction of the voltage through the circuit the same as that taken for the current when establishing the readings of the two wattmeters.*

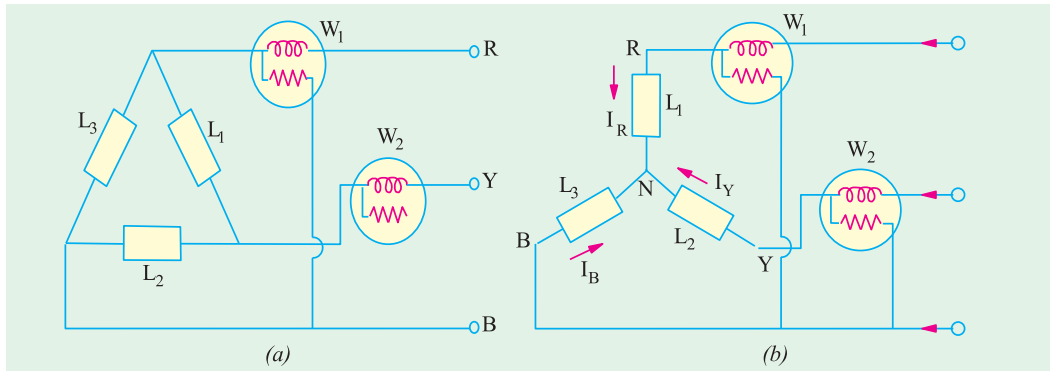

Fig. 19.47

**Instantaneous** current through  $W_1 = i_R$

p.d. across  $W_1 = e_{RB} = e_R - e_B$

p.d. across power read by  $W_1 = i_R (e_R - e_B)$

**Instantaneous** current through  $W_2 = i_Y$

**Instantaneous** p.d. across  $W_2 = e_{YB} = (e_Y - e_B)$

**Instantaneous** power read by  $W_2 = i_Y (e_Y - e_B)$

$$\therefore W_1 + W_2 = e_R(e_R - e_B) + i_Y(e_Y - e_B) = i_R e_R + i_Y e_Y - e_B(i_R + i_Y)$$

Now,  $i_R + i_Y + i_B = 0$  ... Kirchhoff's Current Law

$$\therefore i_R + i_Y = -i_B$$

$$\text{or } W_1 + W_2 = i_R \cdot e_R + i_Y \cdot e_Y + i_B \cdot e_B = p_1 + p_2 + p_3$$

where  $p_1$  is the power absorbed by load  $L_1$ ,  $p_2$  that absorbed by  $L_2$  and  $p_3$  that absorbed by  $L_3$

$$\therefore W_1 + W_2 = \text{total power absorbed}$$

The proof is true whether the load is balanced or unbalanced. If the load is Y-connected, it should have no neutral connection (i.e. 3- $\phi$ , 3-wire connected) and if it has a neutral connection (i.e. 3- $\phi$ , 4-wire connected) then it should be exactly balanced so that in each case there is no neutral current  $i_N$  otherwise Kirchhoff's current law will give  $i_N + i_R + i_Y + i_B = 0$ .

We have considered **instantaneous** readings, but in fact, the moving system of the wattmeter, due to its inertia, cannot quickly follow the variations taking place in a cycle, hence it indicates the **average** power.

$$\therefore W_1 = \frac{1}{T} \int_0^T i_R e_{RB} dt \quad W_2 = \frac{1}{T} \int_0^T i_Y e_{YB} dt$$

### 19.18. Two Wattmeter Method—Balanced Load

If the load is balanced, then power factor of the load can also be found from the two wattmeter readings. The Y-connected load in Fig. 19.47 (b) will be assumed inductive. The vector diagram for such a balanced Y-connected load is shown in Fig. 19.48. We will now consider the problem in terms of r.m.s. values instead of instantaneous values.

Fig. 19.48

Let  $V_R$ ,  $V_Y$  and  $V_B$  be the r.m.s. values of the three phase voltages and  $I_R$ ,  $I_Y$  and  $I_B$  the r.m.s. values of the currents. Since these voltages and currents are assumed sinusoidal, they can be represented by vectors, the currents lagging behind their respective phase voltages by  $\phi$ .

Current through wattmeter  $W_1$  [Fig. 19.47 (b)] is  $I_R$

P.D. across voltage coil of  $W_1$  is

$$V_{RB} = V_R - V_B \quad \dots \text{vectorially}$$

This  $V_{RB}$  is found by compounding  $V_R$  and  $V_B$  reversed as shown in Fig. 19.42. It is seen that phase difference between  $V_{RB}$  and  $I_R = (30^\circ - \phi)$ .

$$\therefore \text{Reading of } W_1 = I_R V_{RB} \cos (30^\circ - \phi)$$

Similarly, as seen from Fig. 19.47 (b). Current through  $W_2 = I_Y$

$$\text{P.D. across } W_2 = V_{YB} = V_Y - V_B \quad \dots \text{vectorially}$$

Again,  $V_{YB}$  is found by compounding  $V_Y$  and  $V_B$  reversed as shown in Fig. 19.48. The angle between  $I_Y$  and  $V_{YB}$  is  $(30^\circ + \phi)$ . Reading of  $W_2 = I_Y V_{YB} \cos (30^\circ + \phi)$

Since load is balanced,  $V_{RB} = V_{YB} = \text{line voltage } V_L$ ;  $I_Y = I_R = \text{line current, } I_L$

$$\therefore W_1 = V_L I_L \cos (30^\circ - \phi) \text{ and } W_2 = V_L I_L \cos (30^\circ + \phi)$$

$$\therefore W_1 + W_2 = V_L I_L \cos (30^\circ - \phi) + V_L I_L \cos (30^\circ + \phi)$$

$$= V_L I_L [\cos 30^\circ \cos \phi + \sin 30^\circ \sin \phi + \cos 30^\circ \cos \phi - \sin 30^\circ \sin \phi]$$

$$= V_L I_L (2 \cos 30^\circ \cos \phi) = \sqrt{3} V_L I_L \cos \phi = \text{total power in the 3-phase load}$$

**Hence, the sum of the two wattmeter readings gives the total power consumption in the 3-phase load.**

It should be noted that phase sequence of  $RYB$  has been assumed in the above discussion. Reversal of phase sequence will interchange the readings of the two wattmeters.

### 19.19. Variations in Wattmeter Readings

It has been shown above that for a lagging power factor

$$W_1 = V_L I_L \cos (30^\circ - \phi) \text{ and } W_2 = V_L I_L \cos (30^\circ + \phi)$$

From this it is clear that individual readings of the wattmeters not only depend **on the load but upon its power factor also**. We will consider the following cases:

(a) When  $\phi = 0$  i.e. power factor is unity (i.e. resistive load) then,

$$W_1 = W_2 = V_L I_L \cos 30^\circ$$

Both wattmeters indicate equal and positive i.e. up-scale readings.

(b) When  $\phi = 60^\circ$  i.e. power factor = 0.5 (lagging)

Then  $W_2 = V_L I_L \cos (30^\circ + 60^\circ) = 0$ . Hence, the power is measured by  $W_1$  alone.

(c) When  $90^\circ > \phi > 60^\circ$  i.e.  $0.5 > \text{p.f.} > 0$ , then  $W_1$  is still positive but reading of  $W_2$  is reversed because the phase angle between the current and voltage is more than  $90^\circ$ . For getting the total power, the reading of  $W_2$  is to be subtracted from that of  $W_1$ .

Under this condition,  $W_2$  will read 'down scale' i.e. backwards. Hence, to obtain a reading on  $W_2$  it is necessary

$\phi$	$0^\circ$	$60^\circ$	$90^\circ$
$\cos \phi$	1	0.5	0
$W_1$	+ve	+ve	+ve
$W_2$	+ve	0	-ve
	$W_1 = W_2$		$W_1 = W_2$

to reverse either its pressure coil or current coil, usually the

*All readings taken after reversal of pressure coil are to be taken as negative.*

(d) When  $\phi = 90^\circ$  (i.e. pure inductive or capacitive load), then

$$W_1 = V_L I_L \cos(30^\circ - 90^\circ) = V_L I_L \sin 30^\circ;$$

$$W_2 = V_L I_L \cos(30^\circ + 90^\circ) = -V_L I_L \sin 30^\circ$$

As seen, the two readings are equal but of opposite sign.

$$\therefore W_1 + W_2 = 0$$

The above facts have been summarised in the above table for a lagging power factor.

### 19.20. Leading Power Factor\*

In the above discussion, lagging angles are taken positive. Now, we will see how wattmeter readings are changed if the power factor becomes leading. For  $\phi = +60^\circ$  (lag),  $W_2$  is zero. But for  $\phi = -60^\circ$  (lead),  $W_1$  is zero. So we find that for angles of lead, the reading of the two wattmeters are interchanged. Hence, for a *leading* power factor.

$$W_1 = V_L I_L \cos(30^\circ + \phi) \quad \text{and} \quad W_2 = V_L I_L \cos(30^\circ - \phi)$$

### 19.21. Power Factor–Balanced Load

In case the load is balanced (and currents and voltages are sinusoidal) and for a *lagging* power factor:

$$W_1 + W_2 = V_L I_L \cos(30^\circ - \phi) + V_L I_L \cos(30^\circ + \phi) = \sqrt{3} V_L I_L \cos \phi \quad \dots (i)$$

$$\text{Similarly } W_1 - W_2 = V_L I_L \cos(30^\circ - \phi) - V_L I_L \cos(30^\circ + \phi)$$

$$= V_L I_L (2 \times \sin \phi \times 1/2) = V_L I_L \sin \phi \quad \dots (ii)$$

$$\text{Dividing (ii) by (i), we have } \tan \phi = \frac{\sqrt{3}(W_1 - W_2)}{(W_1 + W_2)} \quad \dots (iii)$$

Knowing  $\tan \phi$  and hence  $\phi$ , the value of power factor  $\cos \phi$  can be found by consulting the trigonometrical tables. It should, however, be kept in mind that if  $W_2$  reading has been taken after reversing the pressure coil i.e. if  $W_2$  is negative, then the above relation becomes

$$\tan \phi = -\sqrt{3} \left( \frac{W_1 - W_2}{W_1 + W_2} \right) \quad \dots \text{ Art 19.22}$$

$$\tan \phi = \sqrt{3} \frac{W_1 - (-W_2)}{W_1 + (-W_2)} = \sqrt{3} \frac{W_1 + W_2}{W_1 - W_2}$$

Obviously, in this expression, only *numerical* values of  $W_1$  and  $W_2$  should be substituted. We may express power factor in terms of the ratio of the two wattmeters as under:

$$\text{Let } \frac{\text{smaller reading}}{\text{larger reading}} = \frac{W_2}{W_1} = r$$

\* For a leading p.f., conditions are just the opposite of this. In that case,  $W_1$  reads negative (Art. 19.22).

\*\* For a leading power factor, this expression becomes

$$\tan \phi = -\sqrt{3} \left( \frac{W_1 - W_2}{W_1 + W_2} \right) \quad \dots \text{ Art 19.22}$$

Fig. 19.49

If  $r$  is plotted against  $\cos \phi$ , then a curve called watt-ratio curve is obtained as shown in Fig. 19.49.

Then from equation (iii) above,

$$\tan \phi = \frac{\sqrt{3}[1 - (W_2 / W_1)]}{1 + (W_2 / W_1)} = \frac{\sqrt{3}(1-r)}{1+r}$$

$$\text{Now } \sec^2 \phi = 1 + \tan^2 \phi$$

$$\text{or } \frac{1}{\cos^2 \phi} = 1 + \tan^2 \phi$$

$$\therefore \cos \phi = \frac{1}{\sqrt{1 + \tan^2 \phi}}$$

$$= \frac{1}{\sqrt{1 + 3 \left( \frac{1-r}{1+r} \right)^2}}$$

$$= \frac{1+r}{2\sqrt{1-r+r^2}}$$

### 19.22. Balanced Load – leading power factor

In this case, as seen from Fig. 19.50

$$W_1 = V_L I_L \cos(30 + \phi)$$

$$\text{and } W_2 = V_L I_L \cos(30 - \phi)$$

$$\therefore W_1 + W_2 = \sqrt{3} V_L I_L \cos \phi - \text{as found above}$$

$$W_1 - W_2 = -V_L I_L \sin \phi$$

$$\therefore \tan \phi = -\frac{\sqrt{3}(W_1 - W_2)}{(W_1 + W_2)}$$

Fig. 19.50

Obviously, if  $\phi > 60^\circ$ , then phase angle between  $V_{RB}$  and  $I_R$  becomes more than  $90^\circ$ . Hence,  $W_1$  reads 'down-scale' *i.e.* it indicates negative reading. However,  $W_2$  gives positive reading even in the extreme case when  $\phi = 90^\circ$ .

### 19.23. Reactive Voltamperes with Two Wattmeters

$$\text{We have seen that } \tan \phi = \frac{\sqrt{3}(W_1 - W_2)}{(W_1 + W_2)}$$

Since the tangent of the angle of lag between phase current and phase voltage of a circuit is always equal to the ratio of the reactive power to the active power (in watts), it is clear that  $\sqrt{3}(W_1 - W_2)$  represents the reactive power (Fig. 19.51). Hence, for a balanced load, the reactive power is given by  $\sqrt{3}$  times the difference of the readings of the two wattmeters used to measure the power for a 3-phase circuit by the two wattmeter method. It may also be proved mathematically as follows:

Fig. 19.51

$$\begin{aligned}
 &= \sqrt{3}(W_1 - W_2) = \sqrt{3}[V_L I_L \cos(30^\circ - \phi) - V_L I_L \cos(30^\circ + \phi)] \\
 &= \sqrt{3}V_L I_L (\cos 30^\circ \cos \phi + \sin 30^\circ \sin \phi - \cos 30^\circ \cos \phi + \sin 30^\circ \sin \phi) \\
 &= \sqrt{3}V_L I_L \sin \phi
 \end{aligned}$$

### 19.24. Reactive Voltamperes with One Wattmeter

For this purpose, the wattmeter is connected as shown in Fig. 19.52 (a) and (b). The pressure coil is connected across Y and B lines whereas the current coil is included in the R line. In Fig.

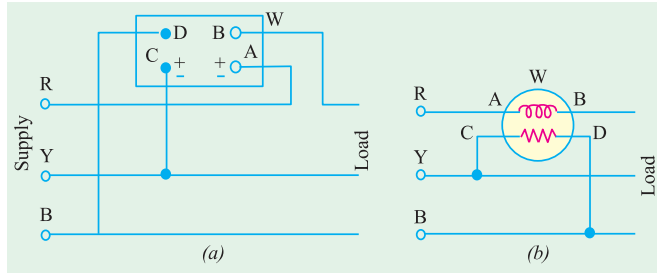

Fig. 19.52

19.48 (a), the current coil is connected between terminals A and B whereas pressure coil is connected between terminals C and D. Obviously, current flowing through the wattmeter is  $I_R$  and p.d. is  $V_{YB}$ . The angle between the two, as seen from vector diagram of Fig. 19.48, is  $(30 + 30 + 30 - \phi) = (90 - \phi)$

Hence, reading of the wattmeter is  $W = V_{YB} I_R \cos(90 - \phi) = V_{YB} I_R \sin \phi$

For a balanced load,  $V_{YB}$  equals the line voltage  $V_L$  and  $I_R$  equals the line current  $I_L$ , hence

$$W = V_L I_L \sin \phi$$

We know that the total reactive voltamperes of the load are  $Q = \sqrt{3}V_L I_L \sin \phi$ .

Hence, to obtain total VARs, the wattmeter reading must be multiplied by a factor of  $\sqrt{3}$ .

### 19.25. One Wattmeter Method

In this case, it is possible to apply two-wattmeter method by means of one wattmeter without breaking the circuit. The current coil is connected in any one line and the pressure coil is

Fig. 19.53

connected alternately between this and the other two lines (Fig. 19.53). The two readings so obtained, for a balanced load, correspond to those obtained by normal two wattmeter method. It should be kept in mind that this method is not of as much universal application as the two wattmeter method because it is restricted to fairly balanced loads only. However, it may be conveniently applied, for instance, when it is desired to find the power input to a factory motor in order to check the load upon the motor.

It may be pointed out here that the two wattmeters used in the two-wattmeter method (Art. 19.17) are usually combined into a single instrument in the case of switchboard wattmeter which is then known as a polyphase wattmeter. The combination is affected by arranging the two sets of coils in such a way as to operate on a single moving system resulting in an indication of the total power on the scale.

### 19.26. Copper Required for Transmitting Power under Fixed Conditions

The comparison between 3-phase and single-phase systems will be done on the basis of a fixed amount of power transmitted to a fixed distance with the same amount of loss and at the same maximum voltage between conductors. In both cases, the weight of copper will be directly

proportional to the number of wires (since the distance is fixed) and inversely proportional to the resistance of each wire. We will assume the same power factor and same voltage.

where

$$P_1 = VI_1 \cos \phi \text{ and } P_3 = \sqrt{3}VI_3 \cos \phi$$

$$I_1 = \text{r.m.s. value of current in 1-phase system}$$

$$I_3 = \text{r.m.s. value of line current in 3-phase system}$$

$$P_1 = P_2 \therefore VI_1 \cos \phi = \sqrt{3}VI_3 \cos \phi \therefore I_1 = \sqrt{3}I_3$$

also  $I_1^2 R_1 \times 2 = I_3^2 R_3 \times 3$  or  $\frac{R_1}{R_3} = \frac{3I_3^2}{2I_1^2}$

Substituting the value of  $I_1$ , we get  $\frac{R_1}{R_3} = \frac{3I_3^2}{3I_3^2 \times 2} = \frac{1}{2}$

$\therefore \frac{\text{copper 3-phase}}{\text{copper 1-phase}} = \frac{\text{No. of wires 3-phase}}{\text{No. of wires 1-phase}} \times \frac{R_1}{R_3} = \frac{3}{2} \times \frac{1}{2} = \frac{3}{4}$

Hence, we find that for transmitting the same amount of power over a fixed distance with a fixed line loss, we need only three-fourths of the amount of copper that would be required for a single phase or to put it in another way, one-third more copper is required for a 1-phase system than would be necessary for a three-phase system.

**Example 19.38.** Phase voltage and current of a star-connected inductive load is 150 V and 25 A. Power factor of load is 0.707 (lag). Assuming that the system is 3-wire and power is measured using two wattmeters, find the readings of wattmeters.

(Elect. Instrument & Measurements, Nagpur Univ. 1993)

**Solution.**  $V_{ph} = 150\text{V}; V_L = 150 \sqrt{3}\text{V}; I_{ph} = I_L = 25 \text{ A}$

Total power =  $\sqrt{3} V_L I_L \cos \phi = \sqrt{3} \times 150 \times \sqrt{3} \times 25 \times 0.707 = 7954 \text{ W}$

$\therefore W_1 + W_2 = 7954 \text{ W} \dots (i)$

$\cos \phi = 0.707; \phi = \cos^{-1}(0.707) = 45^\circ; \tan 45^\circ = 1$

Now, for a lagging power factor,  $\tan \phi = \sqrt{3} (W_1 - W_2) / (W_1 + W_2)$  or  $1 = \sqrt{3} (W_1 - W_2) / 7954$

$\therefore (W_1 - W_2) = 4592 \text{ W} \dots (ii)$

From (i) and (ii) above, we get,  $W_1 = 6273 \text{ W}; W_2 = 1681 \text{ W}.$

**Example 19.39.** In a balanced 3-phase 400-V circuit, the line current is 115.5 A. When power is measured by two wattmeter method, one meter reads 40 kW and the other zero. What is the power factor of the load? If the power factor were unity and the line current the same, what would be the reading of each wattmeter?

**Solution.** Since  $W_2 = 0$ , the whole power is measured by  $W_1$ . As per Art. 19.18, in such a situation, p.f. = 0.5. However, it can be calculated as under.

Since total power is 40 kW,  $\therefore 40,000 = \sqrt{3} \times 400 \times 115.5 \cos \phi$ ;  $\cos \phi = 0.5$

If the power factor is unity with line currents remaining the same, we have

$$\tan \phi = \frac{\sqrt{3}(W_1 - W_2)}{(W_1 + W_2)} = 0 \text{ or } W_1 = W_2$$

Also,  $(W_1 + W_2) = \sqrt{3} \times 400 \times 115.5 \times 1 = 80000 \text{ W} = 80 \text{ kW}$

As per Art. 19.19, at unity p.f.,  $W_1 = W_2$ . Hence, each wattmeter reads =  $80/2 = 40 \text{ kW}.$

**Example 19.40.** The input power to a three-phase motor was measured by two wattmeter method. The readings were 10.4 KW and - 3.4 KW and the voltage was 400 V. Calculate (a) the power factor (b) the line current.

(Elect. Engg. A.M.Ae, S.I. June 1991)

**Solution.** As given in Art. 19.21, when  $W_2$  reads negative, then we have

$\tan \phi = \sqrt{3}(W_1 + W_2) / (W_1 - W_2)$ . Substituting numerical values of  $W_1$  and  $W_2$ , we get

$$\tan \phi = \sqrt{3}(10.4 + 3.4) / (10.4 - 3.4) = 1.97; \phi = \tan^{-1}(1.97) = 63.1^\circ$$

$$(a) \text{ p.f.} = \cos \phi = \cos 63.1^\circ = \mathbf{0.45 \text{ (lag)}}$$

$$(b) W = 10.4 - 3.4 = 7 \text{ KW} = 7,000 \text{ W}$$

$$7000 = \sqrt{3}I_L \times 400 \times 0.45; I_L = \mathbf{22.4 \text{ A}}$$

**Example 19.41.** A three-phase, three-wire, 100-V, ABC system supplies a balanced delta connected load with impedance of  $20 \angle 45^\circ$  ohm.

(a) Determine the phase and line currents and draw the phase or diagram (b) Find the wattmeter readings when the two wattmeter method is applied to the system.

(Elect. Machines, A.M.I.E. Sec B.)

**Solution.** (a) The phasor diagram is shown in Fig. 19.54 (b).

Let  $V_{AB} = 100 \angle 0^\circ$ . Since phase sequence is ABC,  $V_{BC} = 100 \angle -120^\circ$  and  $V_{CA} = 100 \angle 120^\circ$

$$\text{Phase current } I_{AB} = \frac{V_{AB}}{Z_{AB}} = \frac{100 \angle 0^\circ}{20 \angle 45^\circ} = 5 \angle -45^\circ$$

$$I_{BC} = \frac{V_{BC}}{Z_{BC}} = \frac{100 \angle -120^\circ}{20 \angle 45^\circ} = 5 \angle -165^\circ, I_{CA} = \frac{V_{CA}}{Z_{CA}} = \frac{100 \angle 120^\circ}{20 \angle 45^\circ} = 5 \angle 75^\circ$$

Fig. 19.54

Applying KCL to junction A, we have

$$I_A + I_{CA} - I_{AB} = 0 \text{ or } I_A = I_{AB} - I_{CA}$$

$$\therefore \text{Line current } I_A = 5 \angle -45^\circ - 5 \angle 75^\circ = 8.66 \angle -75^\circ$$

Since the system is balanced,  $I_B$  will lag  $I_A$  by  $120^\circ$  and  $I_C$  will lag  $I_A$  by  $240^\circ$ .

$$\therefore I_B = 8.66 \angle (75^\circ - 120^\circ) = 8.66 \angle -45^\circ; I_C = 8.66 \angle (-75^\circ - 240^\circ) = 8.66 \angle -315^\circ = 8.66 \angle 45^\circ$$

(b) As shown in Fig. 19.54 (b), reading of wattmeter  $W_1$  is  $W_1 = V_{AC} I_C \cos \phi$ . Phasor  $V_{AC}$  is the reverse of phasor  $V_{CA}$ . Hence,  $V_{AC}$  is the reverse of phasor  $V_{CA}$ . Hence,  $V_{AC}$  lags the reference vector by  $60^\circ$  whereas  $I_A$  lags by  $75^\circ$ . Hence, phase difference between the two is  $(75^\circ - 60^\circ) = 15^\circ$

$$\therefore W_1 = 100 \times 8.66 \times \cos 15^\circ = 836.5 \text{ W}$$

$$\text{Similarly } W_2 = V_{BC} I_B \cos \phi = 100 \times 8.66 \times \cos 75^\circ = 224.1 \text{ W}$$

$$\therefore W_1 + W_2 = 836.5 + 224.1 = 1060.6 \text{ W}$$

Resistance of each delta branch =  $20 \cos 45^\circ = 14.14 \Omega$

Total power consumed =  $3 I^2 R = 3 \times 5^2 \times 14.14 = 1060.6 \text{ W}$

Hence, it proves that the sum of the two wattmeter readings gives the total power consumed.

**Example 19.42.** A 3-phase, 500-V motor load has a power factor of 0.4. Two wattmeters connected to measure the power show the input to be 30 kW. Find the reading on each instrument.

(Electrical Meas., Nagpur Univ. 1991)

**Solution.** As seen from Art. 19.21

$$\tan \phi = \frac{\sqrt{3}(W_1 - W_2)}{W_1 + W_2} \quad \dots (i)$$

Now,  $\cos \phi = 0.4$ ;  $\phi = \cos^{-1}(0.4) = 66.6^\circ$ ;  $\tan 66.6^\circ = 2.311$

$$W_1 + W_2 = 30 \quad \dots (ii)$$

Substituting these values in equation (i) above, we get

$$2.311 = \frac{\sqrt{3}(W_1 - W_2)}{30} \quad \therefore W_1 - W_2 = 40 \quad \dots (iii)$$

From Eq. (ii) and (iii), we have  $W_1 = 45 \text{ kW}$  and  $W_2 = -5 \text{ kW}$

Since  $W_2$  comes out to be negative, second wattmeter reads 'down scale'. Even otherwise it is obvious that p.f. being less than 0.5,  $W_2$  must be negative (Art. 19.19)

**Example 19.43.** The power in a 3-phase circuit is measured by two wattmeters. If the total power is 100 kW and power factor is 0.66 leading, what will be the reading of each wattmeter? Give the connection diagram for the wattmeter circuit. For what p.f. will one of the wattmeter read zero?

**Solution.**  $\phi = \cos^{-1}(0.66) = 48.7^\circ$ ;  $\tan \phi = 1.1383$

Since p.f. is leading,

$$\therefore \tan \phi = -\frac{\sqrt{3}(W_1 - W_2)}{W_1 + W_2} \quad \therefore 1.1383 = \sqrt{3}(W_1 - W_2)/100$$

$$\therefore W_1 - W_2 = -65.7 \text{ and } W_1 + W_2 = 100 \quad \therefore W_1 = 17.14 \text{ kW}; W_2 = 82.85 \text{ kW}$$

Connection diagram is similar to that shown in Fig. 19.47 (b). One of the wattmeters will read zero when p.f. = 0.5

**Example 19.44.** Two wattmeters are used for measuring the power input and the power factor of an over-excited synchronous motor. If the readings of the meters are (-2.0 kW) and (+7.0 kW) respectively, calculate the input and power factor of the motor.

(Elect. Technology, Punjab Univ., June, 1991)

**Solution.** Since an over-excited synchronous motor runs with a leading p.f., we should use the relationship derived in Art. 19.22.

$$\tan \phi = \frac{\sqrt{3}(W_1 - W_2)}{W_1 + W_2}$$

Moreover, as explained in the same article, it is  $W_1$  that gives negative reading and not  $W_2$ .

Hence,

$$W_1 = -2 \text{ kW}$$

$$\therefore \tan \phi = -\frac{\sqrt{3}(-2-7)}{-2+7} = \sqrt{3} \times \frac{9}{5} = 3.1176$$

$$\therefore \phi = \tan^{-1}(3.1176) = 71.2^\circ \text{ (lead)}$$

$$\therefore \cos \phi = \cos 71.2^\circ = 0.3057 \text{ (lead) and}$$

$$\text{Input} = W_1 + W_2 = -2 + 7 = 5 \text{ kW}$$

**Example 19.45.** A 440-V, 3-phase, delta-connected induction motor has an output of 14.92 kW at a p.f. of 0.82 and efficiency 85%. Calculate the readings on each of the two wattmeters connected to measure the input. Prove any formula used.

If another star-connected load of 10 kW at 0.85 p.f. lagging is added in parallel to the motor, what will be the current draw from the line and the power taken from the line?

Fig. 19.55

(Elect. Technology-I, Bombay Univ.)

**Solution.** Motor input =  $14,920/0.85 = 17,600 \text{ W} \therefore W_1 + W_2 = 17.6 \text{ kW} \dots (i)$

$$\cos \phi = 0.82; \phi = 34.9^\circ, \tan 34.9^\circ = 0.6976; 0.6976 = \sqrt{3} \frac{W_1 - W_2}{17.6}$$

$$\therefore W_1 - W_2 = 7.09 \text{ kW} \dots (ii)$$

From (i) and (ii) above, we get  $W_1 = 12.35 \text{ kW}$  and  $W_2 = 5.26 \text{ kW}$

$$\text{Motor kVA, } S_m = \frac{\text{motor kW}}{\cos \phi_m} = \frac{17.6}{0.82} = 21.46 \therefore S_m = 21.46 \angle -34.9^\circ = (17.6 - j12.28) \text{ kVA}$$

$$\text{Load p.f.} = 0.85 \therefore \phi = \cos^{-1}(0.85) = 31.8^\circ; \text{ Load kVA, } S_Y = 10/0.85 = 11.76$$

$$\therefore S_Y = 11.76 \angle -31.8^\circ = (10 - j6.2) \text{ kVA}$$

$$\text{Combined kVA, } S = S_m + S_Y = (27.6 - j18.48) = 32.2 \angle -33.8^\circ \text{ kVA}$$

$$I = \frac{S}{\sqrt{3} \cdot V} = \frac{33.2 \times 10^3}{\sqrt{3} \times 440} = 43.56 \text{ A}$$

$$\text{Power taken} = 27.6 \text{ kW}$$

**Example 19.46.** The power input to a synchronous motor is measured by two wattmeters both of which indicate 50 kW. If the power factor of the motor be changed to 0.866 leading, determine the readings of the two wattmeters, the total input power remaining the same. Draw the vector diagram for the second condition of the load. (Elect. Technology, Nagpur Univ. 1992)

**Solution.** In the first case both wattmeters read equal and positive. Hence motor must be running at unity power (Art. 19.22).

**When p.f. is 0.866 leading**

$$\text{In this case; } W_1 = V_L I_L \cos(30^\circ + \phi);$$

$$W_2 = V_L I_L \cos(30^\circ - \phi)$$

$$\therefore W_1 + W_2 = \sqrt{3} V_L I_L \cos \phi$$

$$W_1 - W_2 = -V_L I_L \sin \phi$$

$$\therefore \tan \phi = \frac{\sqrt{3}(W_1 - W_2)}{(W_1 + W_2)}$$

$$\phi = \cos^{-1}(0.866) = 30^\circ$$

$$\tan \phi = 1/\sqrt{3}$$

$$\therefore \frac{1}{\sqrt{3}} = \frac{-\sqrt{3}(W_1 - W_2)}{100}$$

$$\therefore W_1 - W_2 = -100/3$$

$$\text{and } W_1 + W_2 = 100$$

$$\therefore 2W_1 = 200/3; W_1 = 33.33 \text{ kW}; W_2 = 66.67 \text{ kW}$$

For connection diagram, please refer to Fig. 19.47. The vector or phasor diagram is shown in Fig. 19.56.

Fig. 19.56

**Example 19.47 (a).** A star-connected balanced load is supplied from a 3- $\phi$  balanced supply with a line voltage of 416 volts at a frequency of 50 Hz. Each phase of the load consists of a resistance and a capacitor joined in series and the reading on two wattmeters connected to measure the total power supplied are 782 W and 1980 W, both positive. Calculate

(i) power factor of circuit, (ii) the line current, (iii) the capacitance of each capacitor.

(Elect. Engg. I, Nagpur Univ. 1993)

**Solution. (i)** As seen from Art. 19.21  $\tan \phi = -\frac{\sqrt{3}(W_1 - W_2)}{(W_1 + W_2)} = -\frac{\sqrt{3}(782 - 1980)}{(782 + 1980)} = 0.75$ ;  
 $\phi = 36.9^\circ$ ,  $\cos \phi = 0.8$

$$(ii) \sqrt{3} \times 416 \times I_L \times 0.8 = 2762, I_L = 4.8 \text{ A}$$

$$(iii) Z_{ph} = V_{ph} / I_{ph} = (416\sqrt{3}) / 4.8 = 50\Omega, X_C = Z_{ph} \sin \phi = 50 \times 0.6 = 30\Omega$$

$$\text{Now, } X_C = 1 / 2\pi fC = 1 / 2\phi \times 50 \times C = 106 \times 10^{-6} \text{ F}$$

**Example 19.48.** Each phase of a 3-phase,  $\Delta$ -connected load consists of an impedance  $Z = 20 \angle 60^\circ$  ohm. The line voltage is 440 V at 50 Hz. Compute the power consumed by each phase impedance and the total power. What will be the readings of the two wattmeters connected?

(Elect. and Mech. Technology, Osmania Univ.)

$$\text{Solution. } Z_{ph} = 20\Omega; V_{ph} = V_L = 440\text{V}; I_{ph} = V_{ph} / Z_{ph} = 440/20 = 22 \text{ A}$$

$$\text{Since } \phi = 60^\circ; \cos \phi = \cos 60^\circ = 0.5; R_{ph} = Z_{ph} \times \cos 60^\circ = 20 \times 0.5 = 10\Omega$$

$$\therefore \text{Power/phase} = I_{ph}^2 R_{ph} = 22^2 \times 10 = \mathbf{4,840 \text{ W}}$$

$$\text{Total power} = 3 \times 4,840 = \mathbf{14,520 \text{ W}}$$
 [or  $P = \sqrt{3} \times 440 \times (\sqrt{3} \times 22) \times 0.5 = 14,520 \text{ W}$ ]

$$\text{Now, } W_1 + W_2 = 14,520.$$

$$\text{Also } \tan \phi = \sqrt{3} \frac{W_1 - W_2}{W_1 + W_2} \quad \therefore \tan 60^\circ = \sqrt{3} = \sqrt{3} \frac{W_1 - W_2}{14,520}$$

$$\therefore W_1 - W_2 = 14,520. \text{ Obviously, } W_2 = 0$$

Even otherwise it is obvious that  $W_2$  should be zero because p.f. =  $\cos 60^\circ = 0.5$  (Art. 19.19).

**Example 19.49.** Three identical coils, each having a reactance of  $20 \Omega$  and resistance of  $20 \Omega$  are connected in (a) star (b) delta across a 440-V, 3-phase line. Calculate for each method of connection the line current and readings on each of the two wattmeters connected to measure the power.

(Electro-mechanics, Allahabad Univ. 1992)

**Solution. (a) Star Connection**

$$Z_{ph} = \sqrt{20^2 + 20^2} = 20\sqrt{2} = 28.3\Omega; V_{ph} = 440 / \sqrt{3} = 254 \text{ V}$$

$$I_{ph} = 254 / 28.3 = 8.97 \text{ A}; I_L = \mathbf{8.97 \text{ A}}; \cos \phi = R_{ph} / Z_{ph} = 20/28.3 = 0.707$$

$$\text{Total power taken} = \sqrt{3} V_L I_L \cos \phi = \sqrt{3} \times 440 \times 8.97 \times 0.707 = 4830 \text{ W}$$

$$\text{If } W_1 \text{ and } W_2 \text{ are wattmeter readings, then } W_1 + W_2 = 4830 \text{ W} \quad \dots (i)$$

$$\text{Now, } \tan \phi = 20 / 20 = \sqrt{3} (W_1 - W_2) / (W_1 + W_2); (W_1 - W_2) = 2790 \text{ W} \quad \dots (ii)$$

$$\text{From (i) and (ii) above, } W_1 = \mathbf{3810 \text{ W}}; W_2 = \mathbf{1020 \text{ W}}$$

**(b) Delta Connection**

$$Z_{ph} = 28.3\Omega, V_{ph} = 440 \text{ V}, I_{ph} = 440 / 28.3 = 15.5 \text{ A}; I_L = 15.5 \times \sqrt{3} = 26.8 \text{ A}$$

$$P = \sqrt{3} \times 440 \times 26.8 \times 0.707 = 14,490 \text{ W} \quad (\text{it is 3 times the Y-power})$$

$$\therefore W_1 + W_2 = 14,490 \text{ W} \quad \dots (iii)$$

$$\tan \phi = 20 / 20 = \sqrt{3} (W_1 - W_2) / 14,490; W_1 - W_2 = 8370 \quad \dots (iv)$$

$$\text{From Eq. (iii) and (iv), we get, } W_1 = \mathbf{11,430 \text{ W}}; W_2 = \mathbf{3060 \text{ W}}$$

**Note:** These readings are 3-times the Y-readings.

**Example 19.50.** Three identical coils are connected in star to a 200-V, three-phase supply and each takes 500 W. The power factor is 0.8 lagging. What will be the current and the total power if the same coils are connected in delta to the same supply? If the power is measured by two wattmeters, what will be their readings? Prove any formula used.

(Elect. Engg. A.M. A. S.I. Dec. 1991)

**Solution.** When connected in star as shown in Fig. 19.57 (a),  $V_{ph} = 200/\sqrt{3} = 115.5 \text{ V}$

Now,  $V_{ph} I_{ph} \cos \phi = \text{power per phase or } 115.5 \times I_{ph} \times 0.8 = 500$

$$\therefore I_{ph} = 5.41 \text{ A}; Z_{ph} = V_{ph} / I_{ph} = 115.5 / 5.41 = 21.34 \Omega$$

$$R = Z_{ph} \cos \phi = 21.34 \times 0.8 = 17 \Omega; X_L = Z_{ph} \sin \phi = 21.34 \times 0.6 = 12.8 \Omega$$

Fig. 19.57

The same three coils have been connected in delta in Fig. 19.57 (b). Here,  $V_{ph} = V_L = 200 \text{ V}$ .

$$I_{ph} = 200 / 21.34 = 9.37 \text{ A}; I_L = \sqrt{3} I_{ph} = 9.37 \times 1.732 = \mathbf{16.23 \text{ A}}$$

Total power consumed =  $\sqrt{3} \times 200 \times 16.23 \times 0.8 = \mathbf{4500 \text{ W}}$

It would be seen that when the same coils are connected in delta, they consume three times more power than when connected in star.

#### Wattmeter Readings

$$\text{Now, } W_1 + W_2 = 4500; \tan \phi = \frac{\sqrt{3}(W_1 - W_2)}{(W_1 + W_2)}$$

$$\phi = \cos^{-1}(0.8) = 36.87^\circ; \tan \phi = 0.75$$

$$0.75 = \frac{\sqrt{3}(W_1 - W_2)}{4500} \therefore (W_1 - W_2) = 1950 \text{ W}$$

$$\therefore W_1 = (4500 + 1950)/2 = 3225 \text{ W}; W_2 = \mathbf{1275 \text{ W}}$$

**Example 19.51.** A 3-phase, 3-wire, 415-V system supplies a balanced load of 20 A at a power factor 0.8 lag. The current coil of wattmeter 1 is in phase R and of wattmeter 2 in phase B. Calculate (i) the reading on 1 when its voltage coil is across R and Y (ii) the reading on 2 when its voltage coil is across B and Y and (iii) the reading on 1 when its voltage coil is across Y and B. Justify your answer with relevant phasor diagram. (Elect. Machines, A.M.I.E. Sec. B, 1991)

**Solution.** (i) As seen from phasor diagram of Fig. 19.57 (a)

Fig. 19.57 (a)

$$W_1 = V_{RY} I_A \cos(30 + \phi) = \sqrt{3} \times 415 \times 20 \times \cos(36.87^\circ + 30^\circ) = 5647 \text{ W}$$

(ii) Similarly,  $W_2 = V_{BY} I_B \cos(30 - \phi)$

It should be noted that voltage across  $W_2$  is  $V_{BY}$  and not  $V_{YB}$ . Moreover,  $\phi = \cos^{-1}(0.8) = 36.87^\circ$ ,

$$\therefore W_2 = \sqrt{3} \times 415 \times 20 \times \cos(30^\circ - 36.87^\circ) = 14,275 \text{ W}$$

(iii) Now, phase angle between  $I_R$  and  $V_{YB}$  is  $(90^\circ - \phi)$

$$\therefore W_2 = V_{YB} I_R \cos(90^\circ - \phi) = \sqrt{3} \times 415 \times 20 \times \sin 36.87^\circ = 8626 \text{ VAR}$$

**Example 19.52.** A wattmeter reads 5.54 kW when its current coil is connected in R phase and its voltage coil is connected between the neutral and the R phase of a symmetrical 3-phase system supplying a balanced load of 30 A at 400 V. What will be the reading on the instrument if the connections to the current coil remain unchanged and the voltage coil be connected between B and Y phases? Take phase sequence RYB. Draw the corresponding phasor diagram. (Elect. Machines, A.M.I.E., Sec. B, 1992)

Fig. 19.57 (b)

**Solution.** As seen from Fig. 19.57 (b).

$$W_1 = V_R I_R \cos \phi \text{ or } 5.54 \times 10^3 = (400 / \sqrt{3}) \times 30 \times \cos \phi; \therefore \cos \phi = 0.8, \sin \phi = 0.6$$

In the second case (Fig. 19.57 (b))

$$W_2 = V_{YB} I_R \cos(90^\circ - \phi) = 400 \times 30 \times \sin \phi = 400 \times 30 \times 0.6 = 7.2 \text{ kW}$$

**Example 19.53.** A 3-phase, 3-wire balanced load with a lagging power factor is supplied at 400 V (between lines). A 1-phase wattmeter (scaled in kW) when connected with its current coil in the R-line and voltage coil between R and Y lines gives a reading of 6 kW. When the same terminals of the voltage coil are switched over to Y and B-lines, the current-coil connections remaining the same, the reading of the wattmeter remains unchanged. Calculate the line current and power factor of the load. Phase sequence is  $R \rightarrow Y \rightarrow B$ . (Elect. Engg-1, Bombay Univ. 1985)

**Solution.** The current through the wattmeter is  $I_R$  and p.d. across its pressure coil is  $V_{RY}$ . As seen from the phasor diagram of Fig. 19.58, the angle between the two is  $(30^\circ + \phi)$ .

$$\therefore W_1 = V_{RY} I_R \cos(30^\circ + \phi) = V_L I_L \cos(30^\circ + \phi) \quad \dots (i)$$

In the second case, current is  $I_R$  but voltage is  $V_{YB}$ . The angle between the two is  $(90^\circ - \phi)$

$$\therefore W_2 = V_{YB} I_R \cos(90^\circ - \phi) = V_L I_L \cos(90^\circ - \phi)$$

Since  $W_1 = W_2$  we have

$$V_L I_L \cos(30^\circ + \phi) = V_L I_L \cos(90^\circ - \phi)$$

$$\therefore 30^\circ + \phi = 90^\circ - \phi$$

$$\text{or } 2\phi = 60^\circ \therefore \phi = 30^\circ$$

$$\therefore \text{load power factor} = \cos 30^\circ = 0.866 \text{ (lag)}$$

Now  $W_1 = W_2 = 6 \text{ kW}$ .

Hence, from (i) above, we get

$$6000 = 400 \times I_L \cos 60^\circ; I_L = 30 \text{ A}$$

Fig. 19.58

**Example 19.54.** A 3-phase, 400 V circuit supplies a  $\Delta$ -connected load having phase impedances of  $Z_{AB} = 25\angle 0^\circ$ ;  $Z_{BC} = 25\angle 30^\circ$  and  $Z_{CA} = 25\angle -30^\circ$ .

Two wattmeters are connected in the circuit to measure the load power. Determine the wattmeter readings if their current coils are in the lines (a) A and B; (b) B and C; and (c) C and A. The phase sequence is ABC. Draw the connections of the wattmeter for the above three cases and check the sum of the two wattmeter readings against total power consumed.

**Solution.** Taking  $V_{AB}$  as the reference voltage, we have  $Z_{AB} = 400\angle 0^\circ$ ;  $Z_{BC} = 400\angle -120^\circ$  and  $Z_{CA} = 400\angle 120^\circ$ .

The three phase currents can be found as follows:

$$I_{AB} = \frac{V_{AB}}{Z_{AB}} = \frac{400\angle 0^\circ}{25\angle 0^\circ} = 16\angle 0^\circ = (16 + j0)$$

$$I_{BC} = \frac{V_{BC}}{Z_{BC}} = \frac{400\angle -120^\circ}{25\angle 30^\circ} = 16\angle -150^\circ = (-13.8 - j8)$$

$$I_{CA} = \frac{V_{CA}}{Z_{CA}} = \frac{400\angle -120^\circ}{25\angle 30^\circ} = 16\angle -150^\circ = (-13.8 - j8)$$

Fig. 19.59

The line currents  $I_A$ ,  $I_B$  and  $I_C$  can be found by applying KCL at the three nodes A, B and C of the load.

$$I_A = I_{AB} + I_{AC} = I_{AB} - I_{CA} = (16 + j0) - (-13.8 + j8) = 29.8 - j8 = 30.8\angle -15^\circ$$

$$I_B = I_{BC} - I_{AB} = (-13.8 - j8) - (16 + j0) = -29.8 - j8 = 30.8\angle -165^\circ$$

$$I_C = I_{CA} - I_{BC} = (-13.8 + j8) - (-13.8 - j8) = 0 + j16 = 16\angle 90^\circ$$

The phasor diagram for line and phase currents is shown in Fig. 19.59 (a) and (b).

(a) As shown in Fig. 19.60 (a), the current coils of the wattmeters are in the line A and B and the voltage coil of  $W_1$  is across the lines A and C and that of  $W_2$  is across the lines B and C. Hence, current through  $W_1$  is  $I_A$  and voltage across it is  $V_{AC}$ . The power indicated by  $W_1$  may be found in the following two ways:

$$(i) P_1 = |V_{AC}| \cdot |I_A| \times (\text{cosine of the angle between } V_{AC} \text{ and } I_A) \\ = 400 \times 30.8 \times \cos(30^\circ + 15^\circ) = 8710 \text{ W}$$

(ii) We may use current conjugate (Art.) for finding the power

$$P_{VA} = V_{AC} \cdot I_A = -400\angle 120^\circ \times 30.8\angle 15^\circ$$

$$\therefore P_1 = \text{real part of } P_{VA} = -400 \times 30.8 \times \cos 135^\circ = 8710 \text{ W}$$

$$P_2 = \text{real part of } [V_{BC} Z_B] = 400\angle 120^\circ \times 30.8\angle -165^\circ$$

$$= 400 \times 30.8 \times \cos(-45^\circ) = 8710 \text{ W}$$

$$\therefore P_1 + P_2 = 8710 + 8710 = 17,420 \text{ W.}$$

Fig. 19.60

(b) As shown in Fig. 19.60 (b), the current coils of the wattmeters are in the lines B and C whereas voltage coil of  $W_1$  is across the lines B and A and that of  $W_2$  is across lines C and A.

$$(i) \therefore P_1 = |V_{BA}| \cdot |I_B| \cos(\text{angle between } V_{BA} \text{ and } I_B) \\ = 400 \times 30.8 \times \cos 15^\circ = 11,900 \text{ W}$$

(ii) Using voltage conjugate (which is more convenient in this case), we have

$$P_{VA} = V_{BA}^* \cdot I_B = -400 \angle 0^\circ \times 30.8 \angle -165^\circ \\ \therefore P_1 = \text{real part of } P_{VA} = -400 \times 30.8 \times \cos(-165^\circ) = 11,900 \text{ W} \\ P_2 = \text{real part of } [V_{CA}^* I_C] = [400 \angle -120^\circ \times 16 \angle 90^\circ] = 400 \times 16 \times \cos(-30^\circ) = 5,540 \text{ W.}$$

$$\therefore P_1 + P_2 = 11,900 + 5,540 = 17,440 \text{ W.}$$

(c) As shown in Fig. 19.60 (c), the current coils of the wattmeters are in the lines C and A whereas the voltage coil of  $W_1$  is across the lines C and B and that of  $W_2$  is across the lines A and B.

$$(i) P_1 = \text{real part of } [V_{CB}^* I_C] = [(400 \angle 120^\circ) (16 \angle 90^\circ)] \\ = 400 \times 16 \times \cos 210^\circ = 5,540 \text{ W}$$

$$P_2 = \text{real part of } [V_{AB}^* I_A] = [400 \angle 0^\circ \times 30.8 \angle -15^\circ] = 400 \times 30.8 \times \cos \angle -15^\circ = 11,900 \text{ W}$$

$$\therefore P_1 + P_2 = 5,540 + 11,900 = 17,440 \text{ W}$$

Total power consumed by the phase load can be found directly as under :-

$$\begin{aligned}
 P_T &= \text{real part of } [V_{AB}I_{AB}^* + V_{BC}I_{BC}^* + V_{CA}I_{CA}^*] \\
 &= \text{real part of} \\
 &\quad [(400\angle 0^\circ)(16\angle -0^\circ) + (400\angle -120^\circ)(16\angle 150^\circ) + (400\angle 120^\circ)(16\angle -150^\circ)] \\
 &= 400 \times 16 \times \text{real part of } (1\angle 0^\circ + 1\angle 30^\circ + 1\angle -30^\circ) \\
 &= 400 \times 16 (\cos 0^\circ + \cos^\circ + \cos(-30^\circ)) = 17,485 \text{ W}
 \end{aligned}$$

**Note.** The slight variation in the different answers is due to the approximation made.

**Example 19.55.** In a balanced 3-phase system load 1 draws 60 kW and 80 leading kVAR whereas load 2 draws 160 kW and 120 lagging kVAR. If line voltage of the supply is 1000 V, find the line current supplied by the generator. (Fig. 19.61)

**Solution.** For load 1 which is a leading load,  $\tan \phi_1 = Q_1 / P_1 = 80/60 = -1.333$ ;  $\phi_1 = 53.1^\circ$ ,  $\cos \phi_1 = 0.6$ . Hence, line current of this load is

$$I_1 = 60,000 / \sqrt{3} \times 1000 \times 0.6 = 57.8 \text{ A}$$

For load 2,  $\tan \phi_2 = 120/160 = 0.75$ ;  $\phi_2 = 26.9^\circ$ ,  $\cos \phi_2 = 0.8$ . The line current drawn by this load is

$$I_2 = 160,000 / \sqrt{3} \times 1000 \times 0.8 = 115.5 \text{ A}$$

If we take the phase voltage as the reference voltage i.e.  $V_{ph} = (1000 / \sqrt{3}) \angle 0^\circ = 578 \angle 0^\circ$ ; then  $I_1$  leads this voltage by  $53.1^\circ$  whereas  $I_2$  lags it by  $36.9^\circ$ . Hence,  $I_1 = 57.8 \angle 53.1^\circ$  and  $I_2 = 115.5 \angle -36.9^\circ$

$$\begin{aligned}
 \therefore I_{L1} &= I_1 + I_2 = 57.8 \angle 53.1^\circ + 115.5 \\
 &\quad \angle -36.9^\circ = 171.7 \angle 42.3^\circ \text{ A}
 \end{aligned}$$

**Example 19.56.** A single-phase motor drawing 10A at 0.707 lagging power factor is connected across lines R and Y of a 3-phase supply line connected to a 3-phase motor drawing 15A at a lagging power factor of 0.8 as shown in Fig. 19.62(a). Assuming RYB sequence, calculate the three line currents.

**Solution.** In the phasor diagram of Fig. 19.61 (b) are shown the three phase voltages and the one line voltage  $V_{RY}$  which is ahead of its phase voltage  $V_R$ . The current  $I_1$  drawn by single-phase motor lags  $V_{RY}$  by  $\cos^{-1} 0.707$  or  $45^\circ$ . It lags behind the reference voltage  $V_R$  by  $15^\circ$  as shown. Hence,  $I_1 = 10 \angle -15^\circ = 9.6 - j2.6 \text{ A}$ . The 3-phase motor currents lag behind their respective phase voltages by  $\cos^{-1} 0.8$  or  $36.9^\circ$ . Hence,  $I_{R1} = 15 \angle -36.9^\circ = 12 - j9$ .

$$I_{Y1} = 15 \angle (-120^\circ - 36.9^\circ) = 15 \angle -156.9^\circ = -13.8 - j5.9$$

$$I_B = 15 \angle (120^\circ - 36.9^\circ) = 15 \angle 83.1^\circ$$

Fig. 19.61

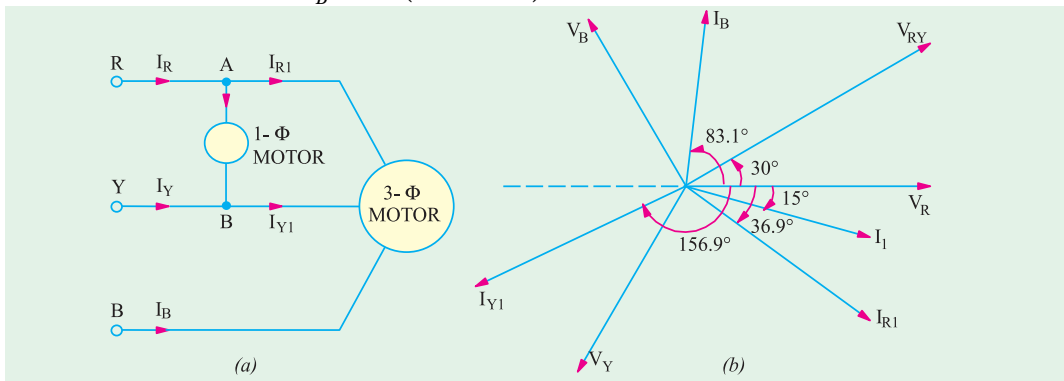

Fig. 19.62

Applying Kirchoff's laws to point A of Fig. 19.62 (a), we get

$$I_R = I_1 + I_{R1} = 9.6 - j2.6 + 12 - j9 = 21.6 - j11.6 = 24.5 \angle -28.2^\circ$$

Similarly, applying KCL to point B, we get

$$I_Y + I_1 = I_{Y1} \text{ or } I_Y = I_{Y1} - I_1 = -13.8 - j5.9 - 9.6 + j2.6 = -23.4 - j3.3 = 23.6 \angle -172^\circ.$$

**Example 19.57.** A 3- $\phi$ , 434-V, 50-Hz, supply is connected to a 3- $\phi$ , Y-connected induction motor and synchronous motor. Impedance of each phase of induction motor is  $(1.25 + j2.17) \Omega$ . The 3- $\phi$  synchronous motor is over-excited and it draws a current of 120 A at 0.87 leading p.f. Two wattmeters are connected in usual manner to measure power drawn by the two motors. Calculate (i) reading on each wattmeter (ii) combined power factor.

(Elect. Technology, Hyderabad Univ. 1992)

**Solution.** It will be assumed that the synchronous motor is Y-connected. Since it is over-excited it has a leading p.f. The wattmeter connections and phasor diagrams are as shown in Fig. 19.63.

$$Z_1 = 1.25 + j2.17 = 2.5 \angle 60^\circ$$

Fig. 19.63

Phase voltage in each case =  $434/\sqrt{3} = 250 \text{ V}$

$I_1 = 250/2.5 = 100 \text{ A}$  lagging the reference vector  $V_R$  by  $60^\circ$ . Current  $I_2 = 120 \text{ A}$  and leads  $V_R$  by an angle =  $\cos^{-1}(0.87) = 29.5^\circ$

$$\therefore \begin{aligned} I_1 &= 100 \angle 60^\circ = 50 + j86.6; & I_2 &= 120 \angle -29.5^\circ = 104.6 - j59 \\ I_R &= I_1 + I_2 = 154.6 - j27.6 = 156.8 \angle -10.1^\circ \end{aligned}$$

(a) As shown in Fig. 19.63 (b),  $I_R$  lags  $V_R$  by  $10.1^\circ$ . Similarly,  $I_Y$  lags  $V_Y$  by  $10.1^\circ$ .

As seen from Fig. 19.63 (a), current through  $W_1$  is  $I_R$  and voltage across it is  $V_{RB} = V_R - V_B$ . As seen,  $V_{RB} = 434 \text{ V}$  lagging by  $30^\circ$ . Phase difference between  $V_{RB}$  and  $I_R$  is =  $30 - 10.1 = 19.9^\circ$ .

$$\therefore \text{reading of } W_1 = 434 \times 156.8 \times \cos 19.9^\circ = \mathbf{63,970 \text{ W}}$$

Current  $I_Y$  is also (like  $I_R$ ) the vector sum of the line currents drawn by the two motors. It is equal to  $156.8 \text{ A}$  and lags behind its respective phase voltage  $V_Y$  by  $10.1^\circ$ . Current through  $W_2$  is  $I_Y$  and voltage across it is  $V_{YB} = V_Y - V_B$ . As seen,  $V_{YB} = 434 \text{ V}$ . Phase difference between  $V_{YB}$  and  $I_Y$  =  $30^\circ + 10.1^\circ = 40.1^\circ$  (lag).

$$\therefore \text{reading of } W_2 = 434 \times 156.8 \times \cos 40.1^\circ = \mathbf{52,050 \text{ W}}$$

$$(b) \text{ Combined p.f.} = \cos 10.1^\circ = \mathbf{0.9845 \text{ (lag)}}$$

**Example 19.58.** Power in a balanced 3-phase system is measured by the two-wattmeter method and it is found that the ratio of the two readings is 2 to 1. What is the power factor of the system? (Elect. Science-1, Allahabad Univ. 1991)

**Solution.** We are given that  $W_1 : W_2 = 2 : 1$ . Hence,  $W_1 / W_2 = r = 1/2 = 0.5$ . As seen from Art. 19.21.

$$\cos \phi = \frac{1+r}{2\sqrt{1-r+r^2}} = \frac{1+0.5}{2\sqrt{1-0.5+0.5^2}} = \mathbf{0.866 \text{ lag}}$$

**Example 19.59.** A synchronous motor absorbing 50 kW is connected in parallel with a factory load of 200 kW having a lagging power factor of 0.8. If the combination has a power factor of 0.9 lagging, find the kVAR supplied by the motor and its power factor.

(Elect. Machines, A.M.I.E. Sec B)

**Solution.** Load kVA =  $200/0.8 = 250$

Load kVAR =  $250 \times 0.6 = 150$  (lag) [ $\cos \phi = 0.8$   $\sin \phi = 0.6$ ]

Total combined load =  $50 + 200 = 250$  kW

kVA of combined load =  $250/0.9 = 277.8$

Combined kVAR =  $277.8 \times 0.4356 = 121$  (inductive) (combined  $\cos \phi = 0.9$ ,  $\sin \phi = 0.4356$ )

Hence, leading kVAR supplied by synch, motor =  $150 - 121 = 29$  (capacitive)

kVA of motor alone =  $\sqrt{(kW)^2 + (kVAR)^2} = \sqrt{50^2 + 29^2} = 57.8$

p.f. of motor =  $kW/kVA = 50/57.8 = 0.865$  (leading)

**Example 19.60.** A star-connected balanced load is supplied from a 3-phase balanced supply with a line voltage of 416 V at a frequency of 50 Hz. Each phase of load consists of a resistance and a capacitor joined in series and the readings on two wattmeters connected to measure the total power supplied are 782 W and 1980 W, both positive. Calculate (a) the power factor of the circuit (b) the line current and (c) the capacitance of each capacitor.

(Elect. Machinery-I, Bombay Univ.)

**Solution.**  $W_1 = 728$  and  $W_2 = 1980$

For a leading p.f.  $\tan \phi = -\sqrt{3} \frac{W_1 - W_2}{W_1 + W_2} \therefore \tan \phi = -\sqrt{3} \times \frac{(782 - 1980)}{782 + 1980} = 0.75$

From tables,  $\phi = 36^\circ 54'$

(a)  $\therefore \cos \phi = \cos 36^\circ 54' = 0.8$  (leading)

(b) power =  $\sqrt{3} V_L I_L \cos \phi$  or  $W_1 + W_2 = \sqrt{3} V_L I_L \cos \phi$

or  $(782 + 1980) = \sqrt{3} \times 416 \times I_L \times 0.8 \therefore I_L = I_{ph} = 4.8$  A

(c) Now  $V_{ph} = 416 / \sqrt{3}$  V  $\therefore Z_{ph} = 416 / \sqrt{3} \times 4.8 = 50 \Omega$

$\therefore$  In Fig. 19.64,  $Z_{ph} = 50 \angle -36^\circ 54' = 50(0.8 - j0.6) = 40 - j30$

Capacitive reactance  $X_C = 30$ ; or  $\frac{1}{2\pi \times 50 \times C} = 30 \therefore C = 106 \mu\text{F}$ .

Fig. 19.64

**Example 19.61.** The two wattmeters A and B, give readings as 5000 W and 1000 W respectively during the power measurement of 3- $\phi$ , 3-wire, balanced load system. (a) Calculate the power and power factor if (i) both meters read direct and (ii) one of them reads in reverse. (b) If the voltage of the circuit is 400 V, what is the value of capacitance which must be introduced in each phase to cause the whole of the power to appear on A. The frequency of supply is 50 Hz.

(Elect. Engg-I, Nagpur Univ. 1992)

**Solution.** (a) (i) Both Meters Read Direct

$W_1 = 5000$  W;  $W_2 = 1000$  W;  $\therefore W_1 + W_2 = 6000$  W;  $W_1 - W_2 = 4000$  W

$$\tan \phi = \sqrt{3}(W_1 - W_2) / (W_1 + W_2) = \sqrt{3} \times 4000 / 6000 = 1.1547$$

$$\therefore \phi = \tan^{-1}(1.1547) = 49.1^\circ; \text{ p.f.} = \cos 49.1^\circ = 0.655 \text{ (lag)}$$

$$\text{Total power} = 5000 + 1000 = 6000 \text{ W}$$

**(ii) One Meter Reads in Reverse**

$$\text{In this case, } \tan \phi = \sqrt{3}(W_1 + W_2) / (W_1 - W_2) = \sqrt{3} \times 6000 / 4000 = 2.598$$

$$\therefore \phi = \tan^{-1}(2.598) = 68.95^\circ; \text{ p.f.} = \cos 68.95^\circ = 0.36 \text{ (lag)}$$

$$\text{Total power} = W_1 + W_2 = 5000 - 1000 = 4000 \text{ W}$$

...Art.

**(b)** The whole of power would be measured by wattmeter  $W_1$  if the load power factor is 0.5 (lagging) or less. It means that in the present case p.f. of the load will have to be reduced from 0.655 to 0.5. In other words, capacitive reactance will have to be introduced in each phase of the load in order to partially neutralize the inductive-reactance.

$$\text{Now, } \sqrt{3}V_L I_L \cos \phi = 6000 \text{ or } \sqrt{3} \times 400 I_L \times 0.655 = 6000$$

$$\therefore I_L = 13.2 \text{ A}; \therefore I_{ph} = 13.2 / \sqrt{3} = 7.63 \text{ A}$$

$$Z_{ph} = V_{ph} / I_{ph} = 400 / 7.63 = 52.4 \Omega$$

$$X_L = Z_{ph} \sin \phi = 52.4 \times \sin 49.1^\circ = 39.6 \Omega$$

**When p.f. = 0.5**

$$\sqrt{3} \times 400 \times I_L \times 0.5 = 6000; I_L = 17.32 \text{ A}; I_{ph} = 17.32 / \sqrt{3} = 10 \text{ A}; Z_{ph} = 400 / 10 = 40 \Omega$$

$$\cos \phi = 0.5; \phi = 60^\circ; \sin 60^\circ = 0.866; X = Z_{ph} \sin \phi = 40 \times 0.866 = 35.4 \Omega$$

$$\therefore X = X_L - X_C = 35.4 \text{ or } 39.6 - X_C = 35.4; \therefore X_C = 4.2 \Omega.$$

$$\text{If } C \text{ is the required capacitance, then } 4.2 = 1 / 2\pi \times 50 \times C; \therefore C = 758 \mu\text{F}.$$

### Tutorial Problems No. 19.2

**1.** Two wattmeters connected to measure the input to a balanced three-phase circuit indicate 2500 W and 500 W respectively. Find the power factor of the circuit (a) when both readings are positive and (b) when the latter reading is obtained after reversing the connections to the current coil of one instrument.

**[(a) 0.655 (b) 0.3591] (City & Guilds, London)**

**2.** A 400-V, 3-phase induction motor load takes 900 kVA at a power factor of 0.707. Calculate the kVA rating of the capacitor bank to raise the resultant power factor of the installation of 0.866 lagging.

Find also the resultant power factor when the capacitors are in circuit and the motor load has fallen to 300 kVA at 0.5 power factor.

**[296 kVA, 0.998 leading] (City & Guilds, London)**

**3.** Two wattmeters measure the total power in three-phase circuits and are correctly connected. One reads 4,800 W while other reads backwards. On reversing the latter, it reads 400 W. What is the total power absorbed by the circuit and the power factor?

**[4400 W; 0.49] (Sheffield Univ. U.K.)**

**4.** The power taken by a 3-phase, 400-V motor is measured by the two wattmeter method and the readings of the two wattmeters are 460 and 780 watts respectively. Estimate the power factor of the motor and the line current.

**[0.913, 1.96 A] (City & Guilds, London)**

**5.** Two wattmeters,  $W_1$  and  $W_2$  connected to read the input to a three-phase induction motor running unloaded, indicate 3 kW and 1 kW respectively. On increasing the load, the reading on  $W_1$  increases while that on  $W_2$  decreases and eventually reverses.

Explain the above phenomenon and find the unloaded power and power factor of the motor.

**[2 kW, 0.287 lag] (London Univ.)**

**6.** The power flowing in a 3- $\phi$ , 3-wire, balanced-load system is measured by the two wattmeter method. The reading on wattmeter A is 5,000 W and on wattmeter B is -1,000 W

(a) What is the power factor of the system?

(b) If the voltage of the circuit is 440, what is the value of capacitance which must be introduced into each phase to cause the whole of the power measured to appear on wattmeter A?

**[0.359; 5.43  $\Omega$ ] (Meters and Meas. Insts. A.M.I.E.E. London)**

**7.** Two wattmeters are connected to measure the input to a 400 V; 3-phase, connected motor outputting 24.4 kW at a power factor of 0.4 (lag) and 80% efficiency. Calculate the

(i) resistance and reactance of motor per phase

(ii) reading of each wattmeters.

**[(i) 2.55 Ω; 5.85 Ω; (ii) 34,915 W; - 4850 W] (Elect. Machines, A.M.I.E. Sec. B, 1993)**

**8.** The readings of the two instruments connected to a balanced three-phase load are 128 W and 56 W. When a resistor of about 25 Ω is added to each phase, the reading of the second instrument is reduced to zero. State, giving reasons, the power in the circuit before the resistors were added. **[72 W] (London Univ.)**

**9.** A balanced star-connected load, each phase having a resistance of 10 Ω and inductive reactance of 30 Ω is connected to 400-V, 50-Hz supply. The phase rotation is red, yellow and blue. Wattmeters connected to read total power have their current coils in the red and blue lines respectively. Calculate the reading on each wattmeter and draw a vector diagram in explanation. **[2190 W, - 583 W] (London Univ.)**

**10.** A 7.46 kW induction motor runs from a 3-phase, 400-V supply. On no-load, the motor takes a line current of 4 A at a power factor of 0.208 lagging. On full load, it operates at a power factor of 0.88 lagging and an efficiency of 89 per cent. Determine the readings on each of the two wattmeters connected to read the total power on (a) no load and (b) full load. **[1070 W, - 494 W; 5500 W; 2890 W]**

**11.** A balanced inductive load, connected in star across 415-V, 50-Hz, three-phase mains, takes a line current of 25A. The phase sequence is RYB. A single-phase wattmeter has its current coil connected in the R line and its voltage coil across the line YB. With these connections, the reading is 8 kW. Draw the vector diagram and find (i) the kW (ii) the kVAR (iii) the kVA and (iv) the power factor of the load.

**[(i) 11.45 kW (ii) 13.87 kVAR (iii) 18 kVA (iv) 0.637] (City & Guilds, London)**

## 19.27. Double Subscript Notation

In symmetrically-arranged networks, it is comparatively easier and actually more advantageous, to use single-subscript notation. But for unbalanced 3-phase circuits, it is essential to use double subscript notation, in order to avoid unnecessary confusion which is likely to result in serious errors.

Suppose, we are given two coils whose induced e.m.f.s. are 60° out of phase with each other [Fig. 19.65 (a)]. Next, suppose that it is required to connect these coils in additive series *i.e.* in such

Fig. 19.65

a way that their e.m.f.s. add at an angle of 60°. From the information given, it is impossible to know whether to connect terminal 'a' to terminal 'c' or to terminal 'd'. But if additionally it were given that e.m.f. from terminal 'c' to terminal 'd' is 60° out of phase with that from terminal 'a' to terminal 'b', then the way to connect the coils is definitely fixed, as shown in Fig. 19.59 (b) and 19.60 (a). The double-subscript notation is obviously very convenient in such cases. The order in which these subscripts are written indicates the direction along which the voltage acts (or current flows). For example the e.m.f. 'a' to 'b' [Fig. 19.59 (a)], may be written as  $E_{ab}$  and that from 'c' to 'd' as  $E_{cd}$ .... The e.m.f. between 'a' and 'd' is  $E_{ad}$  where  $E_{ad} = E_{ab} + E_{cd}$  and is shown in Fig. 19.59 (b).

**Example 19.62.** If in Fig. 19.60 (a), terminal 'b' is connected to 'd', find  $E_{ac}$  if  $E = 100$  V.

**Solution.** Vector diagram is shown in Fig. 19.60 (b)

Obviously,  $E_{ac} = E_{ab} + E_{dc} = E_{ab} + (-E_{cd})$

Hence,  $E_{cd}$  is reversed and added to  $E_{ab}$  to get  $E_{ac}$  as shown in Fig. 19.60 (b). The magnitude of resultant vector is

$$E_{ac} = 2 \times 100 \cos 120^\circ / 2 = 100 \text{ V}; \quad E_{ac} = 100 \angle -60^\circ$$

**Example 19.62(a).** In Fig. 19.66 (a) with terminal 'b' connected to 'd', find  $E_{ca}$ .

**Solution.**  $E_{ca} = E_{cd} + E_{ba} = E_{cd} + (-E_{ab})$

As shown in Fig. 19.67, vector  $E_{ab}$  is reversed and then combined with  $E_{cd}$  to get  $E_{ca}$ .

Magnitude of  $E_{ca}$  is given by  $2 \times 100 \times \cos 60^\circ = 100$  V but it leads  $E_{ab}$  by  $120^\circ$ .

$\therefore E_{ca} = 100 \angle 120^\circ$

Fig. 19.66

Fig. 19.67

In Fig. 19.68 (b) is shown the vector diagram of the e.m.fs induced in the three phases 1, 2, 3 (or R, Y, B) of a 3-phase alternator [Fig.19.68 (a)]. According to double subscript notation, each phase e.m.f. may be written as  $E_{01}$ ,  $E_{02}$  and  $E_{03}$ , the order of the subscripts indicating the direction in which the e.m.fs. act. It is seen that while passing from phase 1 to phase 2 through the external circuit, we are in opposition to  $E_{02}$ .

$$E_{12} = E_{20} + E_{01} = (-E_{02}) + E_{01} = E_{01} - E_{02}$$

Fig. 19.68

Fig. 19.69

It means that for obtaining  $E_{12}$ ,  $E_{20}$  has to be reversed to obtain  $-E_{02}$  which is then combined with  $E_{01}$  to get  $E_{12}$  (Fig. 19.69). Similarly,

$$E_{23} = E_{30} + E_{02} = (-E_{03}) + E_{02} = E_{02} - E_{03}$$

$$E_{31} = E_{10} + E_{03} = (-E_{01}) + E_{03} = E_{03} - E_{01}$$

By now it should be clear that double-subscript notation is based on lettering every junction and terminal point of diagrams of connections and on the use of two subscripts with all vectors representing voltage or current. The subscripts on the vector diagram, taken from the diagram of connections, indicate that the positive direction of the current or voltage is from the first subscript to the second. For example, according to this notation  $I_{ab}$  represents a current whose +ve direction is from a to b in the branch ab of the circuit in the diagram of connections. In the like manner,  $E_{ab}$  represents the e.m.f. which produces this current. Further,  $I_{ba}$  will represent a current flowing from b to a, hence its vector will be drawn equal to but in a direction opposite to that of  $I_{ab}$ , i.e.  $I_{ab}$  and  $I_{ba}$  differ in phase by  $180^\circ$  although they do not differ in magnitude.

Fig. 19.69 (a)

In single subscript notation (i.e. the one in which single subscript is used) the +ve directions are fixed by putting arrows on the circuit diagrams as shown in Fig. 19.69 (a). According to this notation

$$E_{12} = -E_2 + E_1 = E_1 - E_2; E_{23} = -E_3 + E_2 = E_2 - E_3 \text{ and } E_{31} = -E_1 + E_3 = E_3 - E_1$$

$$\text{or } \mathbf{E}_{RY} = \mathbf{E}_R - \mathbf{E}_Y; \mathbf{E}_{YB} = \mathbf{E}_Y - \mathbf{E}_B; \mathbf{E}_{BR} = \mathbf{E}_B - \mathbf{E}_R$$

**Example 19.63.** Given the phasors  $V_{12} = 10\angle 30^\circ$ ;  $V_{23} = 5\angle 0^\circ$ ;  $V_{14} = 6\angle -60^\circ$ ;  $V_{45} = 10\angle 90^\circ$ . Find (i)  $V_{13}$  (ii)  $V_{34}$  and (iii)  $V_{25}$ .

**Solution.** Different points and the voltage between them have been shown in Fig. 19.70.

(i) Using KVL, we have

$$V_{12} + V_{23} + V_{31} = 0 \text{ or } V_{12} + V_{23} - V_{13} = 0$$

$$\text{or } V_{13} = V_{12} + V_{23} = 10\angle 30^\circ + 5\angle 0^\circ = 8.86 + j5 + 5 \\ = 13.86 + j5 = 14.7\angle 70.2^\circ$$

(ii) Similarly,  $V_{13} + V_{34} + V_{41} = 0$  or  $V_{13} + V_{34} - V_{14} = 0$

$$\text{or } V_{34} = V_{14} - V_{13} = 6\angle -60^\circ - 14.7\angle 70.2^\circ \\ = 3 - j5.3 - 13.86 - j5 = -10.86 - j10.3 = 15\angle 226.5^\circ$$

(iii) Similarly,  $V_{23} + V_{34} + V_{45} + V_{52} = 0$

$$\text{or } V_{23} + V_{34} + V_{45} - V_{52} = 0$$

$$\text{or } V_{52} = V_{23} + V_{34} + V_{45} = 5\angle 0^\circ + 15\angle 226.5^\circ + 10\angle 90^\circ \\ = 5 - 10.86 - j10.3 + j10 = -5.86 - j0.3 = 5.86\angle -2.9^\circ$$

Fig. 19.70

**Example 19.64.** In a balanced 3-phase Y-connected voltage source having phase sequence abc,  $V_{an} = 230\angle 30^\circ$ . Calculate analytically (i)  $V_{bn}$  (ii)  $V_{cn}$  (iii)  $V_{ab}$  (iv)  $V_{bc}$  and (v)  $V_{ca}$ . Show the phase and line voltages on a phasor diagram.

**Solution.** It should be noted that  $V_{an}$  stands for the voltage of terminal a with respect to the neutral point n. The usual positive direction of the phase voltages are as shown in Fig. 19.71 (a). Since the 3-phase system is balanced, the phase differences between the different phase voltages are  $120^\circ$ .

$$(i) V_{bn} = \angle -120^\circ = 230 \angle (30^\circ - 120^\circ) = 230\angle -90^\circ$$

$$(ii) V_{cn} = V_{an}\angle 120^\circ = 230 \angle (30^\circ + 120^\circ) = 230\angle 150^\circ$$

... Fig. 19.71 (b)

Fig. 19.71

(iii) It should be kept in mind that  $V_{ab}$  stands for the voltage of point a with respect to point b. For this purpose, we start from the reference point b in Fig. 19.71 (a) and go to point a and find the sum of the voltages met on the way. As per sign convention given in Art. 19.27 as we go from b to n, there is a fall in voltage of by an amount equal to  $V_{bn}$ . Next as we go from n to a, there is increase of voltage given by  $V_{an}$ .

$$\therefore V_{ab} = -V_{bn} + V_{an} = V_{an} - V_{bn} = 230\angle 30^\circ - 230\angle -90^\circ \\ = 230(\cos 30^\circ + j\sin 30^\circ) - 230(0 - j\sin 90^\circ)$$

$$= 230 \frac{\sqrt{3}}{2} j \frac{1}{2} j 230 \quad 230 \frac{\sqrt{3}}{2} j \frac{3}{2} = 230\sqrt{3} \frac{1}{2} j \frac{\sqrt{3}}{2} \quad 400 \quad 60$$

(iv)  $V_{bc} = V_{bn} - V_{cn} = 230 \angle -90^\circ - 230 \angle 150^\circ = -j230 - 230$

$$\frac{\sqrt{3}}{2} j \frac{1}{2} \quad 230\sqrt{3} \frac{1}{2} j \frac{\sqrt{3}}{2} \quad 400 \quad 60$$

(v)  $V_{ca} \quad V_{cn} \quad V_{an} \quad 230 \quad 150 \quad 230 \quad 30 \quad \frac{\sqrt{3}}{2} j \frac{1}{2} \quad 230 \frac{\sqrt{3}}{2} j \frac{1}{2} \quad 400 \quad 400 \quad 180$

These line voltages along with the phase voltages have been shown in the phasor diagram of Fig. 19.71 (b).

**Example 19.65.** Three non-inductive resistances, each of  $100 \Omega$  are connected in star to a 3-phase, 440-V supply. Three equal choking coils are also connected in delta to the same supply; the resistance of one coil being equal to  $100 \Omega$ . Calculate (a) the line current and (b) the power factor of the system. **(Elect. Technology-II, Sambal Univ.)**

**Solution.** The diagram of connections and the vector diagram of the Y- and  $\Delta$ -connected impedances are shown in Fig. 19.72.

The voltage  $E_{10}$  between line 1 and neutral is taken along the X-axis. Since the load is balanced, it will suffice to determine the current in one line only. Applying Kirchoff's Law to junction 1, we have

Fig. 19.72

$$I'_{11} = I_{10} + I_{12} + I_{13}$$

Let us first get the vector expressions for  $E_{10}$ ,  $E_{20}$  and  $E_{30}$

$$E_{10} = \frac{440}{\sqrt{3}} (1 + j0) = 254 + j0, \quad E_{20} = 254 \frac{1}{2} j \frac{\sqrt{3}}{2} = -127 - j220$$

$$E_{30} = 254 \frac{1}{2} j \frac{\sqrt{3}}{2} = -127 + j220$$

Let us now derive vector expressions for  $V_{12}$  and  $V_{31}$ :

$$V_{10} = E_{10} + E_{02} = E_{10} - E_{20} = (254 + j0) - (-127 - j220) = 381 + j220$$

$$V_{13} = E_{10} + E_{03} = E_{10} - E_{30} = (254 - j0) - (-127 + j220) = 381 - j220$$

$$I_{10} = \frac{E_{10}}{Z_Y} = \frac{254}{100} j0 = 2.54 \quad j0, \quad I_{12} = \frac{V_{13}}{Z} = \frac{381 - j220}{j100} = 2.2 \quad j3.81 \quad 4.4 \quad 60$$

$$I_{13} = \frac{V_{13}}{Z_{\Delta}} = \frac{381 - j220}{j100} = -2.2 - j3.81 = 4.4 \angle -120^\circ$$

(a)  $I'_{11} = (2.54 + j0) + (2.2 - j3.81) + (-2.2 - j3.81) = (2.54 - j7.62) = 8.03 \angle -71.6^\circ$

Fig. 19.73

$$(b) \text{ p.f.} = \cos 71.6^\circ = 0.316 \text{ (lag)}$$

#### Alternative Method

This question may be easily solved by  $\Delta/Y$  conversion. The star equivalent of the delta reactance is  $100/3 \Omega$  per phase.

As shown in Fig. 19.73, there are now two parallel circuits across each phase, one consisting of a resistance of  $100 \Omega$  and the other of a reactance of  $100/3 \Omega$

Taking  $E_{10}$  as the reference vector, we have

$$E_{10} = (254 + j0)$$

$$I_1 = \frac{254 - j0}{100} = 2.54 - j0; \quad I_2 = \frac{254 - j0}{j100/3} = j7.62$$

$$\text{Line current } I = (2.54 - j0) + (-j7.62) = (2.54 - j7.62) = 8.03 \angle -71.6^\circ \dots \text{ Fig. 19.73 (b)}$$

### 19.28. Unbalanced Loads

Any polyphase load in which the impedances in one or more phases differ from the impedances of other phases is said to be an unbalanced load. We will now consider different methods to handle unbalanced star-connected and delta-connected loads.

### 19.29. Unbalanced $\Delta$ -connected Load

Unlike unbalanced  $Y$ -connected load, the unbalanced  $\Delta$ -connected load supplied from a balanced 3-phase supply does not present any new problems because the voltage across each load phase is fixed. It is independent of the nature of the load and is equal to line voltage. In fact, the problem resolves itself into three independent single-phase circuits supplied with voltages which are  $120^\circ$  apart in phase.

The different phase currents can be calculated in the usual manner and the three line currents are obtained by taking the vector difference of phase currents in pairs.

If the load consists of three different pure resistances, then trigonometrical method can be used with advantage, otherwise symbolic method may be used.

**Example 19.66.** A 3-phase, 3-wire, 240 volt, CBA system supplies a delta-connected load in which  $Z_{AB} = 25 \angle 90^\circ$ ,  $Z_{BC} = 15 \angle 30^\circ$ ,  $Z_{CA} = 20 \angle 0^\circ$  ohms. Find the line currents and total power.

(Advanced Elect. Machines A.M.I.E. Sec. B, Summer 1991)

**Solution.** As explained in Art. 19.2, a 3-phase system has only two possible sequences :  $ABC$  and  $CBA$ . In the  $ABC$  sequence, the voltage of phase  $B$  lags behind voltage of phase  $A$  by  $120^\circ$  and that of phase  $C$  lags behind phase  $A$  voltage by  $240^\circ$ . In the  $CBA$  phase which can be written as  $A \rightarrow C \rightarrow B$ , voltage of  $C$  lags behind voltage  $A$  by  $120^\circ$  and that of  $B$  lags behind voltage  $A$  by  $240^\circ$ . Hence, the phase voltage which can be written as

$$E_{AB} = E \angle 0^\circ; \quad E_{BC} = E \angle -120^\circ$$

$$\text{and } E_{CA} = E \angle -240^\circ \text{ or } E_{CA} = E \angle 120^\circ$$

Fig. 19.74

$$\therefore I_{AB} = \frac{E_{AB}}{Z_{AB}} = \frac{240\angle 0^\circ}{25\angle 90^\circ} = 9.6\angle -90^\circ = -j9.6 \text{ A}$$

$$I_{BC} = \frac{E_{BC}}{Z_{BC}} = \frac{240\angle 120^\circ}{15\angle 30^\circ} = 16\angle 90^\circ = j16 \text{ A}$$

$$I_{CA} = \frac{E_{CA}}{Z_{CA}} = \frac{240\angle -120^\circ}{20\angle 0^\circ} = 12\angle -120^\circ = 12(0.5 - j0.866) = (-6 - j10.4) \text{ A}$$

The circuit is shown in Fig. 19.74.

$$\text{Line current } I_{AA} = I_{AB} + I_{AC} = I_{AB} - I_{CA} = -j9.6 - (-6 - j10.4) = 6 + j0.08$$

$$\text{Line current } I_{BB} = I_{BC} - I_{AB} = j16 - (-j9.6) = j25.6 \text{ A}$$

$$I_{CC} = I_{CA} - I_{BC} = (-6 - j10.4) - j16 = (-6 - j26.4) \text{ A}$$

$$\text{Now, } R_{AB} = 0; R_{BC} = 15 \cos 30 = 13 \Omega; R_{CA} = 20 \Omega$$

Power

$$W_{AB} = 0; W_{BC} = I_{BC}^2 R_{BC} = 16^2 \times 13 = 3328 \text{ W}; W_{CA} = I_{CA}^2 \times R_{CA} = 27^2 \times 20 = 14,580 \text{ W}$$

$$\text{Total Power} = 3328 + 14580 = 17,908 \text{ W}$$

**Example 19.67.** In the network of Fig. 19.75,  $E_{na} = 230\angle 0^\circ$  and the phase sequence is abc. Find the line currents  $I_a$ ,  $I_b$  and  $I_c$  as also the phase currents  $I_{AB}$ ,  $I_{BC}$  and  $I_{CA}$ .  $E_{na}$ ,  $E_{nb}$ ,  $E_{nc}$  is a balanced three-phase voltage system with phase sequence abc.

(Network Theory, Nagpur Univ. 1993)

**Solution.** Since the phase sequence is abc, the generator phase voltages are:

$$E_{na} = 320\angle 0^\circ; E_{nb} = 230\angle -120^\circ; E_{nc} = 230\angle 120^\circ$$

Fig. 19.75

As seen from the phasor diagram of Fig. 19.75 (b), the line voltages are as under :-

$$V_{ab} = E_{na} - E_{nb}; V_{bc} = E_{nb} - E_{nc}; V_{ca} = E_{nc} - E_{na}$$

$\therefore V_{ab} = \sqrt{3} \times 230\sqrt{30^\circ} = 400\angle 30^\circ$  i.e. it is ahead of the reference generator phase voltage  $E_{na}$  by  $30^\circ$ .

$$V_{bc} = \sqrt{3} \times 230\angle 90^\circ = 400\angle -90^\circ. \text{ This voltage is } 90^\circ \text{ behind } E_{na} \text{ but } 120^\circ \text{ behind } V_{ab}.$$

$V_{ca} = \sqrt{3} \times 230\angle 150^\circ = 400\angle 150^\circ$  or  $\angle -210^\circ$ . This voltage leads reference voltage  $E_{na}$  by  $150^\circ$  but leads  $V_{ab}$  by  $120^\circ$ .

These voltages are applied across the unbalanced  $\Delta$ -connected load as shown in Fig. 19.75 (a).

$$Z_{AB} = 30 + j40 = 50\angle 53.1^\circ; Z_{BC} = 50 - j30 = 58.3\angle -31^\circ,$$

$$Z_{CA} = 40 + j30 = 50\angle 36.9^\circ$$

$$I_{AB} = \frac{V_{ab}}{Z_{AB}} = \frac{400\angle 30^\circ}{50\angle 53.1^\circ} = 8\angle -23.1^\circ = 7.36 - j3.14$$

$$I_{BC} = \frac{V_{bc}}{Z_{BC}} = \frac{400\angle -90^\circ}{58.3\angle -31^\circ} = 6.86\angle -59^\circ = 3.53 - j5.88$$

$$I_{CA} = \frac{V_{ca}}{Z_{CA}} = \frac{400 \angle 150^\circ}{50 \angle 36.9^\circ} = 8 \angle 113.1^\circ = 3.14 + j7.36$$

$$I_a = I_{AB} - I_{CA} = 7.36 - j3.14 + 3.14 - j7.36 = 10.5 - j10.5 = 14.85 \angle -45^\circ$$

$$I_b = I_{BC} - I_{AB} = 3.53 - j5.88 - 7.36 + j3.14 = -3.83 - j2.74 = 4.71 \angle -215.6^\circ$$

$$I_c = I_{CA} - I_{BC} = -3.14 + j7.36 - 3.53 + j5.88 = -6.67 + j13.24 = 14.8 \angle 116.7^\circ$$

**Example 19.68.** For the unbalanced  $\Delta$ -connected load of Fig. 19.76 (a), find the phase currents, line currents and the total power consumed by the load when phase sequence is (a) abc and (b) acb.

**Solution.** (a) Phase sequence abc (Fig. 19.76).

Let  $V_{ab} = 100 \angle 0^\circ = 100 + j0$

$$V_{bc} = 100 \quad 120 \quad 100 \quad \frac{1}{2} j \frac{\sqrt{3}}{2} \quad 50 \quad j86.6$$

$$V_{ca} = 100 \quad 102 \quad 100 \quad \frac{1}{2} j \frac{\sqrt{3}}{2} \quad 50 \quad j86.6$$

Fig. 19.76

(i) Phase currents

$$\text{Phase current, } I_{ab} = \frac{V_{ab}}{Z_{ab}} = \frac{100 \quad j0}{6 \quad j8} = 6 \quad j8 \quad 10 \quad 53.8$$

$$\text{Similarly, } I_{bc} = \frac{V_{bc}}{Z_{bc}} = \frac{30 \quad j86.6}{8 \quad j6} = 9.2 \quad j3.93 \quad 10 \quad 156.52$$

$$I_{ca} = \frac{V_{ca}}{Z_{ca}} = \frac{50 \quad j86.6}{4 \quad j3} = 18.39 \quad j7.86 \quad 20 \quad 156.52$$

(ii) Line Currents

$$\begin{aligned} \text{Line Current } I_a &= I_{ab} - I_{ca} = (6 \quad j8) - (18.39 \quad j7.86) \\ &= 24.39 - j15.86 = 29.1 \angle -33^\circ 2' \end{aligned}$$

$$\begin{aligned} \text{Similarly, } I_b &= I_{bc} - I_{ab} = (9.2 \quad j3.93) - (6 \quad j8) = 15.2 \quad j4.07 \\ &= 15.73 \angle 165.30^\circ \end{aligned}$$

$$\begin{aligned} I_c &= I_{ca} - I_{bc} = (18.39 \quad j7.86) - (9.2 \quad j3.93) \\ &= 9.19 + j11.79 = 14.94 \angle 52^\circ 3' \end{aligned}$$

Check  $\Sigma I = 0 + j0$

**(iii) Power**

$$W_{ab} = I_{ab}^2 R_{ab} = 10^2 \times 6 = 600 \text{ W}$$

$$W_{bc} = I_{bc}^2 R_{bc} = 10^2 \times 8 = 800 \text{ W}$$

$$W_{ca} = I_{ca}^2 R_{ca} = 20^2 \times 4 = 1600 \text{ W}$$

$$\text{Total} = 3000 \text{ W}$$

**(b) Phase sequence acb** (Fig. 19.77)

Here,

$$\mathbf{V}_{ab} \quad 100 \quad 0 \quad 100 \quad j9$$

$$\mathbf{V}_{bc} \quad 100 \quad 120 \quad 50 \quad 86.6$$

$$\mathbf{V}_{ca} \quad 100 \quad 120 \quad 50 \quad j86.6$$

**(i) Phase Currents**

$$\mathbf{I}_{ab} \quad \frac{100}{6 - j8} \quad 6 \quad j8 \quad 10 \quad 53 \quad 8$$

$$\mathbf{I}_{bc} \quad \frac{50}{8 - j6} \quad \frac{j86.6}{j6} = (1.2 + j9.93) = 10 \angle 83^\circ 8'$$

$$\mathbf{I}_{ca} \quad \frac{50}{7 - j3} \quad \frac{j86.6}{j3} = (2.4 - j19.86) = 20 \angle -83^\circ 8'$$

**(ii) Line Currents**

$$\mathbf{I}_{a'a} = \mathbf{I}_{ab} + \mathbf{I}_{ac} = \mathbf{I}_{ab} - \mathbf{I}_{ca}$$

$$= (6 - j8) - (2.4 - j19.86) = (3.6 + j11.86) = 12.39 \angle 73^\circ 6'$$

$$\mathbf{I}_{bb} \quad (1.2 \quad j9.93) \quad (6 \quad j8) \quad (4.8 \quad j17.93) \quad 18.56 \quad 105$$

$$\mathbf{I}_{cc} \quad (2.4 \quad j19.86) \quad (1.2 \quad j9.93) \quad (1.2 \quad j29.79) \quad 29.9 \quad 87 \quad 42$$

It is seen that  $\Sigma \mathbf{I} = 0 + j0$

**(iii) Power**

$$W_{ab} = 10^2 \times 6 = 600 \text{ W}$$

$$W_{bc} = 10^2 \times 8 = 800 \text{ W}$$

$$W_{ca} = 20^2 \times 4 = 1600 \text{ W}$$

$$\text{Total} = 3000 \text{ W}$$

- as before

It will be seen that the effect of phase reversal on an unbalanced  $\Delta$ -connected load is as under:

**(i)** phase currents change in angle only, their magnitudes remaining the same

**(ii)** consequently, phase powers remain unchanged

**(iii)** line currents change both in magnitude and angle.

The adjoining tabulation emphasizes the effect of phase sequence on the line currents drawn by an unbalanced 3-phase load.

Line	Ampere Sequence a b c	Sequence c b a
a	29.1 $\angle -33^\circ 2'$	12.39 $\angle 73.1^\circ$
b	15.73 $\angle 165^\circ$	18.56 $\angle 105^\circ$
c	14.94 $\angle 52^\circ 3'$	29.9 $\angle -87.7^\circ$

Fig. 19.77

**Example 19.69.** A balanced 3-phase supplies an unbalanced 3-phase delta-connected load made up of resistors  $100 \Omega$  and a reactor having an inductance of  $0.3 \text{ H}$  with negligible resistance.  $V_L = 100 \text{ V}$  at  $50 \text{ Hz}$ . Calculate (a) the total power in the system.

(Elect. Engineering-I, Madras Univ.)

Fig. 19.78

**Solution.** The  $\Delta$ -connected load and its phasor diagram are shown in Fig. 19.78 (a).

$$X_L = \omega L = 314.2 \times 0.2 \\ = 94.3 \Omega$$

$$\text{Let } \mathbf{V}_{ab} \begin{bmatrix} 100 & 0 & 100 \\ 100 & 120 & -50 - j86.6 \end{bmatrix} \text{ j}0$$

$$\mathbf{V}_{ca} \begin{bmatrix} 100 & 120 & 50 \\ 100 & 0 & 130 \end{bmatrix} \text{ j}86.6$$

$$\mathbf{I}_{ab} \begin{bmatrix} \frac{V_{ab}}{Z_{ab}} & \frac{100}{100} & 0 \\ 130 & 0 & 1 \end{bmatrix} \text{ j}0$$

$$\mathbf{I}_{bc} \begin{bmatrix} \frac{100}{100} & 0 \\ 100 & 0 \end{bmatrix} \begin{bmatrix} 1.06 & 210 & 0.92 \\ 0 & 0 & j0.53 \end{bmatrix}$$

$$\mathbf{I}_{ca} \begin{bmatrix} \frac{100}{200} & \frac{120}{0} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 0.5 & 120 & 0.25 \\ 0 & 0 & j0.43 \end{bmatrix}$$

Watts in branch  $ab = V_{ab}^2 / R_{ab} = 100^2 / 100 = 100 \text{ W}$ ; VARs = 0

Watts in branch  $bc = 0$ ; VARs =  $100 \times 1.06 = 106 \text{ (lag)}$

Watts in branch  $ca = V_{ca}^2 / R_{ca} = 100^2 / 200 = 50 \text{ W}$ ; VARs = 0

(a) Total power =  $100 + 50 = 150 \text{ W}$ ; VARs = **106 (lag)**

### 19.30. Four-wire Star-connected Unbalanced Load

It is the simplest case of an unbalanced load and may be treated as three separate single-phase systems with a common return wire. It will be assumed that impedance of the line wires and source phase windings is zero. Should such an assumption be unacceptable, these impedances can be added to the load impedances. Under these conditions, source and load line terminals are at the same potential.

Consider the following two cases:

#### (i) Neutral wire of zero impedance

Because of the presence of neutral wire (assumed to behaving zero impedance), the star points of the generator and load are tied together and are at the same potential. Hence, the voltages across the three load impedances are **equalized** and each is equal to the voltage of the corresponding phase of the generator. In other words, due to the provision of the neutral, each phase voltage is a **forced** voltage so that the three phase voltages are balanced when line voltages are balanced even though phase impedances are unbalanced. However, it is worth noting that a break or open ( $Z_N = \infty$ ) in the neutral wire of a 3-phase, 2-wire system with **unbalanced** load always causes large (in most cases inadmissible) changes in currents and phase voltages. It is because of this reason that no fuses and circuit breakers are ever used in the neutral wire of such a 3-phase system.

The solution for currents follows a pattern similar to that for the unbalanced delta.

Obviously, the vector sum of the currents in the three lines is not zero but is equal to neutral current.

**(ii) Neutral wire with impedance  $Z_N$**

Such a case can be easily solved with the help of Node-pair Voltage method as detailed below. Consider the general case of a  $Y$ -to- $Y$  system with a neutral wire of impedance  $Z_N$  as shown in Fig. 19.79 (a). As before, the impedance of line wires and source phase windings would be assumed to be zero so that the line and load terminals,  $R, Y, B$  and  $R', Y', B'$  are the same respective potentials.

Fig. 19.79

According to Node-pair Voltage method, the above star-to-star system can be looked upon as multi-mesh network with a single pair of nodes *i.e.* neutral points  $N$  and  $N'$ . The node potential *i.e.* the potential difference between the supply and local neutrals is given by

$$V'_{NN} = \frac{E_R Y_R + E_Y Y_Y + E_B Y_B}{Y_R + Y_Y + Y_B + Y_N}$$

where  $Y_R, Y_Y$  and  $Y_B$  represent the **load phase** admittances. Obviously, the load neutral  $N'$  does not coincide with source neutral  $N$ . Hence, load phase voltages are no longer equal to one another even when phase voltages are as seen from Fig. 19.79 (b).

The load phase voltage are given by

$$V'_R = E_R - V'_{NN}; V'_Y = E_Y - V'_{NN} \text{ and } V'_B = E_B - V'_{NN}$$

The phase currents are

$$I_R = V'_R Y_R, I'_Y = V'_Y Y_Y \text{ and } I_B = V'_B Y_B$$

The current in the neutral wire is  $I_N = V'_N Y_N$

**Note.** In the above calculations,  $I_R, I'_R, I_{RR}$

Similarly,  $I_Y = I'_Y = I'_{YY}$  and  $I'_B = I_{BB}$ .

**Example 19.70.** A 3-phase, 4-wire system having a 254-V line-to-neutral has the following loads connected between the respective lines and neutral;  $Z_R = 10 \angle 0^\circ \text{ ohm}$ ;  $Z_Y = 10 \angle 37^\circ \text{ ohm}$  and  $Z_B = 10 \angle -53^\circ \text{ ohm}$ . Calculate the current in the neutral wire and the power taken by each load when phase sequence is (i) RYB and (ii) RBY.

**Solution.** (i) Phase sequence RYB (Fig. 19.80)

$$V_{RN} = 254 \angle 0^\circ; V_{YN} = 254 \angle 120^\circ; V_{BN} = 254 \angle 240^\circ$$

$$I_R = I_{RN} = \frac{V_{RN}}{Z_R} = \frac{254 \angle 0^\circ}{10 \angle 0^\circ} = 25.4 \angle 0^\circ *$$

$$I'_Y = I_{YN} = \frac{254 \angle -120^\circ}{10 \angle 37^\circ} = 25.4 \angle -157^\circ = 25.4(-0.9205 - j0.3907) = -23.38 - j9.95$$

\* This method is similar to Millman's Theorem of Art. 19.32.

Fig. 19.80

$$I_B = I_{BN} = \frac{254 \angle 120^\circ}{10 \angle -53^\circ} = 25.4 \angle 173^\circ = 25.4(-0.9925 + j0.1219) = -25.2 + j3.1$$

$$I_N = -(I_R + I_Y + I_B) = -[25.4 + (-23.38 - j9.55) + (-25.21 + j3.1)] = 23.49 + j6.85$$

$$= \mathbf{24.46 \angle 16^\circ 15'}$$

Now  $R_R = 10 \Omega$ ;  $R_Y = 10 \cos 37^\circ = 8 \Omega$ ;  $R_B = 10 \cos 53^\circ = 6 \Omega$

$$W_R = 25.4^2 \cdot 10 = \mathbf{6,452 \text{ W}}; \quad W_Y = 25.4^2 \cdot 8 = \mathbf{5,162 \text{ W}}$$

$$W_B = 25.4^2 \cdot 6 = \mathbf{3,871 \text{ W}}$$

(ii) Phase sequence **RBV** [Fig. 19.81]

Fig. 19.81

$$V_{RN} = 254 \angle 0^\circ; \quad V_{YN} = 254 \angle 120^\circ$$

$$V_{BN} = 254 \angle 120^\circ$$

$$I_R = \frac{254 \angle 0^\circ}{10 \angle 0^\circ} = 25.4 \angle 0^\circ$$

$$I_Y = \frac{254 \angle 120^\circ}{10 \angle 37^\circ} = 25.4 \angle 83^\circ$$

$$= (3.1 + j25.2) I_B$$

$$I_B = \frac{254 \angle 120^\circ}{10 \angle 53^\circ} = 25.4 \angle 67^\circ = (9.95 + j23.4)$$

$$I_N = -(I_R + I_Y + I_B) = (38.45 - j1.8)$$

$$= -38.45 - j1.8 = 38.5 \angle -177.3^\circ$$

Obviously, power would remain the same because magnitude of branch currents is unaltered. From the above, we conclude that phase reversal in the case of a 4-wire unbalanced load supplied from a balanced voltage system leads to the following changes:

- (i) it changes the angles of phase currents but not their magnitudes.
- (ii) however, power remains unchanged.
- (iii) it changes the magnitude as well as angle of the neutral current  $I_N$

**Example 19.71.** A 3- $\phi$ , 4-wire, 380-V supply is connected to an unbalanced load having phase impedances of:  $Z_R = (8 + j6) \Omega$ ,  $Z_Y = (8 - j6) \Omega$  and  $Z_B = 5 \Omega$ . Impedance of the neutral wire is  $Z_N = (0.5 + j1) \Omega$ .

Ignoring the impedances of line wires and internal impedances of the e.m.f. sources, find the phase currents and voltages of the load.

**Solution.** This question will be solved by using Node-pair Voltage method discussed in Art. 19.30. The admittances of the various branches connected between nodes  $N$  and  $N$  in Fig. 19.82 (a).

$$\begin{aligned}
 Y_R &= 1/Z_R = 1/(8 + j6) = (0.08 - j0.06) \\
 Y_Y &= 1/Z_Y = 1/(8 - j6) = (0.08 + j0.06) \\
 Y_B &= 1/2Z_B = 1/(5 + j0) = 0.2 \\
 Y_N &= 1/Z_N = 1/(0.5 + j1) = (0.4 - j0.8)
 \end{aligned}$$

$$\begin{aligned}
 \text{Let } E_R &= (380/\sqrt{3})\angle 0^\circ = 220\angle 0^\circ = 220 + j0 \\
 E_Y &= 220\angle -120^\circ = 220(-0.5 - j0.866) = -110 - j190 \\
 E_B &= 220\angle 120^\circ = 220(-0.5 + j0.866) = -110 + j190
 \end{aligned}$$

The node voltage between  $N$  and  $N'$  is given by

$$\begin{aligned}
 V'_{NN} &= \frac{E_R Y_R + E_Y Y_Y + E_B Y_B}{Y_R + Y_Y + Y_B + Y_N} \\
 &= \frac{200(0.08 - j0.06) + (-110 - j190)(0.08 + j0.06) + (-110 + j190) \times 0.2}{(0.08 - j0.06) + (0.08 + j0.06) + 0.2 + (0.4 - j0.8)} \\
 &= \frac{-1.8 + j3}{0.76 - j0.8} = -3.41 + j0.76
 \end{aligned}$$

The three load phase voltages are as under:

$V_R$	$E_R$	$V'_{NN}$	220	3.41	$j0.76$	223.41	$j0.76$
$V_Y$	$E_Y$	$V'_{NN}$	( 110	$j90$ )	3.41	$j0.76$	106.59 $j190.76$
$V_B$	$E_B$	$V'_{NN}$	( 110	$j90$ )	3.41	$j0.76$	106.59 $j190.76$

Fig 19.82

$I_R$	$V_R Y_R$	(223.41 $j0.76$ )	(0.08 $j0.06$ )	17.83	$j13.1$	22.1	36.3 A
$I_Y$	$V_Y Y_Y$	( 106.59 $j190.76$ )	(0.08 $j0.06$ )	2.92	$j21.66$	21.86	82.4 A
$I_B$	$V_B Y_B$	( 106.59 $j190.76$ )	0.2	21.33	$j37.85$	43.45	119.4 A
$I_N$	$V_N Y_N$	( 3.41 $j0.76$ )	(0.4 $j0.8$ )	0.76	$j3.03$	3.12	104.1 A

These voltage and currents are shown in the phasor diagram of Fig. 19.82 (b) where displacement of the neutral point has not been shown due to the low value of  $V'_{NN}$ .

**Note.** It can be shown that  $I_N = I'_R + I'_Y + I'_B$

### 19.31. Unbalanced Y-connected Load Without Neutral

When a star-connected load is unbalanced and it has no neutral wire. Then its star point is isolated from the star-point of the generator. The potential of the load star-point is different from that of the generator star-point. The potential of the former is subject to variations according to the imbalance of the load and under certain conditions of loading, the potentials of the two star-point may differ considerably. Such an isolated load star-point or neutral point is called 'floating' neutral point because its potential is always changing and is not fixed.

All  $Y$ -connected unbalanced loads supplied from polyphase systems have floating neutral points without a neutral wire. Any unbalancing of the load causes variations not only of the potential of the star-point but also of the voltages across the different branches of the load. **Hence, in that case, phase voltage of the load is not  $1/\sqrt{3}$  of the line voltage.**

There are many methods to tackle such unbalanced  $Y$ -connected loads having isolated neutral points.

1. By converting the  $Y$ -connected load to an equivalent unbalanced  $\Delta$ -connected load by using  $Y$ - $\Delta$  conversion theorem. The equivalent  $\Delta$ -connection can be solved in Fig. 19.80. The line currents so calculated are equal in magnitude and phase to those taken by the original unbalanced  $Y$ -connected load.

2. By applying Kirchhoff's Laws.

3. By applying Millman's Theorem.

4. By using Maxwell's Mesh or Loop Current Method.

### 19.32. Millman's Theorem

Fig. 19.83 shows a number of linear bilateral admittances,  $Y_1, Y_2, \dots$  connected to a common point or node  $O'$ . The voltages of the free ends of these admittances with respect to another common point  $O$  are  $V_{10}, V_{20}, \dots, V_{n0}$ . Then, according to this theorem, the voltage of  $O'$  with respect to  $O$  is given by

$$V'_{00} = \frac{V_{10}Y_1 + V_{20}Y_2 + V_{30}Y_3 + \dots + V_{n0}Y_n}{Y_1 + Y_2 + Y_3 + \dots + Y_n}$$

Fig. 19.83

$$(V'_{10} - V'_{00})Y_1 + (V'_{20} - V'_{00})Y_2 + \dots + (V'_{k0} - V'_{00})Y_k + \dots = 0$$

$$\text{or } V'_{10}Y_1 + V'_{20}Y_2 + \dots + V'_{k0}Y_k + \dots = V'_{00}(Y_1 + Y_2 + \dots + Y_k + \dots)$$

$$V'_{00} = \frac{V_{10}Y_1 + V_{20}Y_2 + \dots}{Y_1 + Y_2 + \dots}$$

$$\text{or } V'_{00} = \frac{\sum_{k=1}^n V_{k0}Y_k}{\sum_{k=1}^n Y_k}$$

**Proof.** Consider the closed loop  $O'Ok$ . The sum of p.d.s. around it is zero. Starting from  $O'$  and going anticlockwise, we have

$$V'_{00} + V_{ok} + V'_{ko} = 0$$

$$\therefore V'_{ko} = -V_{ok} - V'_{00} = V_{ko} - V'_{00}$$

$$\text{Current through } Y_k \text{ is } I'_{ko}$$

$$= V'_{ko}Y_k = (V_{ko} - V'_{00})Y_k =$$

By Kirchhoff's Current Law, sum of currents meeting at point  $O'$  is zero.

$$\therefore I'_{10} + I'_{20} + \dots + I'_{k0} + \dots + I'_{n0} = 0$$

### 19.33. Application of Kirchhoff's Laws

Consider the unbalanced  $Y$ -connected load of Fig. 19.84. Since the common point of the three load impedances is not at the potential of the neutral, it is marked  $O'$  instead of  $N^*$ . Let us assume the

\* For the sake of avoiding printing difficulties, we will take the load star point as  $O$  instead of  $O'$  for this article.

phase sequence  $V_{ab}, V_{bc}, V_{ca}$  i.e.  $V_{ab}$  leads  $V_{bc}$  and  $V_{bc}$  leads  $V_{ca}$ . Let the three branch impedances be  $Z_{ca}, Z_{ab}$  and  $Z_{ac}$ , however, since double subscript notation is not necessary for a Y-connected impedances in order to indicate to which phase it belongs, single-subscript notation may be used with advantage. Therefore  $Z_{oa}, Z_{ob}, Z_{oc}$  can be written as  $Z_a, Z_b, Z_c$  respectively. It may be pointed out that double-subscript notation is essential for mesh-connected impedances in order to make them definite.

From Kirchoff's laws, we obtain

$$V_{ab} = I_{ao}Z_a + I_{ab}Z_b \quad \dots (1)$$

$$V_{bc} = I_{bo}Z_b + I_{oc}Z_c \quad \dots (2)$$

$$V_{ca} = I_{co}Z_c + I_{oa}Z_a \quad \dots (3)$$

$$\text{and } I_{aa} + I_{ba} + I_{co} = 0 \text{ - point law} \quad \dots (4)$$

Equation (1), (3) and (4) can be used for finding  $I_{bo}$ .

Adding (1) and (3), we get

$$\begin{aligned} V_{ab} + V_{ca} &= I_{ao}Z_a + I_{ao}Z_b + I_{co}Z_c + I_{oc}Z_a \\ &= I_{ob}Z_b + I_{co}Z_c + I_{oa}Z_a - I_{oa}Z_a = I_{ob}Z_b + I_{co}Z_c \end{aligned} \quad \dots (5)$$

Substituting  $I_{oa}$  from equation (4) in equation (3), we get

$$V_{ca} = I_{co}Z_c + (I_{bo} + I_{co})Z_a = I_{co}(Z_c + Z_a) + I_{bo}Z_a \quad \dots (6)$$

Putting the value of  $I_{co}$  from equation (5) in equation (6), we have

$$V_{ca} = (Z_c + Z_a) \frac{(V_{ab} + V_{ca}) - I_{ob}Z_b}{Z_c} + I_{bo}Z_a$$

$$V_{ca}Z_c = -I_{ob}Z_bZ_c - I_{ob}Z_bZ_a + I_{bo}Z_aZ_c + V_{ab}Z_a + V_{ab}Z_c + V_{ca}Z_c + V_{ca}Z_a$$

$$\therefore I_{ob} = \frac{(V_{ab} + V_{ca})Z_a + V_{ab}Z_a}{Z_aZ_b + Z_bZ_c + Z_cZ_a}$$

$$\text{Since } V_{ab} + V_{bc} + V_{ca} = 0 \quad \therefore I_{ob} = \frac{V_{ab}Z_c - V_{bc}Z_a}{Z_aZ_b + Z_bZ_c + Z_cZ_a} \quad \dots (7)$$

From the symmetry of the above equation, the expressions for the other branch currents are,

$$I_{oc} = \frac{V_{bc}Z_a - V_{ca}Z_b}{Z_aZ_b + Z_bZ_c + Z_cZ_a} \quad \dots (8) \quad I_{oa} = \frac{V_{ca}Z_b - V_{ab}Z_c}{Z_aZ_b + Z_bZ_c + Z_cZ_a} \quad \dots (9)$$

**Note.** Obviously, the three line currents can be written as

$$I_{ao} = -I_{oa} = \frac{V_{ab}Z_c - V_{ca}Z_b}{\sum Z_aZ_b} \quad \dots (10) \quad I_{bo} = -I_{ob} = \frac{V_{bc}Z_a - V_{ab}Z_c}{\sum Z_aZ_b} \quad \dots (11)$$

$$I_{co} = -I_{oc} = \frac{V_{ca}Z_b - V_{bc}Z_a}{\sum Z_aZ_b} \quad \dots (12)$$

**Example 19.72.** If in the unbalanced Y-connected load of Fig. 19.78,  $Z_a = (10 + j0)$ ,  $Z_b = (3 + j4)$  and  $Z_c = (0 - j10)$  and the load is put across a 3-phase, 200-V circuit with balanced voltages, find the three line currents and voltages across each branch impedance. Assume phase sequence of  $V_{ab}, V_{bc}, V_{ca}$ .

**Solution.** Take  $V_{ab}$  along the axis of reference. The vector expressions for the three voltages

are 
$$V_{ab} = 200 + j0$$

Fig. 19.84

$$V_{bc} = 200 \frac{1}{2} j \frac{\sqrt{3}}{2} = 100 j173.2; \quad V_{ca} = 200 \frac{1}{2} j \frac{\sqrt{3}}{2} = 100 j173.2$$

From equation (9) given above

$$\begin{aligned} I_{oa} &= \frac{(100 - j173.2)(3 - j4) - (200 - j0)(0 - j10)}{(0 - j10)(10 - j0) - (10 - j0)(3 - j4) - (3 - j4)(0 - j10)} \\ &= \frac{-992.8 + j2119.6}{70 - j90} = -20.02 + j4.54 \\ I_{ob} &= \frac{(200 - j0)(0 - j10) - (100 - j173.2)(10 - j0)}{(10 - j0)(3 - j4) - (3 - j4)(0 - j10) - (0 - j10)(10 - j0)} \\ &= \frac{1000 - j268}{70 - j90} = 7.24 + j5.48 \end{aligned}$$

Now,  $I_{oc}$  may also be calculated in the same way or it can be found easily from equation (4) of Art. 19.33.

$$\begin{aligned} \text{Now } I_{oc} &= I_{ao} + I_{bo} = -I_{oa} - I_{ob} = 20.02 - j4.54 - 7.24 - j5.48 = 12.78 - j10.02 \\ V_{oa} &= I_{oa} Z_a = (-20.02 + j4.54)(10 + j0) = 200.2 + j45.4 \\ V_{ob} &= I_{ob} Z_b = (7.24 + j5.48)(3 + j4) = -0.2 + j45.4 \\ V_{oc} &= I_{oc} Z_c = (12.78 - j10.02)(0 - j10) = -100.2 - j127.8 \end{aligned}$$

As a check, we may combine  $V_{oa}$ ,  $V_{ob}$  and  $V_{oc}$  to get the line voltages which should be equal to the applied line voltages. In passing from  $a$  to  $b$  through the circuit internally, we find that we are in opposition to  $V_{oa}$  but in the same direction as the positive direction of  $V_{ob}$ .

$$\begin{aligned} V_{ab} &= V_{ao} - V_{ob} = (200.2 - j45.4) - (-0.2 + j45.4) = 200 - j90.8 \\ V_{bc} &= V_{bo} - V_{oc} = (-0.2 + j45.4) - (-100.2 - j127.8) = 100 + j173.2 \\ V_{ca} &= V_{co} - V_{oa} = (-100.2 - j127.8) - (200.2 + j45.4) = -300.4 - j173.2 \end{aligned}$$

### 19.34. Delta/Star and Star/Delta Conversions

Let us consider the unbalanced  $\Delta$ -connected load of Fig. 19.85 (a) and  $Y$ -connected load of Fig. 19.85 (b). If the two systems are to be equivalent, then the impedances between corresponding pairs of terminals must be the same.

Fig. 19.85

#### (i) Delta/Star Conversion

For  $Y$ -load, total impedance between terminals 1 and 2 is  $Z_1 + Z_2$  (it should be noted that double subscript notation of  $Z_{01}$  and  $Z_{02}$  has been purposely avoided).

Considering terminals 1 and 2 of  $\Delta$ -load, we find that there are two parallel paths having impedances of  $Z_{12}$  and  $(Z_{31} + Z_{23})$ . Hence, the equivalent impedance between terminals 1 and 2 is given by

$$\frac{1}{Z} = \frac{1}{Z_{12}} + \frac{1}{Z_{23} + Z_{31}} \quad \text{or} \quad Z = \frac{Z_{12}(Z_{23} + Z_{31})}{Z_{12} + Z_{23} + Z_{31}}$$

$$\text{Therefore, for equivalence between the two systems } Z_1 + Z_2 = \frac{Z_{12}(Z_{23} + Z_{31})}{Z_{12} + Z_{23} + Z_{31}} \quad \dots (1)$$

$$\text{Similarly } \mathbf{Z}_2 + \mathbf{Z}_3 = \frac{\mathbf{Z}_{23}(\mathbf{Z}_{31} + \mathbf{Z}_{12})}{\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}} \quad \dots (2) \quad \mathbf{Z}_3 + \mathbf{Z}_1 = \frac{\mathbf{Z}_{31}(\mathbf{Z}_{12} + \mathbf{Z}_{23})}{\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}} \quad \dots (3)$$

Adding equation (3) to (1) and subtracting equation (2), we get

$$2\mathbf{Z}_1 = \frac{\mathbf{Z}_{12}(\mathbf{Z}_{23} + \mathbf{Z}_{31}) + \mathbf{Z}_{31}(\mathbf{Z}_{12} + \mathbf{Z}_{23}) - \mathbf{Z}_{23}(\mathbf{Z}_{31} + \mathbf{Z}_{12})}{\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}} = \frac{2\mathbf{Z}_{12}\mathbf{Z}_{31}}{\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}}$$

$$\therefore \mathbf{Z}_1 = \frac{\mathbf{Z}_{12}\mathbf{Z}_{31}}{\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}} \quad \dots (4)$$

The other two results may be written down by changing the subscripts cyclically

$$\therefore \mathbf{Z}_2 = \frac{\mathbf{Z}_{23}\mathbf{Z}_{12}}{\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}}; \quad \dots (5) \quad \mathbf{Z}_3 = \frac{\mathbf{Z}_{31}\mathbf{Z}_{23}}{\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}} \quad \dots (6)$$

The above expression can be easily obtained by remembering that (Art. 2.19)

$$\text{Star } \mathbf{Z} = \frac{\text{Product of } \Delta \mathbf{Z}'\text{'s connected to the same terminals}}{\text{Sum of } \Delta \mathbf{Z}'\text{'s}}$$

It should be noted that all  $\mathbf{Z}'$  are to be expressed in their complex form.

### (iii) Star/Delta Conversion

The equations for this conversion can be obtained by rearranging equations (4), (5) and (6), Rewriting these equations, we get

$$\mathbf{Z}_1(\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}) = \mathbf{Z}_{12}\mathbf{Z}_{31} \quad \dots (7)$$

$$\mathbf{Z}_2(\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}) = \mathbf{Z}_{23}\mathbf{Z}_{12} \quad \dots (8)$$

$$\mathbf{Z}_3(\mathbf{Z}_{12} + \mathbf{Z}_{23} + \mathbf{Z}_{31}) = \mathbf{Z}_{31}\mathbf{Z}_{23} \quad \dots (9)$$

$$\text{Dividing equation (7) by (9), we get } \frac{\mathbf{Z}_1}{\mathbf{Z}_3} = \frac{\mathbf{Z}_{12}}{\mathbf{Z}_{23}} \quad \therefore \mathbf{Z}_{23} = \mathbf{Z}_{12} \frac{\mathbf{Z}_3}{\mathbf{Z}_1}$$

$$\text{Dividing equation (8) by (9), we get } \frac{\mathbf{Z}_2}{\mathbf{Z}_3} = \frac{\mathbf{Z}_{12}}{\mathbf{Z}_{31}} \quad \therefore \mathbf{Z}_{31} = \mathbf{Z}_{12} \frac{\mathbf{Z}_3}{\mathbf{Z}_2}$$

$$\text{Substituting these values in equation (7), we have } \mathbf{Z}_1 \mathbf{Z}_{12} \left( 1 + \frac{\mathbf{Z}_3}{\mathbf{Z}_1} + \frac{\mathbf{Z}_{31}}{\mathbf{Z}_{12}} \right) = \mathbf{Z}_{12}\mathbf{Z}_{12} \frac{\mathbf{Z}_3}{\mathbf{Z}_2} \quad \therefore \mathbf{Z}_1\mathbf{Z}_2 + \mathbf{Z}_2\mathbf{Z}_3 + \mathbf{Z}_3\mathbf{Z}_1 = \mathbf{Z}_{12} \times \mathbf{Z}_3$$

$$\text{or } \mathbf{Z}_1\mathbf{Z}_{12} \left( 1 + \frac{\mathbf{Z}_3}{\mathbf{Z}_1} + \frac{\mathbf{Z}_{31}}{\mathbf{Z}_{12}} \right) = \mathbf{Z}_{12}\mathbf{Z}_{12} \frac{\mathbf{Z}_3}{\mathbf{Z}_2} \quad \therefore \mathbf{Z}_1\mathbf{Z}_2 + \mathbf{Z}_2\mathbf{Z}_3 + \mathbf{Z}_3\mathbf{Z}_1 = \mathbf{Z}_{12} \times \mathbf{Z}_3$$

$$\mathbf{Z}_{12} = \frac{\mathbf{Z}_1\mathbf{Z}_2 + \mathbf{Z}_2\mathbf{Z}_3 + \mathbf{Z}_3\mathbf{Z}_1}{\mathbf{Z}_3} \quad \text{or } \mathbf{Z}_{12} = \mathbf{Z}_1 + \mathbf{Z}_2 + \frac{\mathbf{Z}_1\mathbf{Z}_2}{\mathbf{Z}_3}$$

$$\text{Similarly, } \mathbf{Z}_{23} = \mathbf{Z}_2 + \mathbf{Z}_3 + \frac{\mathbf{Z}_2\mathbf{Z}_3}{\mathbf{Z}_1} = \frac{\mathbf{Z}_1\mathbf{Z}_2 + \mathbf{Z}_2\mathbf{Z}_3 + \mathbf{Z}_3\mathbf{Z}_1}{\mathbf{Z}_1}$$

$$\mathbf{Z}_{31} = \mathbf{Z}_3 + \mathbf{Z}_1 + \frac{\mathbf{Z}_3\mathbf{Z}_1}{\mathbf{Z}_2} = \frac{\mathbf{Z}_1\mathbf{Z}_2 + \mathbf{Z}_2\mathbf{Z}_3 + \mathbf{Z}_3\mathbf{Z}_1}{\mathbf{Z}_2}$$

As in the previous case, it is to be noted that all impedances must be expressed in their complex form.

Another point for noting is that *the line currents of this equivalent delta are the currents in the phases of the Y-connected load.*

**Example 19.73.** An unbalanced star-connected load has branch impedances of  $Z_1 = 10 \angle 30^\circ \Omega$ ,  $Z_2 = 10 \angle -45^\circ \Omega$ ,  $Z_3 = 20 \angle 60^\circ \Omega$  and is connected across a balanced 3-phase, 3-wire supply of 200 V. Find the line currents and the voltage across each impedance using Y/Δ conversion method.

Fig. 19.86

**Solution.** The unbalanced Y-connected load and its equivalent  $\Delta$ -connected load are shown in Fig. 19.86.

$$\text{Now } \mathbf{Z}_1\mathbf{Z}_2 + \mathbf{Z}_2\mathbf{Z}_3 + \mathbf{Z}_3\mathbf{Z}_1 = (10 \angle 30^\circ)(10 \angle -45^\circ) + (10 \angle -45^\circ)(20 \angle 60^\circ) + (20 \angle 60^\circ)(10 \angle 30^\circ) = 100 \angle -15^\circ + 200 \angle 15^\circ + 200 \angle 90^\circ$$

Converting these into their cartesian

form, we get

$$= 100 [\cos(-15^\circ) - j \sin 15^\circ] + 200 (\cos 15^\circ + j \sin 15^\circ) + 200 (\cos 90^\circ + j \sin 90^\circ) \\ = 96.6 - j25.9 + 193.2 + j51.8 + 0 + j200 = 289.8 + j225.9 = 368 \angle 38^\circ$$

$$\mathbf{Z}_{12} = \frac{\mathbf{Z}_1\mathbf{Z}_2 \quad \mathbf{Z}_2\mathbf{Z}_3 \quad \mathbf{Z}_3\mathbf{Z}_1}{\mathbf{Z}_3} \quad \frac{368 \quad 38}{20 \quad 60} \quad 18.4 \quad 22 \quad 17.0 \quad j6.9$$

$$\mathbf{Z}_{23} = \frac{368 \quad 38}{10 \quad 30} \quad 36.8 \quad 8 \quad 36.4 \quad j5.1$$

$$\mathbf{Z}_{31} = \frac{368 \quad 38}{10 \quad 45} \quad 36.8 \quad 83 \quad 4.49 \quad j36.5$$

Assuming clockwise phase sequence of voltages  $\mathbf{V}_{12}$ ,  $\mathbf{V}_{23}$  and  $\mathbf{V}_{31}$ , we have

$$\mathbf{V}_{12} = 200 \quad 0, \quad \mathbf{V}_{23} = 200 \quad 120, \quad \mathbf{V}_{31} = 200 \quad 120$$

$$\mathbf{I}_{12} = \frac{\mathbf{V}_{12}}{\mathbf{Z}_{12}} = \frac{200 \quad 0}{18.4 \quad 22} \quad 10.86 \quad 22 \quad 10.07 \quad j4.06$$

$$\mathbf{I}_{23} = \frac{\mathbf{V}_{23}}{\mathbf{Z}_{23}} = \frac{200 \quad 120}{36.8 \quad 8} \quad 5.44 \quad 128 \quad 3.35 \quad j4.29$$

$$\mathbf{I}_{31} = \frac{\mathbf{V}_{31}}{\mathbf{Z}_{31}} = \frac{200 \quad 120}{36.8 \quad 83} \quad 5.44 \quad 37 \quad 4.34 \quad j3.2$$

$$\text{Line current} = \mathbf{I}'_{11} = \mathbf{I}_{12} + \mathbf{I}_{13} = \mathbf{I}_{12} - \mathbf{I}_{31} \\ = (10.07 + j4.06) - (4.34 + j3.2) = 5.73 + j0.86 = 5.76 \angle 8^\circ 32'$$

$$\mathbf{I}_{22} \quad \mathbf{I}_{23} \quad \mathbf{I}_{12} \quad (3.35 \quad j4.29) \quad (10.07 \quad j4.06) \quad 13.42 \quad j8.35 \quad 15.79 \quad 148 \quad 6$$

$$\mathbf{I}_{33} \quad \mathbf{I}_{31} \quad \mathbf{I}_{23} \quad (4.34 \quad j3.2) \quad (3.35 \quad j4.29) \quad 7.69 \quad j7.49 \quad 10.73 \quad 44 \quad 16$$

These are currents in the *phases of the Y-connected unbalanced load*. Let us find voltage drop across each star-connected branch impedance.

$$\text{Voltage drop across } \mathbf{Z}_1 = \mathbf{V}_{10} = \mathbf{I}_{11} \mathbf{Z}_1 \quad 5.76 \quad 8 \quad 32 \quad .10 \quad 30 \quad 57.6 \quad 38 \quad 32$$

$$\text{Voltage drop across } \mathbf{Z}_2 = \mathbf{V}_{20} = \mathbf{I}_{22} \mathbf{Z}_2 \quad 15.79 \quad 148 \quad 6.10 \quad 45 \quad 157.9 \quad 193 \quad 6$$

$$\text{Voltage drop across } \mathbf{Z}_3 = \mathbf{V}_{30} = \mathbf{I}_{33} \mathbf{Z}_3 \quad 10.73 \quad 44 \quad 16 \quad .20 \quad 60 \quad 214.6 \quad *104 \quad 16$$

**Example 19.74.** A 300-V (line) 3-phase supply feeds a star-connected load consisting of non-inductive resistors of 15, 6 and 10  $\Omega$  connected to the R, Y and B lines respectively. The phase sequence is RYB. Calculate the voltage across each resistor.

**Solution.** The Y-connected unbalanced load and its equivalent  $\Delta$ -connected load are shown in Fig. 19.87. Using Y/ $\Delta$  conversion method we have

$$\begin{aligned} Z_{12} &= \frac{Z_1 Z_2 + Z_2 Z_3 + Z_3 Z_1}{Z_3} \\ &= \frac{90 + 60 + 150}{10} = 30 \Omega \end{aligned}$$

$$Z_{23} = 300/15 = 20$$

$$Z_{31} = 300/6 = 50$$

$$\text{Phase current } I_{RY} = V_{RY} / Z_{12} = 300 / 30 = 10 \text{ A}$$

$$\text{Similarly } I_{YB} = V_{YB} / Z_{23} = 300 / 20 = 15 \text{ A}$$

$$I_{BR} = V_{BR} / Z_{31} = 300 / 50 = 6 \text{ A}$$

Each current is in phase with its own voltage because the load is purely resistive.

The line currents for the delta connection are obtained by compounding these phase currents in pairs, either trigonometrically or by phasor algebra. Using phasor algebra and choosing  $V_{RY}$  as the reference axis, we get

$$I_{RY} = 10 \angle 0^\circ; I_{YB} = 15 \left( \frac{1}{2} - j\frac{\sqrt{3}}{2} \right) = 7.5 - j13.0; I_{BR} = 6 \left( \frac{1}{2} + j\frac{\sqrt{3}}{2} \right) = 3.0 + j5.2$$

Line currents for delta-connection [Fig. 19.66 (b)] are

$$I_R = I_{RY} - I_{BR} = (10 \angle 0^\circ) - (3.0 + j5.2) = 7.0 - j5.2 \text{ or } 14 \text{ A in magnitude}$$

$$I_Y = I_{YB} - I_{RY} = (7.5 - j13.0) - (10 \angle 0^\circ) = -2.5 - j13.0 \text{ or } 13.7 \text{ A in magnitude}$$

$$I_B = I_{BR} - I_{YB} = (3.0 + j5.2) - (7.5 - j13.0) = -4.5 + j18.2 \text{ or } 18.7 \text{ A in magnitude}$$

These line currents for  $\Delta$ -connection are the phase currents for Y-connection. Voltage drop across each limb of Y-connected load is

$$V_{RN} = I_R Z_1 = (7.0 - j5.2)(15 \angle 0^\circ) = 105 - j78 \text{ volt or } 131 \text{ V}$$

$$V_{YN} = I_Y Z_2 = (-2.5 - j13.0)(6 \angle 0^\circ) = -15 - j78 \text{ volt or } 131 \text{ V}$$

$$V_{BN} = I_B Z_3 = (-4.5 + j18.2)(10 \angle 0^\circ) = -45 + j182 \text{ volt or } 187 \text{ V}$$

As a check, it may be verified that the difference of phase voltages taken in pairs should give the three line voltages. Going through the circuit internally, we have

$$V_{RY} = V_{RN} - V_{YN} = (105 - j78) - (-15 - j78) = 120 \angle 0^\circ$$

$$V_{YB} = V_{YN} - V_{BN} = (-15 - j78) - (-45 + j182) = 30 - j260 = 300 \angle -120^\circ$$

$$V_{BR} = V_{BN} - V_{RN} = (-45 + j182) - (105 - j78) = -150 + j260 = 300 \angle 120^\circ$$

This question could have been solved by direct geometrical methods as shown in Ex. 19.52.

**Example 19.75** A Y-connected load is supplied from a 400-V, 3-phase, 3-wire symmetrical system RYB. The branch circuit impedances are

$$Z_R = 10\sqrt{3} + j10; Z_Y = 20 + j20\sqrt{3}; Z_B = 0 - j10$$

Determine the current in each branch. Phase sequence is RYB.

(Network Analysis, Nagpur Univ. 1993)

Fig. 19.87

**Solution.** The circuit is shown in Fig. 19.88. The problem will be solved by using all the four possible ways in which 3-wire unbalanced Y connected load can be handled.

$$\text{Now, } \mathbf{Z}_R \quad 20 \quad 30 \quad (17.32 \quad j10)$$

$$\mathbf{Z}_Y \quad 40 \quad 60 \quad (20 \quad j34.64)$$

$$\mathbf{Z}_B = 10 \angle -90^\circ = -j10$$

$$\text{Also, let } \mathbf{V}_{RY} \quad 400 \quad 0 \quad 400 \quad j0$$

$$\mathbf{V}_{RB} = 400 \angle -120^\circ = -200 - j346$$

$$\mathbf{V}_R = 400 \angle 120^\circ = -200 + j346$$

Fig. 19.88

**(a) By applying Kirchoff's Laws**

With reference to Art. 19.33, it is seen that

$$\mathbf{I}_{RO} = \mathbf{I}_R = \frac{\mathbf{V}_{RY}\mathbf{Z}_B - \mathbf{V}_{BR}\mathbf{Z}_Y}{\mathbf{Z}_R\mathbf{Z}_Y + \mathbf{Z}_Y\mathbf{Z}_B + \mathbf{Z}_B\mathbf{Z}_R}; \mathbf{I}_{YO} = \mathbf{I}_Y = \frac{\mathbf{V}_{YB}\mathbf{Z}_R - \mathbf{V}_{RY}\mathbf{Z}_B}{\mathbf{Z}_R\mathbf{Z}_Y + \mathbf{Z}_Y\mathbf{Z}_B + \mathbf{Z}_B\mathbf{Z}_R};$$

$$\mathbf{I}_{BO} = \mathbf{I}_B = \frac{\mathbf{V}_{BR}\mathbf{Z}_Y - \mathbf{V}_{YB}\mathbf{Z}_R}{\mathbf{Z}_R\mathbf{Z}_Y + \mathbf{Z}_Y\mathbf{Z}_B + \mathbf{Z}_B\mathbf{Z}_R}$$

$$\text{Now, } \mathbf{Z}_R\mathbf{Z}_Y + \mathbf{Z}_Y\mathbf{Z}_B + \mathbf{Z}_B\mathbf{Z}_R$$

$$= 20 \angle 30^\circ \cdot 40 \angle 60^\circ + 40 \angle 60^\circ \cdot 10 \angle -90^\circ + 10 \angle -90^\circ \cdot 20 \angle 30^\circ$$

$$= 800 \angle 90^\circ + 400 \angle -30^\circ + 200 \angle -60^\circ = 446 + j426 = 617 \angle 43.7^\circ$$

$$\mathbf{V}_{RY}\mathbf{Z}_B \quad \mathbf{V}_{BR}\mathbf{Z}_Y \quad 400 \quad 10 \quad 90 \quad 400 \quad 120 \quad 40 \quad 60$$

$$= 16,000 - j4000 = 16,490 \angle -14^\circ 3'$$

$$\therefore \mathbf{I}_R \quad \frac{16,490 \quad 14 \quad 3}{617 \quad 43.7} \quad 26.73 \quad 57 \quad 45$$

$$\mathbf{V}_{YB}\mathbf{Z}_R \quad \mathbf{V}_{RY}\mathbf{Z}_B \quad 400 \quad 120 \quad 20 \quad 30 \quad 400 \quad 10 \quad 90 \quad j4000 \quad 4000 \quad 90$$

$$\mathbf{I}_Y \quad \frac{4000 \quad 90}{617 \quad 43.7} \quad 6.48 \quad 133.7$$

$$\mathbf{V}_{BR}\mathbf{Z}_Y \quad \mathbf{V}_{YB}\mathbf{Z}_R \quad 400 \quad 120 \quad 40 \quad 60 \quad 400 \quad 120 \quad 20 \quad 30$$

$$= -16,000 + j8,000 = 17,890 \angle 153^\circ 26'$$

$$\therefore \mathbf{I}_B \quad \frac{17,890 \quad 153 \quad 26}{617 \quad 43.7} \quad 29 \quad 109 \quad 45$$

**(b) By Star/Delta Conversion (Fig. 19.89)**

The given star may be converted into the equivalent delta with the help of equations given in Art. 19.34.

$$\mathbf{Z}_{RY} \quad \frac{\mathbf{Z}_R\mathbf{Z}_Y \quad \mathbf{Z}_Y\mathbf{Z}_B \quad \mathbf{Z}_B\mathbf{Z}_R}{\mathbf{Z}_B} \quad \frac{617 \quad 43.7}{10 \quad 90} \quad 61.73 \quad 133.7$$

$$\mathbf{Z}_{YB} \quad \frac{\Sigma\mathbf{Z}_R\mathbf{Z}_Y}{\mathbf{Z}_R} \quad \frac{617 \quad 43.7}{20 \quad 30} \quad 30.87 \quad 13.7$$

$$\mathbf{Z}_{BR} \quad \frac{\Sigma\mathbf{Z}_R\mathbf{Z}_Y}{\mathbf{Z}_Y} \quad \frac{617 \quad 43.7}{40 \quad 60} \quad 15.43 \quad 16.3$$

$$\mathbf{I}_{RY} \quad \frac{\mathbf{V}_{RY}}{\mathbf{Z}_{RY}} \quad \frac{400}{61.73 \quad 133.7} \quad 6.48 \quad 133.7 \quad (4.47 \quad j4.68)$$

Fig. 19.89

$$\mathbf{I}_{YB} = \frac{\mathbf{V}_{YB}}{\mathbf{Z}_{YB}} = \frac{400}{30.87} \frac{120}{13.7} = 12.95 \angle 133.7^\circ = (8.95 - j9.35)$$

$$\mathbf{I}_{BR} = \frac{\mathbf{V}_{BR}}{\mathbf{Z}_{BR}} = \frac{400}{15.43} \frac{120}{16.3} = 25.9 \angle 136.3^\circ = (18.7 - j17.9)$$

$$\mathbf{I}_{RR} \quad \mathbf{I}_{RY} \quad \mathbf{I}_{BR} \quad 14.23 \quad j22.58 \quad 26.7 \quad 57.48$$

$$\mathbf{I}_{YY} \quad \mathbf{I}_{YB} \quad \mathbf{I}_{RY} \quad 4.48 \quad j4.67 \quad 6.47 \quad 134.6$$

$$\mathbf{I}_{YB} \quad \mathbf{I}_{BR} \quad \mathbf{I}_{YB} \quad 9.85 \quad j27.25 \quad 29 \quad 109.48$$

$$\mathbf{I} = (0 + j0) \quad \text{— as a check}$$

As explained in Art. 19.34, these line currents of the equivalent delta represent the phase currents of the star-connected load of Fig. 19.89 (a).

**Note.** Minor differences are due to accumulated errors.

**(c) By Using Maxwell's Loop Current Method**

Let the loop or mesh currents be as shown in Fig. 19.90. It may be noted that

$$\mathbf{I}_R = \mathbf{I}_1; \mathbf{I}_Y = \mathbf{I}_2 - \mathbf{I}_1 \text{ and } \mathbf{I}_B = -\mathbf{I}_2$$

Considering the drops across R and Y-arms, we get

$$\mathbf{I}_1 \mathbf{Z}_R + \mathbf{Z}_Y (\mathbf{I}_1 - \mathbf{I}_2) = \mathbf{V}_{RY} \quad \dots (i)$$

or

$$\mathbf{I}_1 (\mathbf{Z}_R + \mathbf{Z}_Y) - \mathbf{I}_2 \mathbf{Z}_Y = \mathbf{V}_{RY} \quad \dots (i)$$

Similarly, considering the legs Y and B, we have

$$\mathbf{Z}_Y (\mathbf{I}_2 - \mathbf{I}_1) + \mathbf{Z}_B \mathbf{I}_2 = \mathbf{V}_{YB}$$

or

$$-\mathbf{I}_1 \mathbf{Z}_Y + \mathbf{I}_2 (\mathbf{Z}_B + \mathbf{Z}_Y) = \mathbf{V}_{YB} \quad \dots (ii)$$

Solving for  $\mathbf{I}_1$  and  $\mathbf{I}_2$ , we get

$$\mathbf{I}_1 = \frac{\mathbf{V}_{RY} (\mathbf{Z}_Y + \mathbf{Z}_B) + \mathbf{Z}_{YB} \mathbf{V}_Y}{(\mathbf{Z}_R + \mathbf{Z}_Y) (\mathbf{Z}_Y + \mathbf{Z}_B) - \mathbf{Z}_Y^2};$$

$$\mathbf{I}_2 = \frac{\mathbf{V}_{YB} (\mathbf{Z}_R + \mathbf{Z}_Y) + \mathbf{V}_{RY} \mathbf{Z}_Y}{(\mathbf{Z}_R + \mathbf{Z}_Y) (\mathbf{Z}_Y + \mathbf{Z}_B) - \mathbf{Z}_Y^2}$$

$$\begin{aligned} \mathbf{I}_1 &= \frac{400(20 - j24.64) + 400 \cdot 120 \cdot 40 \cdot 60}{(37.32 - j44.64)(20 + j24.64) - 1600 \cdot 120} \\ &= \frac{16,000 - j4,000}{448 + j427} = \frac{16,490 \angle -14^\circ 3'}{617 \angle 43.7^\circ} \\ &= 26 \angle -57^\circ 45' = (13.9 - j22) \end{aligned}$$

Fig. 19.90

$$\begin{aligned} \mathbf{I}_2 &= \frac{(200 - j346)(37.32 - j44.64) - 400(20 - j34.64)}{484 - j427} \\ &= \frac{16,000 - j8,000}{448 + j427} = \frac{17,890 \angle -26^\circ 34'}{617 \angle 43.7^\circ} = 28.4 \angle -70^\circ 16' \\ &= 28.4 \angle -70^\circ 16' = (9.55 - j26.7) \end{aligned}$$

$$\begin{aligned} \therefore \mathbf{I}_R &= \mathbf{I}_1 - \mathbf{I}_2 = 26 - 57 - j45 \\ \mathbf{I}_Y &= \mathbf{I}_2 - \mathbf{I}_1 = (9.55 - j26.7) - (13.9 - j22) = 4.35 - j4.7 = 6.5 \angle 134^\circ \\ \mathbf{I}_B &= \mathbf{I}_2 - \mathbf{I}_1 = 28.4 - 70 - j16 = 28.4 \angle 109.44^\circ \end{aligned}$$

**(d) By Using Millman's Theorem\***

According to this theorem, the voltage of the load star point  $O'$  with respect to the star point or neutral  $O$  of the generator or supply (normally zero potential) is given by

$$\mathbf{V}_{O'O} = \frac{\mathbf{V}_{RO}\mathbf{Y}_R + \mathbf{V}_{YO}\mathbf{Y}_Y + \mathbf{V}_{BO}\mathbf{Y}_B}{\mathbf{Y}_R + \mathbf{Y}_Y + \mathbf{Y}_B}$$

Fig. 19.91

where  $\mathbf{V}_{RO}$ ,  $\mathbf{V}_{YO}$  and  $\mathbf{V}_{BO}$  are the phase voltages of the generator or 3-phase supply.

As seen from Fig. 19.91, voltage across each phase of the load is

$$\mathbf{V}_{RO'} = \mathbf{V}_{RO} - \mathbf{V}_{O'O} \quad \mathbf{V}_{YO'} = \mathbf{V}_{YO} - \mathbf{V}_{O'O} \quad \mathbf{V}_{BO'} = \mathbf{V}_{BO} - \mathbf{V}_{O'O}$$

Obviously,  $\mathbf{I}_{RO'} = (\mathbf{V}_{RO} - \mathbf{V}_{O'O})\mathbf{Y}_R$ ;  $\mathbf{I}_{YO'} = (\mathbf{V}_{YO} - \mathbf{V}_{O'O})\mathbf{Y}_Y$  and

$$\mathbf{I}_{BO'} = (\mathbf{V}_{BO} - \mathbf{V}_{O'O})\mathbf{Y}_B$$

$$\text{Here } \mathbf{Y}_R = \frac{1}{20 - j30} = 0.05 + j0.03 \quad (0.0433 - j0.025)$$

$$\mathbf{Y}_Y = \frac{1}{40 - j60} = 0.025 + j0.0375 \quad (0.0125 - j0.0217)$$

$$\mathbf{Y}_B = \frac{1}{10 - j90} = 0.1 + j0.09 \quad (0.1 - j0.09)$$

\* Incidentally, it may be noted that the p.d. between load neutral and supply neutral is given by

$$\mathbf{V}_{O'O} = \frac{\mathbf{V}_{RO'} + \mathbf{V}_{YO'} + \mathbf{V}_{BO'}}{3}$$

$$\therefore \mathbf{Y}_R \ \mathbf{Y}_Y \ \mathbf{Y}_B \quad 0.0558 \quad j0.0533 \quad 0.077 \quad 43.7$$

$$\text{Let} \quad \mathbf{V}_{RO} = \frac{400}{\sqrt{3}} \quad 0 \quad (231 \quad j0)$$

$$\mathbf{V}_{BO} = 231 \quad 120 \quad 115.5 \quad j200$$

$$\mathbf{V}_{BO} = 231 \quad 120 \quad 115.5 \quad j200$$

$$\mathbf{V}_{OO} = \frac{231.0.05 \quad 30 \quad 231 \quad 120 \quad .025 \quad 60 \quad 231 \quad 120 \quad .01 \quad 90}{0.077 \quad 43.7}$$

$$= \frac{-15.8 - j17.32}{0.077 \angle 43.7^\circ} = \frac{23.5 \angle -132.4^\circ}{0.077 \angle 43.7^\circ} = 305 \angle -176.1^\circ = (304.5 - j20.8)$$

$$\mathbf{V}_{RO} \quad \mathbf{V}_{RO} \quad \mathbf{V}_{OO} \quad 231 \quad (304.5 \quad j20.8) \quad 535.5 \quad j20.8 \quad 536 \quad 2.2$$

$$\mathbf{V}_{YO} \quad (115.5 \quad j200) \quad (304.5 \quad j20.8) \quad 189 \quad j179 \quad 260 \quad 43 \quad 27$$

$$\mathbf{V}_{BO} \quad (115.5 \quad j200) \quad (304.5 \quad j20.8) \quad 189 \quad j221 \quad 291 \quad 49 \quad 27$$

$$\therefore \mathbf{I}_{RO} \quad 536 \quad 2.2 \quad 0.05 \quad 30 \quad 26.5 \quad 27.8$$

$$\mathbf{I}_{YO} \quad 260 \quad 43 \quad 27 \quad 0.025 \quad 60 \quad 6.5 \quad 103 \quad 27$$

$$\mathbf{I}_{BO} \quad 291 \quad 49 \quad 27 \quad 0.1 \quad 90 \quad 29.1 \quad 139 \quad 27$$

**Note.** As seen from above,  $\mathbf{V}'_{RO} = \mathbf{V}'_{RO} - \mathbf{V}'_{OO}$

Substituting the value of  $\mathbf{V}'_{OO}$ , we have

$$\begin{aligned} \mathbf{V}_{RO} &= \mathbf{V}_{RO} - \frac{\mathbf{V}_{RO} \mathbf{Y}_R + \mathbf{V}_{YO} \mathbf{Y}_Y + \mathbf{V}_{BO} \mathbf{Y}_B}{\mathbf{Y}_R + \mathbf{Y}_Y + \mathbf{Y}_B} \\ &= \frac{(\mathbf{V}_{RO} - \mathbf{V}_{YO}) \mathbf{Y}_Y + (\mathbf{V}_{RO} - \mathbf{V}_{BO}) \mathbf{Y}_B}{\mathbf{Y}_R + \mathbf{Y}_Y + \mathbf{Y}_B} \\ &= \frac{\mathbf{V}_{RY} \mathbf{Y}_Y + \mathbf{V}_{RB} \mathbf{Y}_B}{\mathbf{Y}_R + \mathbf{Y}_Y + \mathbf{Y}_B} \end{aligned}$$

Since  $\mathbf{V}_{RO}$  is taken as the reference vector, then as seen from Fig. 19.92.

$$\mathbf{V}_{RY} \quad 400 \quad 30 \quad \text{and} \quad \mathbf{V}_{RB} \quad 400 \quad 30$$

$$\therefore \mathbf{V}_{RO} = \frac{400 \quad 30 \quad 0.025 \quad 60 \quad 400 \quad 30 \quad 0.1 \quad 90}{0.077 \quad 43.7}$$

$$= \frac{28.6 + j29.64}{0.077 \angle 43.7^\circ} = \frac{41 \angle 46^\circ}{0.077 \angle 43.7^\circ} = 532.5 \angle 2.3^\circ$$

$$\mathbf{I}_{RO} \quad \mathbf{V}_{RO} \mathbf{Y}_R \quad 532.5 \quad 2.3 \quad 0.05 \quad 30 \quad 26.6 \quad 27.7$$

Similarly,  $\mathbf{V}_{YO}$  and  $\mathbf{V}_{BO}$  may be found and  $\mathbf{I}_Y$  and  $\mathbf{I}_B$  calculated therefrom.

**Example 19.76.** Three impedances,  $Z_R$ ,  $Z_Y$  and  $Z_B$  are connected in star across a 440-V, 3-phase supply. If the voltage of star-point relative to the supply neutral is  $200 \angle 150^\circ$  volt and Y and B line currents are  $10 \angle -90^\circ$  A and  $20 \angle 90^\circ$  A respectively, all with respect to the voltage between the supply neutral and the R line, calculate the values of  $Z_R$ ,  $Z_Y$  and  $Z_B$

(Elect Circuit; Nagpur Univ. 1991)

Fig. 19.92

**Solution.** Let  $O$  and  $O'$  be the supply and load neutrals respectively. Also, let,

$$\mathbf{V}_{RO} = \frac{440}{\sqrt{3}} \quad 0 \quad 254 \quad 0 \quad 254 \quad j0$$

$$\mathbf{V}_{YO} = 254 \quad 120 \quad 127 \quad j220$$

$$\mathbf{V}_{BO} = 254 \quad 120 \quad 127 \quad j220$$

$$\mathbf{I}_Y = 10 \angle -90^\circ = -j10; \quad \mathbf{I}_B = 20 \angle 90^\circ = j20$$

$$\mathbf{I}_R = -(\mathbf{I}_Y + \mathbf{I}_B) = -j10$$

$$\text{Also, } \mathbf{V}_{OO} = 200 \quad 150 \quad 173 \quad j100$$

$$\mathbf{V}_{RO} \quad \mathbf{V}_{OO} \quad 254 \quad (173 \quad j100) \quad 427 \quad j100 \quad 438.5 \quad 13.2$$

$$\mathbf{V}_{YO} \quad \mathbf{V}_{OO} \quad (127 \quad j220) \quad (173 \quad j100) \quad 46 \quad j320 \quad 323 \quad 81.6$$

$$\mathbf{V}_{BO} \quad \mathbf{V}_{OO} \quad (127 \quad j220) \quad (173 \quad j100) \quad 46 \quad j120 \quad 128.6 \quad 69$$

As seen from Art. 19.32.

$$\mathbf{Z}_R = \frac{\mathbf{V}_{RO} \quad \mathbf{V}_{OO}}{\mathbf{I}_R} = \frac{438.5 \quad 13.2}{10 \quad 90} = 43.85 \quad 76.8$$

$$\mathbf{Z}_Y = \frac{\mathbf{V}_{YO} \quad \mathbf{V}_{OO}}{\mathbf{I}_Y} = \frac{323}{10 \quad 90} = 32.3 \quad 8.4$$

$$\mathbf{Z}_B = \frac{\mathbf{V}_{BO} \quad \mathbf{V}_{OO}}{\mathbf{I}_B} = \frac{128.6 \quad 69}{20 \quad 90} = 6.43 \quad 21$$

Fig. 19.93

### 19.35. Unbalanced Star-connected Non-inductive Load

Such a case can be easily solved by direct geometrical method. If the supply system is symmetrical, the line voltage vectors can be drawn in the form of an equilateral triangle  $RYB$  (Fig. 19.94). As the load is an unbalanced one, its neutral point will not, obviously, coincide with the centre of the gravity or centroid of the triangle. Let it lie at any other point like  $N$ . If point  $N$  represents the potential of the neutral point if the unbalanced load, then vectors drawn from  $N$  to points,  $R$ ,  $Y$  and  $B$  represent the voltages across the branches of the load. These voltages can be represented in their rectangular co-ordinates with respect to the rectangular axis drawn through  $N$ . It is seen that taking co-ordinates of  $N$  as  $(0, 0)$ , the co-ordinates of point  $R$  are  $[(V/2 - x), -y]$

of point  $Y$  are  $[-(V/2 + x), -y]$

and of point  $B$  are  $[-x, (\sqrt{3}V/2 - y)]$

$$\mathbf{V}_{RN} = \frac{V}{2} - x \quad -y; \quad \mathbf{V}_{YN} = \frac{V}{2} + x \quad -y$$

$$\mathbf{V}_{BN} = x \quad j \frac{\sqrt{3}V}{2} - y$$

Fig. 19.94

Let  $R_1$ ,  $R_2$  and  $R_3$  be the respective branch impedances,  $Y_1$ ,  $Y_2$  and  $Y_3$  the respective admittances and  $\mathbf{I}_R$ ,  $\mathbf{I}_Y$  and  $\mathbf{I}_B$  the respective currents in them.

Then

$$\mathbf{I}_R = \mathbf{V}_{RN} / \mathbf{R}_1 = \mathbf{V}_{RN} \mathbf{Y}_1$$

Similarly,

$$\mathbf{I}_Y = \mathbf{V}_{YN} \mathbf{Y}_2 \text{ and } \mathbf{I}_B = \mathbf{V}_{BN} \mathbf{Y}_3. \text{ Since } \mathbf{I}_R + \mathbf{I}_Y + \mathbf{I}_B = 0$$

$\therefore$

$$\mathbf{V}_{RN} \mathbf{Y}_1 + \mathbf{V}_{YN} \mathbf{Y}_2 + \mathbf{V}_{BN} \mathbf{Y}_3 = 0$$

$$\text{or } Y_1 \frac{V}{2} x - jy Y_2 \frac{V}{2} x - jy Y_3 x + j \frac{\sqrt{3}V}{2} y = 0$$

$$\text{or } x(Y_1 - Y_2 - Y_3) - \frac{V}{2}(Y_1 - Y_2) - j Y_3 \frac{\sqrt{3}V}{2} - y(Y_1 - Y_2 - Y_3) = 0$$

$$\therefore -x(Y_1 + Y_2 + Y_3) + \frac{V}{2}(Y_1 - Y_2) = 0 \quad \therefore x = \frac{V(Y_1 - Y_2)}{2Y_1 + Y_2 + Y_3}$$

$$\text{Also } Y_3 \frac{\sqrt{3}V}{2} - y(Y_1 + Y_2 + Y_3) = 0 \quad \therefore y = \frac{\sqrt{3}V}{2} \frac{Y_3}{(Y_1 + Y_2 + Y_3)}$$

Knowing the values of  $x$ , the values of  $\mathbf{V}_{RN}$ ,  $\mathbf{V}_{YN}$  and  $\mathbf{V}_{BN}$  and hence, of  $\mathbf{I}_R$ ,  $\mathbf{I}_Y$  and  $\mathbf{I}_B$  can be found as illustrated by Ex. 19.68.

**Example 19.77.** Three non-inductive resistances of 5, 10 and 15  $\Omega$  are connected in star and supplied from a 230-V symmetrical 3-phase system. Calculate the line currents (magnitudes). (Principles of Elect. Engg. Jadavpur Univ.)

**Solution.**

(a) Star/Delta Conversion Method

The Y-connected unbalanced load and its equivalent  $\Delta$ -connected load are shown in Fig. 19.95 (a) and (b) respectively. Using Y/ $\Delta$  conversion, we have

$$\mathbf{Z}_{12} = \frac{\mathbf{Z}_1 \mathbf{Z}_2 + \mathbf{Z}_2 \mathbf{Z}_3 + \mathbf{Z}_3 \mathbf{Z}_1}{\mathbf{Z}_3} = \frac{50 + 150 + 75}{15} = \frac{55}{3}$$

$$\mathbf{Z}_{23} = \frac{275}{5} = 55 \text{ and } \mathbf{Z}_{31} = \frac{275}{10} = 27.5$$

$$\text{Phase current } \mathbf{I}_{RY} = \mathbf{V}_{RY} / \mathbf{Z}_{12} = 230 / (55/3) = 12.56 \text{ A}$$

$$\text{Similarly, } \mathbf{I}_{YB} = \mathbf{V}_{YB} / \mathbf{Z}_{23} = 230 / 55 = 4.18 \text{ A; } \mathbf{I}_{BR} = \mathbf{V}_{BR} / \mathbf{Z}_{31} = 230 / 27.5 = 8.36 \text{ A}$$

The line currents for  $\Delta$ -connection are obtained by compounding the above phase currents trigonometrically or vectorially. Choosing vector addition and taking  $\mathbf{V}_{RY}$  as the reference vector, we get;

$$\mathbf{I}_{RY} = (12.56 + j0)$$

$$\mathbf{I}_{YB} = 4.18 \frac{1}{2} j \frac{\sqrt{3}}{2} = -2.09 - j3.62$$

$$\mathbf{I}_{BR} = 8.36 \frac{1}{2} j \frac{\sqrt{3}}{2} = -4.18 + j7.24$$

Fig. 19.95

Hence, line currents for  $\Delta$ -connection of Fig. 19.95 (b) are

$$\begin{aligned} \mathbf{I}_R &= \mathbf{I}_{RY} + \mathbf{I}_{RB} = \mathbf{I}_{RY} - \mathbf{I}_{BR} \\ &= (12.56 + j0) - (-4.18 + j7.24) = 16.74 - j7.24 \text{ or } 18.25 \text{ A - in magnitude} \end{aligned}$$

$$\begin{aligned} \mathbf{I}_Y &= \mathbf{I}_{YR} + \mathbf{I}_{YB} = \mathbf{I}_{YB} - \mathbf{I}_{RY} \\ &= (-2.09 - j3.62) - (12.56 + j0) = -14.65 - j3.62 \text{ or } 15.08 \text{ A - in magnitude} \end{aligned}$$

$$\begin{aligned} \mathbf{I}_B &= \mathbf{I}_{BR} + \mathbf{I}_{BY} = \mathbf{I}_{BR} - \mathbf{I}_{YB} \\ &= (-4.18 + j7.24) - (-2.09 - j3.62) = -2.09 + j10.86 \text{ or } 11.06 \text{ A - in magnitude} \end{aligned}$$

**(b) Geometrical Method**

Here,  $R_1 = 5 \Omega$ ,  $R_2 = 10 \Omega$ ; and  $R_3 = 15 \Omega$ ;  $Y_1 = 1/5S$ ;  $Y_2 = 1/10S$ ;  $Y_3 = 1/15S$

As found above in Art. 19.35  $x = \frac{V}{2}(Y_1 - Y_2)/(Y_1 + Y_2 + Y_3)$

$$= \frac{230}{2} \frac{1}{5} \frac{1}{10} \bigg/ \frac{1}{5} \frac{1}{10} \frac{1}{15} = 31.4$$

$$y = \frac{\sqrt{3}V}{2} \cdot Y_3 \bigg/ (Y_1 + Y_2 + Y_3) = \frac{(\sqrt{3} \cdot 115 \cdot 1/15)}{(11/30)} = 36.2$$

$$V_{RN} = \frac{V}{2} x - jy = (115 \cdot 31.4) - j36.2 = 83.6 - j36.2$$

$$V_{YN} = \frac{V}{2} x + jy = 146.4 + j36.2$$

$$V_{BN} = x + j \frac{\sqrt{3}V}{2} y = 31.4 + j163$$

$$I_R = \frac{V_{RN}}{R_1} = \frac{(83.6 - j36.2)}{5} = 16.72 - j7.24$$

$$I_Y = \frac{V_{YN}}{R_2} = \frac{(146.4 + j36.2)}{10} = 14.64 + j3.62$$

$$I_B = \frac{V_{BN}}{R_3} = \frac{(31.4 + j163)}{15} = 2.1 + j10.9$$

These are the same currents as found before.

**(c) Solution by Millman's Theorem**

$Y_R = 1/5 \Omega^{-1}$ ;  $Y_Y = 1/10 \Omega^{-1}$ ;  $Y_B = 1/15 \Omega^{-1}$  and  $Y_R + Y_Y + Y_B = 11/30 \Omega^{-1}$  Siemens

Let the supply voltages be represented (Fig. 19.96) by

$$V_{RO} = 230/\sqrt{3} \angle 0^\circ; V_{YO} = 133 \angle -120^\circ; V_{BO} = 133 \angle 120^\circ$$

Fig. 19.96

The p.d. between load and supply neutral is

$$\begin{aligned} V_{OO'} &= \frac{133/5 \angle 0^\circ + (133/10) \angle -120^\circ + 120 \angle 120^\circ}{30/11} \\ &= 42.3 - j10.4 = 43.6 \angle -13.8^\circ \end{aligned}$$

$$\begin{aligned} \mathbf{V}_{RO} &= 133 \quad (42.3 \quad j10.4) \quad 90.7 \quad j10.4 \\ \mathbf{V}_{YO} &= 133 \quad 120 \quad (42.3j \quad 10.4) \\ &= (-66.5 - j115) - (42.3 - j10.4) = -108.8 - j104.6 \\ \mathbf{V}_{BO} &= 133 \quad 120 \quad V_{OO} \quad (66.5 \quad j115) \quad (42.3 \quad j10.4) \quad 108.8 \quad j125.4 \\ \mathbf{I}_R &= \frac{\mathbf{V}_{RO}}{\mathbf{Z}_R} = \frac{1/5 \cdot (90.7 \quad j10.4)}{18.1} = j2.1 \text{ or } 18.22 \text{ A in magnitude} \\ \mathbf{I}_Y &= 10.88 \quad j10.5 \text{ or } 15.1 \text{ A in magnitude} \\ \mathbf{I}_B &= -7.5 + j8.4 \text{ or } 11.7 \text{ A in magnitude} \end{aligned}$$

**Example 19.78.** The unbalanced circuit of Fig. 19.97 (a) is connected across a symmetrical 3-phase supply of 400-V. Calculate the currents and phase voltages. Phase sequence is RYB.

**Solution.** The line voltages are represented by the sides of an equilateral triangle ABC in Fig. 19.97 (b). Since phase impedances are unequal, phase voltages are unequal and are represented by lengths, NA, NB and NC where N is the neutral point which is shifted from its usual position. CM and ND are drawn perpendicular to horizontal side AB. Let co-ordinates of point N be (0, 0). Obviously, AM = BM = 200 V, CM =  $\sqrt{3} \times 200$  V, CM =  $\sqrt{3} \times 200 = 346$  V. Let DM = x volts and ND = y volts.

Fig. 19.97

Then, with reference to point N, the vector expressions for phase voltages are

$$\begin{aligned} \mathbf{V}_R &= (200 - x) - jy, \quad \mathbf{V}_Y = (200 - x) - jy, \quad \mathbf{V}_B = x - j(346 - y) \\ \mathbf{I}_R &= \frac{\mathbf{V}_R}{\mathbf{Z}_R} = \frac{(200 - x) - jy}{3 - j4} = \frac{3 + j4}{3 - j4} (24 - 0.12x - 0.16y) = j(32 - 0.16x - 0.12y) \\ \mathbf{I}_Y &= \frac{\mathbf{V}_Y}{\mathbf{Z}_Y} = \frac{(200 - x) - jy}{6 - j8} = \frac{6 + j8}{6 - j8} (-12 - 0.06x - 0.08y) + j(16 + 0.08x - 0.06y) \\ \mathbf{I}_B &= \frac{\mathbf{V}_B}{\mathbf{Z}_B} = \frac{x - j(346 - y)}{8 - j6} = \frac{8 + j6}{8 - j6} (20.76 - 0.08x - 0.06y) + j(27.68 + 0.06x - 0.08y) \end{aligned}$$

Now,  $\mathbf{I}_R + \mathbf{I}_Y + \mathbf{I}_B = 0$

$$\therefore (32.76 - 0.26x - 0.3y) + j(11.68 + 0.3x - 0.26y) = 0$$

Obviously, the real component as well as the *j*-component must be zero.

$$\therefore 32.76 - 0.26x - 0.3y = 0 \quad \text{and} \quad 11.68 + 0.3x - 0.26y = 0$$

Solving these equations for *x* and *y*, we have *x* = 31.9 V and *y* = 81.6 V

$$\begin{aligned} \mathbf{V}_R &= (200 - 31.9) - j81.6 = 168 - j81.6 = 186.7 \quad 25.9 \\ \mathbf{V}_Y &= (200 - 31.9) - j81.6 = 231.9 - j81.6 = 245.8 \quad 199.4 \\ \mathbf{V}_B &= 31.9 - j(346 - 81.6) = 31.9 - j264.4 = 266.3 \quad 83.1 \end{aligned}$$

Substituting these values of *x* and *y* in the expressions for currents, we get

$$\mathbf{I}_R \begin{pmatrix} 24 & 0.12 & 31.9 & 0.16 & 81.6 \end{pmatrix} j \begin{pmatrix} 32 & 0.16 & 31.9 & 0.12 & 81.6 \end{pmatrix}$$

$$= 7.12 - j36.7$$

$$\text{Similarly } \mathbf{I}_Y \begin{pmatrix} 20.44 & j13.65 \end{pmatrix}; \mathbf{I}_B \begin{pmatrix} 13.3 & j23.06 \end{pmatrix}$$

$$\Sigma \mathbf{I} = (0. + j0) \text{ - as a check}$$

**Example 19.79.** A 3- $\phi$ , 4-wire, 400-V symmetrical system supplies a Y-connected load having following branch impedances:

$$Z_R = 100\Omega, Z_Y = j10\Omega \text{ and } Z_B = -j10\Omega$$

Compute the values of load phase voltages and currents and neutral current. Phase sequence is RYB.

How will these values change in the event of an open in the neutral wire?

**Solution. (a) When Neutral Wire is Intact.** [Fig 19.98 (a)]. As discussed in Art. 19.30, the load phase voltages would be the same as supply phase voltages despite imbalance in the load. The three load phase voltages are:

$$\mathbf{V}_R \begin{pmatrix} 231 & 0 \end{pmatrix}, \mathbf{V}_Y \begin{pmatrix} 231 & 120 \end{pmatrix} \text{ and } \mathbf{V}_B \begin{pmatrix} 231 & 120 \end{pmatrix}$$

$$\mathbf{I}_R \begin{pmatrix} 231 & 0 \end{pmatrix} / 100 \begin{pmatrix} 0 \end{pmatrix} = 2.31 \begin{pmatrix} 0 \end{pmatrix} = 2.31 \begin{pmatrix} j0 \end{pmatrix}$$

$$\mathbf{I}_Y \begin{pmatrix} 231 & 120 \end{pmatrix} / 10 \begin{pmatrix} 90 \end{pmatrix} = 2.31 \begin{pmatrix} 210 \end{pmatrix} = 20 \begin{pmatrix} j11.5 \end{pmatrix}$$

$$\mathbf{I}_B \begin{pmatrix} 231 & 120 \end{pmatrix} / 10 \begin{pmatrix} 90 \end{pmatrix} = 23.1 \begin{pmatrix} 210 \end{pmatrix} = 20 \begin{pmatrix} j11.5 \end{pmatrix}$$

$$\mathbf{I}_N \begin{pmatrix} \mathbf{I}_R & \mathbf{I}_Y & \mathbf{I}_B \end{pmatrix} = \begin{pmatrix} 2.31 & 20 & j11.5 & 20 & j11.5 \end{pmatrix} = 37.7 \text{ A}$$

**(b) When Neutral is Open** [Fig.19.98

(b)]

In this case, the load phase voltages will be no longer equal. The node pair voltage method will be used to solve the question. Let the supply phase voltages be given by

$$\mathbf{E}_R \begin{pmatrix} 231 & 0 \end{pmatrix}, \mathbf{E}_Y \begin{pmatrix} 231 & 120 \end{pmatrix}$$

$$= -115.5 - j200$$

$$\mathbf{E}_B = 231 \angle 120^\circ = -115.5 + j200$$

$$\mathbf{Y}_R \begin{pmatrix} 1/100 & 0.01 \end{pmatrix}; \mathbf{Y}_Y \begin{pmatrix} 1/j10 & j0.1 \end{pmatrix} \text{ and } \mathbf{Y}_B \begin{pmatrix} 1/j10 & j0.1 \end{pmatrix}$$

$$\mathbf{V}_{NN'} = \frac{231 \times 0.01 + (-j0.1)(-115.5 - j200) + j0.1(-115.5 + j200)}{0.01 + (-j0.1) + j0.1} = -3769 + j0$$

The load phase voltages are given by

$$\mathbf{V}_R = \mathbf{E}_R - \mathbf{V}_{NN'} = \begin{pmatrix} 231 & j0 \end{pmatrix} - \begin{pmatrix} 3769 & j0 \end{pmatrix} = 4000 \text{ V}$$

$$\mathbf{V}_Y = \mathbf{E}_Y - \mathbf{V}_{NN'} = \begin{pmatrix} 115.5 & j200 \end{pmatrix} - \begin{pmatrix} 3769 & j0 \end{pmatrix} = \begin{pmatrix} 3653.5 & j200 \end{pmatrix}$$

$$\mathbf{V}_B = \mathbf{E}_B - \mathbf{V}_{NN'} = \begin{pmatrix} 115.5 & j200 \end{pmatrix} - \begin{pmatrix} 3769 & j0 \end{pmatrix} = \begin{pmatrix} 3653.5 & j0 \end{pmatrix}$$

$$\mathbf{I}_R = \mathbf{V}_R \mathbf{Y}_R = 4000 \begin{pmatrix} 0.01 \end{pmatrix} = 40 \text{ A}$$

$$\mathbf{I}_Y = \begin{pmatrix} j0.1 \end{pmatrix} \begin{pmatrix} 3653.5 & j200 \end{pmatrix} = 20 \begin{pmatrix} j3653.5 \end{pmatrix}$$

$$\mathbf{I}_B = \begin{pmatrix} j0.1 \end{pmatrix} \begin{pmatrix} 3653.5 & j200 \end{pmatrix} = 20 \begin{pmatrix} j3653.5 \end{pmatrix}$$

Obviously, the neutral current will just not exist.

**Note.** As hinted in Art. 19.30 (i), the load phase voltages and currents become abnormally high.

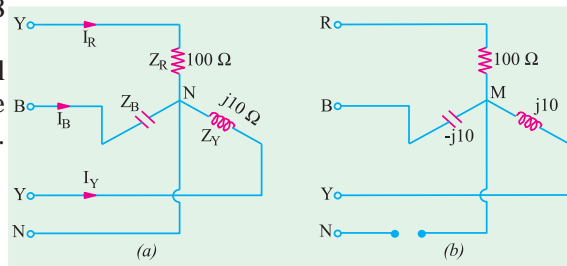

Fig. 19.98

**Example 19.80.** For the circuit shown in Fig. 19.99 find the readings on the two wattmeters  $W_a$  and  $W_c$ .

**Solution.** The three line currents for this problem have already been determined in Example 19.43.

$$I_{ao} = 20.02 - j4.54$$

$$I_{bo} = -7.24 - j5.48$$

$$I_{co} = 12.78 + j10.12$$

The line voltages are given by

$$V_{ab} = 200 \angle 0^\circ$$

$$V_{bc} = -100 - j173.2$$

$$V_{ca} = -100 + j173.2$$

Wattmeter  $W_a$  carries a current of using  $I_{ao} = 20.02 - j4.54$  and has voltage  $V_{ab}$  impressed across its pressure coil. Power can be found by using current conjugate.

$$P_{VA} = (200 + j0)(20.02 + j4.54) = (200)(20.02) + j(200)(4.54)$$

$$\text{Actual power} = 200 \times 20.02 = 4004 \text{ W} \therefore W_a = 4004 \text{ W}$$

The other wattmeter  $W_c$  carries current of  $I_{co} = 12.78 + j10.02$  and has a voltage  $V_{cb} = -V_{bc} = 100 + j173.2$  impressed across it. By the same method, wattmeter reading is

$$W_c = (100 \times -12.78) + (173.2 \times 10.02) = -1278 + 1735.5 = 457.5 \text{ W}$$

**Example 19.81.** Three resistors  $10, 20$  and  $20 \Omega$  are connected in star to the terminals  $A, B$  and  $C$  of a  $3-\phi, 3$  wire supply through two single-phase wattmeters for measurement of total power with current coils in lines  $A$  and  $C$  and pressure coils between  $A$  and  $B$  and  $C$  and  $B$ . Calculate (i) the line currents (ii) the readings of each wattmeter.

The line voltage is  $400\text{-V}$ .

(Electrical Engineering-I, Bombay Univ.)

**Solution.** Let  $V_{AB} = 400 \angle 0^\circ$ ;  $V_{BC} = 400 \angle -120^\circ$  and  $V_{CA} = 400 \angle 120^\circ$

As shown in Fig. 19.100, current through wattmeter  $W_1$  is  $I_{AO}$  or  $I_A$  and that through  $W_2$  is  $I_{CO}$  or  $I_C$  and the voltages are  $V_{AB}$  and  $V_{CB}$  respectively. Obviously,

$$Z_A = 10 \angle 0^\circ; Z_B = 20 \angle 0^\circ; Z_C = 20 \angle 0^\circ$$

The currents  $I_A$  and  $I_C$  may be found by applying either Kirchhoff's laws (Art. 19.33) or Maxwell's Mesh Method. Both methods will be used for illustration.

(a) From Eq. (10), (11) and (12) of Art. 19.33, we have

$$I_A = \frac{400 \times 20 - 20(-200 + j346)}{(10 \times 20) + (20 \times 20) + (20 \times 10)}$$

$$= \frac{12,000 - j6,920}{800} = 15 - j8.65 \text{ A}$$

$$I_C = \frac{20(200 - j346) - 10(200 - j346)}{800} = \frac{2000 - j10,380}{800} = 2.5 - j13$$

(b) From Eq. (i) and (ii) of solved example 17.48 (c) we get

$$I_A = I_1 = \frac{400 \times 40 - 20(200 - j346)}{30 \times 40 + 20^2} = 15 - j8.65 \text{ A}$$

$$I_C = I_2 = \frac{30(200 - j346) - 400 \times 20}{800} = 2.5 - j13$$

As seen, wattmeter  $W_1$  carries current  $I_A$  and has a voltage  $V_{AB}$  impressed across its pressure coil. Power may be found by using voltage conjugate.

$$P_{VA} = (400 \angle 0^\circ)(15 - j8.65) = 6000 - j3,460$$

$$\therefore \text{reading of } W_1 = 6000 \text{ W} = 6 \text{ kW}$$

Similarly,  $W_2$  carries  $I_C$  and has voltage  $V_{CB}$  impressed across its pressure coil.

Now,  $V_{CB} = V_{BC} = 400 \angle -120^\circ$ . Using voltage conjugate, we get

Fig. 19.99

Fig. 19.100

$$P_{VA} = (200 - j346)(2.5 + j13)$$

$$\text{Real power} = (200 \times -2.5) + (13 \times 346) = 4000 \text{ W}$$

$$\therefore \text{reading of } W_2 = \mathbf{4kW}; \quad \text{Total power} = 10 \text{ kW}$$

**Example 19.82.** Three impedances  $Z_A$ ,  $Z_B$  and  $Z_C$  are connected in delta to a 200-V, 3-phase three-wire symmetrical system RYB.

$$Z_A = 10 \angle 60^\circ \text{ between lines R and Y}; \quad Z_B = 10 \angle 0^\circ \text{ between lines Y and B}$$

$$Z_C = 10 \angle 60^\circ \text{ between lines B and R}$$

The total power in the circuit is measured by means of two wattmeters with their current coils in lines R and B and their corresponding pressure coils across R and Y and B and Y respectively. Calculate the reading on each wattmeter and the total power supplied. Phase sequence RYB.

**Solution.** The wattmeter connections are shown in Fig. 19.101.

$$V_{RY} = 200 \angle 0^\circ = 200 + j0$$

$$V_{YB} = 200 \angle 120^\circ = 100 + j173.2$$

$$V_{BR} = 200 \angle 240^\circ = 100 - j173.2$$

$$I_{BR} = \frac{200 \angle 0^\circ}{10 \angle 60^\circ} = 20 \angle -60^\circ = 20 \cos 60^\circ - j20 \sin 60^\circ = 10 - j17.32$$

$$I_{YB} = \frac{200 \angle 120^\circ}{10 \angle 0^\circ} = 20 \angle 120^\circ = 20 \cos 120^\circ + j20 \sin 120^\circ = -10 + j17.32$$

$$= -10 - j17.32; \quad I_{BR} = \frac{200 \angle 120^\circ}{10 \angle 60^\circ} = 20 \angle 60^\circ = 10 + j17.32$$

As seen, current through  $W_1$  is  $I_R$  and voltage across its pressure coil is  $V_{RY}$

$$I_R = I_{RY} = I_{BR} = j34.64 \text{ A}$$

Using voltage conjugate, we have

$$P_{VA} = (200 - j0)(j34.64) = 0 + j6.928$$

Hence,  $W_1$  reads zero.

Current through  $W_2$  is  $I_B$  and voltage across its pressure coil is  $V_{BY}$

$$I_B = I_{BR} = I_{YB} = 20 \angle 34.64^\circ; \quad V_{BY} = V_{YB} = 100 + j173.2$$

Again using voltage conjugate, we get

$$P_{YA} = (100 + j173.2)(20 - j34.64)$$

$$= 8000 + j0$$

$$\therefore \text{reading of } W_2 = \mathbf{8000 \text{ W}}$$

### 19.36. Phase Sequence Indicators

In unbalanced 3-wire star-connected loads, phase voltages change considerably if the phase sequence of the supply is reversed. One or the other load phase voltage becomes dangerously large which may result in damage to the equipment. Some phase voltage becomes too

Fig. 19.101

Fig. 19.102

small which is equally detrimental to some types of electrical equipment. Since phase voltage depends on phase sequence, this fact has been made the basis of several types of phase sequence indicators.\* A simple phase sequence indicator may be made by connecting two suitable incandescent lamps and a capacitor in a  $Y$ -connection as shown in Fig. 19.102. It will be found that for phase sequence  $RYB$ , lamp  $L_1$  will glow because its phase voltage will be large whereas  $L_2$  will not glow because of low voltage across it.

When, phase sequence is  $RBV$ , opposite conditions develop so that this time  $L_2$  glows but not  $L_1$ .

Another method of determining the phase sequence is by means of a small 3-phase motor. Once direction of rotation with a known sequence is found, the motor may be used thereafter for determining an unknown sequence.

### Tutorial Problem No. 19.3

1. Three impedances  $Z_1$ ,  $Z_2$  and  $Z_3$  are mesh-connected to a symmetrical 3-phase, 400-V, 50-Hz supply of phase sequence  $R \rightarrow Y \rightarrow B$ .

$$Z_1 = (10 + j0) \text{ ohm} \text{— between } R \text{ and } Y \text{ lines}$$

$$Z_2 = (5 + j6) \text{ ohm} \quad \text{— between } Y \text{ and } B \text{ lines}$$

$$Z_3 = (5 - j5) \text{ ohm} \quad \text{— between } B \text{ and } R \text{ lines}$$

Calculate the phase and line currents and total power consumed.

$$[40 \text{ A}, 40 \text{ A}, 56.6 \text{ A}; 95.7 \text{ A}, 78.4 \text{ A}, 35.2 \text{ A}; 44.8 \text{ kW}]$$

2. A symmetrical 3- $\phi$ , 380-V supply feeds a mesh-connected load as follows :

Load  $A$  : 19 kVA at p.f. 0.5 lag ; Load  $B$  : 20 kVA at p.f. 0.8 lag ; Load  $C$  : 10 kVA at p.f. 0.9 load  
Determine the line currents and their phase angles for  $RYB$  sequence.

$$[74.6 \angle -51^\circ \text{ A}, 98.6 \angle 172.7^\circ \text{ A}; 68.3 \angle 41.8^\circ \text{ A}]$$

3. Determine the line currents in an unbalanced  $Y$  connected load supplied from a symmetrical 3- $\phi$ , 440-V, 3-wire system. The branch impedances of the load are :  $Z_1 = 5 \angle 30^\circ$  ohm,  $Z_2 = 10 \angle 45^\circ$  ohm and  $Z_3 = 10 \angle 45^\circ$  ohm and  $Z_4 = 10 \angle 60^\circ$  ohm. The sequence is  $RYB$ .

$$[35.7 \text{ A}, 32.8 \text{ A}, 27.7 \text{ A}]$$

4. A 3- $\phi$ ,  $Y$ -connected alternator supplies an unbalanced load consisting of three impedances  $(10 + j20)$ ,  $(10 - j20)$  and  $10 \Omega$  respectively, connected in star. There is no neutral connection. Calculate the voltage between the star point of the alternator and that of the load. The phase voltage of the alternator is 230 V.

$$[-245.2 \text{ V}]$$

5. Non-reactive resistors of 10, 20 and 25  $\Omega$  are star-connected to the  $R$ ,  $Y$  and  $B$  phases of a 400-V, symmetrical system. Determine the current and power in each resistor and the voltage between star point and neutral. Phase sequence,  $RYB$ .

$$[16.5 \text{ A}, 2.72 \text{ kW}; 13.1 \text{ A}, 3.43 \text{ kW}; 11.2 \text{ A}, 3.14 \text{ kW}; 68 \text{ V}]$$

6. Determine the line current in an unbalanced, star-connected load supplied from a symmetrical 3-phase, 440-V system. The branch impedance of the load are  $Z_R = 5 \angle 30^\circ \Omega$ ,  $Z_Y = 10 \angle 45^\circ \Omega$  and  $Z_B = 10 \angle 60^\circ \Omega$ . The phase sequence is  $RYB$ .

$$[35.7 \text{ A}, 32.8 \text{ A}, 27.7 \text{ A}]$$

7. Three non-reactive resistors of 3, 4 and 5- $\Omega$  respectively are star-connected to a 3-phase, 400-V symmetrical system, phase sequence  $RYB$ . Find (a) the current in each resistor (b) the power dissipated in each resistor (c) the phase angles between the currents and the corresponding line voltages (d) the star-point potential. Draw to scale the complete vector diagram.

$$[(a) 66.5 \text{ A}, 59.5 \text{ A}, 51.8 \text{ A} (b) 13.2, 14.15, 13.4 \text{ kW} (c) 26^\circ 24', 38^\circ 10', 25^\circ 20' (d) 34 \text{ V}]$$

8. An unbalanced  $Y$ -connected load is supplied from a 400-V, 3- $\phi$ , 3-wire symmetrical system. The branch circuit impedances and their connection are  $(2 + j2) \Omega$ ,  $R$  to  $N$ ;  $(3 - j3) \Omega$ ,  $Y$  to  $N$  and  $(4 + j1) \Omega$ ,  $B$  to  $N$  of the load. Calculate (i) the value of the voltage between lines  $Y$  and  $N$  and (ii) the phase of this voltage relative to the voltage between line  $R$  and  $Y$ . Phase sequence  $RYB$ .

$$[(i) (-216 - j 135.2) \text{ or } 225.5 \text{ V} (ii) 2^\circ \text{ or } -178^\circ]$$

9. A star-connection of resistors  $R_a = 10 \Omega$ ;  $R_b = 20 \Omega$  is made to the terminals  $A$ ,  $B$  and  $C$  respectively of a symmetrical 400-V,  $\phi$  supply of phase sequence  $A \rightarrow B \rightarrow C$ . Find the branch voltages and currents and star-point voltage to neutral.

\* It may, however, be noted that phase sequence of currents in an unbalanced load is not necessarily the same as the voltage phase sequence. Unless indicated otherwise, voltage phase sequence is implied.

$$[V_A = 148.5 + j28.6 ; I_A = 14.85 + j2.86 ; V_B = -198 - j171.4 ; I_B = -9.9 - j8.57$$

$$V_C = -198 + j228.6 ; I_C = -4.95 + j5.71. V_N = 82.5 - j28.6 \text{ (to be subtracted from supply voltage)}]$$

10. Three non-reactive resistance of 5, 10 and 5 ohm are star-connected across the three lines of a 230-V 3-phase, 3-wire supply. Calculate the line currents.

$$[(18.1 + j21.1) \text{ A} ; (-10.9 - j10.45) \text{ A} ; (-7.3 + j8.4) \text{ A}]$$

11. A 3- $\phi$ , 400-V symmetrical supply feeds a star-connected load consisting of non-reactive resistors of 3, 4 and 5  $\Omega$  connected to the R, Y and B lines respectively. The phase sequence is RYB. Calculate (i) the load star point potential (ii) current in each resistor and power dissipated in each resistor.

$$[(i) 34.5 \text{ V} (ii) 66.4 \text{ A}, 59.7 \text{ A}, 51.8 \text{ A} (iii) 13.22 \text{ kW}, 14.21 \text{ kW}, 13.42 \text{ kW}]$$

12. A 20- $\Omega$  resistor is connected between lines R and Y, a 50- $\Omega$  resistor between lines Y and B and a 10- $\Omega$  resistor between lines B and R of a 415-V, 3-phase supply. Calculate the current in each line and the reading on each of the two wattmeters connected to measure the total power, the respective current coils of which are connected in lines R and Y. [(25.9 - j9); (-24.9 - j7.2); (-1.04 + j16.2); 8.6 kW; 7.75 kW]

13. A three-phase supply, giving sinusoidal voltage of 400 V at 50 Hz is connected to three terminals marked R, Y and B. Between R and Y is connected a resistance of 100  $\Omega$ , between Y and B an inductance of 318 mH and negligible resistance and between B and R a capacitor of 31.8  $\mu\text{F}$ . Determine (i) the current flowing in each line and (ii) the total power supplied. Determine (iii) the resistance of each phase of a balanced star-connected, non-reactive load, which will take the same total power when connected across the same supply. [(i) 7.73 A, 7.73 A, (ii) 1,600 W (iii) 100  $\Omega$  (London Univ.)]

14. An unbalanced, star-connected load is fed from a symmetrical 3-phase system. The phase voltages across two of the arms of the load are  $V_B = 295 \angle 97^\circ 30'$  and  $V_R = 206 \angle -25^\circ$ . Calculate the voltage between the star-point of the load and the supply neutral. [52.2  $\angle -49.54'$ ]

15. A symmetrical 440-V, 3-phase system supplies a star-connected load with the following branch impedances:  $Z_R = 100 \Omega$ ,  $Z_Y = j5 \Omega$ ,  $Z_B = -j5 \Omega$ . Calculate the voltage drop across each branch and the potential of the neutral point to earth. The phase sequence is RYB. Draw the vector diagram.

$$[8800 \angle -30^\circ, 8415 \angle -31.5^\circ, 8420 \angle -28.5^\circ, 8545 \angle 150^\circ]$$

16. Three star-connected impedances,  $Z_1 = (20 + j37.7) \Omega$  per phase are in parallel with three delta-connected impedances,  $Z_2 = (30 - j159.3) \Omega$  per phase. The line voltage is 398 V. Find the line current, power factor, power and reactive volt-amperes taken by the combination.

$$[3.37 \angle 10.4^\circ; 0.984 \text{ lag}; 2295 \text{ W}; 2295 \text{ VAR}; 420 \text{ VAR.}]$$

17. A 3-phase, 440-V, delta-connected system has the loads: branch RY, 20 kW at power factor 1.0; branch YB, 30 kVA at power factor 0.8 lagging; branch BR, 20 kVA at power factor 0.6 leading. Find the line currents and readings on watt-meters whose current coils are in phases R and B.

$$[90.5 \angle 176.5^\circ; 111.4 \angle 14^\circ; 36.7 \angle -119^\circ; 39.8 \text{ kW}; 16.1 \text{ kW}]$$

18. A 415 V, 50 Hz, 3-phase supply of phase sequence RYB is connected to a delta connected load in which branch RY consists of  $R_1 = 100 \Omega$ , branch YB consists of  $R_2 = 20 \Omega$  in series with  $X_2 = 60 \Omega$  and branch BR consists of a capacitor  $C = 30 \mu\text{F}$ . Take  $V_{RY}$  as the reference and calculate the line currents. Draw the complete phasor diagrams. (Elect. Machines, A.M.I.E. Sec. B, 1989)

$$[I_R = 7.78 \angle 14.54^\circ, I_Y = 10.66 \angle 172.92^\circ, I_B = 4.46 \angle -47^\circ]$$

19. Three resistances of 5, 10 and 15  $\Omega$  are connected in delta across a 3-phase supply. Find the values of the three resistors, which if connected in star across the same supply, would take the same line currents.

If this star-connected load is supplied from a 4-wire, 3-phase system with 260 V between lines, calculate the current in the neutral. [2.5  $\Omega$ , 1.67  $\Omega$ , 5  $\Omega$ ; 52 A] (London Univ.)

20. Show that the power consumed by three identical phase loads connected in delta is equal to three times the power consumed when the phase loads are connected in star.

(Nagpur University, Summer 2002)

21. Prove, that the power consumed in balanced three-phase Delta-connected load is three times the power consumed in star-connected load. (Nagpur University, Winter 2002)

22. A three-phase 230 volts system supplies a total load of 2000 watts at a line current of 6 Amp when three identical impedances are in star-connection across the line terminals of the systems. Determine

- the resistive and reactive components of each impedance. *(Nagpur University, Winter 2002)*
- 23.** Three similar coils each of impedance  $z = (8 + j10)$  ohms, are connected in star and supplied from 3-phase 400V, 50 Hz supply. Find the line current, power factor, power and total volt amperes. *(Nagpur University, Summer 2003)*
- 24.** Three similar each having a resistance of 20 ohm and an inductance of 0.05 H are connected in star to a 3-phase 50 Hz supply with 400 V between lines. Calculate power factor, total power absorbed and line current. If the same coil are reconnected in delta across the same supply what will be the power factor, total power absorbed and line current? *(Pune University 2003) (Nagpur University, Winter 2003)*
- 25.** A 3  $\phi$  star connected load when supplied from 440 V, 50 Hz source takes a line current of 12 amp lagging w.r.t. line voltage by  $70^\circ$ . Calculate : (i) impedance parameters (ii) Power factor and its nature (iii) Draw phasor diagram indicating all voltages and currents. *(Nagpur University, Summer 2004)*
- 26.** Derive the relationship between line current and phase current for Delta connected 3 phase load when supplied from 3 phase balanced supply. *(Nagpur University, Summer 2004)*
- 27.** Derive the relationship between line voltage, phase voltage, line current and phase current in a 3 phase star connected and delta connected circuit. *(Gujrat University, June/July 2003)*
- 28.** show that power input to a 3 phase circuit can be measured by two wattmeters connected properly in the circuit. Draw vector diagram. *(Gujrat University, June/July 2003)*
- 29.** A balanced 3 phase star connected load of 100 kW takes a leading current of 100 A when connected across a 3 phase, 1100 V, 50 Hz supply. Calculate the circuit constants of the load per phase. *(Mumbai University 2003) (Gujrat University, June/July 2003)*
- 30.** Establish relationship between line and phase voltages and currents in a balanced 3-phase star connection. Draw complete phasor diagram for voltages and currents. *(R.G.P.V. Bhopal University, June 2004)*
- 31.** A delta connected load has the following impedances :  
 $Z_{RY} = j 10 \Omega$ ,  $Z_{YB} = 10 \angle 0^\circ \Omega$  and  $Z_{BR} = -j 10 \Omega$  If the load is connected across 100 volt balanced 3-phase supply, obtain the line currents. *(R.G.P.V. Bhopal University, June 2004)*
- 32.** Two wattmeters  $\omega_1$  and  $\omega_2$  are used to measure power in a 3 phase balanced circuit. Mention the conditions under which (i)  $\omega_1 = \omega_2$  (ii)  $\omega_2 = 0$  (iii)  $\omega_1 = 2\omega_2$ . *(V.T.U. Belgaum Karnataka University, February 2002)*
- 33.** Three coils each of impedance  $20 \angle 60^\circ \Omega$  are connected across a 400V, 3 phase supply. Find the reading of each of the two wattmeters connected to measure the power when the coils are connected in (i) star (ii) Delta. *(V.T.U. Belgaum Karnataka University, February 2002)*
- 34.** The power input to a 3 phase circuit was measured by two wattmeter method and the readings were 3400 and - 1200 watts respectively. Calculate the total power and powerfactor. *(V.T.U. Belgaum Karnataka University, July/August 2002)*
- 35.** With the help of connection diagram and vector diagram, obtain expressions for the two wattmeter readings used to measure power in a 3 phase the DC generator is running. *(V.T.U. Belgaum Karnataka University, July/August 2002)*
- 36.** Obtain the relationship between line and phase values of current in a three phase, balanced, delta connected system. *(V.T.U. Belgaum Karnataka University, January/February 2003)*
- 37.** Show that in a three phase, balanced circuit, two wattmeters are sufficient to measure the total three phase power and power factor of the circuit. *(V.T.U. Belgaum Karnataka University, January/February 2003)*
- 38.** Each of the two wattmeters connected to measure the input to a three phase circuit, reads 20kW. What does each instrument reads, when the load p.f. is 0.866 lagging with the total three phase power remaining unchanged in the altered condition? *(V.T.U. Belgaum Karnataka University, January/February 2003)*
- 39.** Two wattmeters connected to measure power in a 3 phase circuit read 5KW and 1KW, the latter reading being obtained after reversing current coil connections. Calculate power factor of the load and the total power consumed. *(V.T.U. Belgaum Karnataka University, January/February 2003)*
- 39.** Derive the relationship between phase and line values of voltages in a connected load. *(V.T.U. Belgaum Karnataka University, January/February 2003)*
- 40.** Three coils each of impedance  $20 \angle 60^\circ \Omega$  are connected in delta across a 400, 3 phase, 50Hz, 50Hz Acsupply. Calculate line current and total power. *(V.T.U. Belgaum Karnataka University, January/February 2003)*
- 41.** What are the advantages of a three phase system over a single phase system? *(V.T.U. Belgaum Karnataka University, July/August 2003)*
- 42.** With a neat circuit diagram and a vector diagram prove that two wattmeters are sufficient to measure total power in a 3 phase system. *(V.T.U. Belgaum Karnataka University, July/August 2003)*

- 43.** A balanced star connected load of  $(8 + jb)\Omega$  is connected to a 3 phase, 230 V supply. Find the line current, power factor, power, reactive voltamperes and total voltamperes.  
(V.T.U. Belgaum Karnataka University, July/August 2003)
- 44.** Two watt meters are used to measure the power delivered to a balance 3 phase load of power factor 0.281. One watt meter reads 5.2kW. Determine the reading of the second watt meter. What is the line current if the line voltage is 415 volt?  
(V.T.U. Belgaum Karnataka University, January/February 2004)
- 45.** Write the equations for wattmeter reading  $W_1$  and  $W_2$  in 3 phase power measurement and therefrom for power factor.  
(Anna University, October/November 2002)
- 46.** Show that the wattmeters will read equal in two wattmeter method under unity power factor loading condition.  
(Anna University, November/December 2003)
- 47.** A star connected 3-phase load has a resistance of  $6\Omega$  and an inductive reactance of  $8\Omega$  in each branch. Line voltage is 220 volts. Write the phasor expressions for voltage across each branch, line voltages and line currents. Calculate the total power.  
(Anna University, November/December 2003)
- 48.** Two wattmeters connected to measure the total power in a 3-phase balanced circuit. One measures 4,800 W, while the other reads backwards. On reversing the latter it is found to read 400 W. What is the total power and power and power factor? Draw the connection diagram and phasor diagram of the circuit.  
(Mumbai University 2003) (RGPV Bhopal 2001)
- 49.** A star-network in which N is star point made up as follows :  
AN =  $70\Omega$ , CN =  $90\Omega$  Find an equivalent delta network. If the above star-delta network are superimposed, what would be measured resistance between A and C?  
(Pune University, 2003) (RGPV Bhopal 2001)
- 50.** Explain with diagram the measurement of 3-phase power by two-wattmeter method.  
(RGPV Bhopal 2002)
- 51.** Show that the power taken by a 3-phase circuit can be measured by two wattmeters connected properly in the circuit.  
(RGPV Bhopal)
- 52.** With the aid of star-delta connection diagram, state the basic equation from which star-delta conversion equation can be derived.  
(Pune University, 2003) (RGPV Bhopal 2001)
- 53.** Star-delta connections in a 3-phase supply and their inter-relationship. (RGPV Bhopal 2001)

- 56.** Differentiate between balanced and unbalanced three-phase supply and balanced and unbalanced three-phase load. (RGPV Bhopal June 2002)
- 57.** A 3-phase 3 wire supply feeds a load consisting of three equal resistors. By how much is the load reduced if one of the resistors be removed ?  
(RGPV Bhopal June 2002)
- 58.** Establish relationship between line and phase voltages and currents in a balanced delta connection. Draw complete phasor diagram of voltages and currents. (RGPV Bhopal December 2003)

### OBJECTIVE TESTS – 19

- The minimum number of wattmeter (s) required to measure 3-phase, 3-wire balanced or unbalanced power is  
(a) 1  
(b) 2  
(c) 3  
(d) 4  
(GATE 2001)
- A wattmeter reads 400 W when its current coil is connected in the R phase and its pressure coil is connected between this phase and the neutral of a symmetrical 3-phase system supplying a balanced star connected 0.8 p.f. inductive load. The phase sequence is RYB. What will be the reading of this wattmeter if its pressure coil alone is reconnected between the B and Y phases, all other connections remaining as before?  
(a) 33  $\frac{1}{3}$   
(b) 50  
(c) 66  $\frac{2}{3}$   
(d) 75 (GATE)
- Total instantaneous power supplied by a 3-phase ac supply to a balanced R-L load is  
(a) zero  
(b) constant  
(c) pulsating with zero average  
(d) pulsating with non-zero average  
(GATE 2004)
- A balanced 3-phase, 3-wire supply feeds balanced star connected resistors. If one of the resistors is disconnected, then the percentage reduction in the load will be  
(a) 33  $\frac{1}{3}$   
(b) 50  
(c) 66  $\frac{2}{3}$   
(d) 75 (GATE)

# CHAPTER 20

## Learning Objectives

- Fundamental Wave and Harmonics
- Different Complex Waveforms
- General Equation of a Complex Wave
- R.M.S. Value of a Complex Wave
- Form Factor of a Complex Wave
- Power Supplied by a Complex Wave
- Harmonics in Single-phase A.C. Circuits
- Selective Resonance Due to Harmonics
- Effect of Harmonics on Measurement of Inductance and Capacitance
- Harmonics in Different Three-phase Systems
- Harmonics in Single and 3-Phase Transformers

## HARMONICS

Harmonics are the multiples of a sine wave (the fundamental frequency)

## 20.1. Fundamental Wave and Harmonics

Upto this stage, while dealing with alternating voltages and currents, it has been assumed that they have sinusoidal waveform or shape. Such a waveform is an ideal one and much sought after by the manufacturers and designers of alternators. But it is nearly impossible to realize such a waveform in practice. All the alternating waveforms deviate, to a greater or lesser degree, from this ideal sinusoidal shape. Such waveforms are referred to as **non-sinusoidal** or **distorted** or **complex waveforms**.

Fig. 20.1

Fig. 20.2

Complex waveforms are produced due to the superposition of sinusoidal waves of different frequencies. Such waves occur in speech, music, TV, rectifier outputs and many other applications of electronics. On analysis, it is found that a complex wave essentially consists of

(a) a **fundamental** wave – it has the lowest frequency, say ' $f$ '

(b) a number of other sinusoidal waves whose frequencies are an integral multiple of the fundamental or basic frequency like  $2f$ ,  $3f$  and  $4f$  etc.

The fundamental and its higher multiples form a **harmonic** series.

As shown in Fig. 20.1, fundamental wave itself is called the **first** harmonic. The **second** harmonic has frequency **twice** that of the fundamental, the **third** harmonic has frequency **thrice** that of the fundamental and so on.

Waves having frequencies of  $2f$ ,  $4f$  and  $6f$  etc. are called **even harmonics** and those having frequencies of  $3f$ ,  $5f$  and  $7f$  etc. are called **odd harmonics**. Expressing the above in angular frequencies, we may say that successive odd harmonics have frequencies of  $3\omega$ ,  $5\omega$  and  $7\omega$  etc. and even harmonics have frequencies of  $2\omega$ ,  $4\omega$  and  $6\omega$  etc.

As mentioned earlier, harmonics are introduced in the output voltage of an alternator due to many reasons such as the irregularities of the flux distribution in it. Considerations of waveform and form factor are very important in the transmission of a.c. power but they are of much greater importance in radio work where the intelligibility of a signal is critically dependent on the faithful transmission of the harmonic structure of sound waves. In fact, it is only the rich harmonic content of the consonants and lesser at still plentiful harmonic content of vowels which helps the ear to distinguish a well regulated speech from a more rhythmical succession of musical sounds.

### 20.2. Different Complex Waveforms

Let us now find out graphically what the resultant shape of a complex wave is when we combine the fundamental with one of its harmonics. Two cases would be considered (i) when the fundamental and harmonic are in phase with each other and have equal or unequal amplitudes and (ii) when there is some phase difference between the two.

In Fig. 20.2 (a), the fundamental and second harmonic, both having the same amplitude, have been shown by the firm and broken line respectively. The resultant complex waveform is plotted out by algebraically adding the individual ordinates and is shown by thick line.

It may be noted that since the maximum amplitude of the harmonic is equal to the maximum amplitude of the fundamental, the complex wave is said to contain 100% of second harmonic.

Fig. 20.3

Fig. 20.4

The complex wave of Fig. 20.2 (b) is made up of the fundamental and 4th harmonic, that of Fig. 20.2 (c) consists of the fundamental and 3rd harmonic whereas that shown in Fig. 20.2 (d) is made up of the fundamental and 5th harmonic. Obviously, in all these cases, there is no phase difference between the fundamental and the harmonic.

Fig. 20.2 (a) and (c) have been reconstructed as Fig. 20.3 (a) and (b) respectively with the only difference that in this case, the amplitude of harmonic is half that of the fundamental *i.e.* the harmonic content is 50%.

The effect of phase difference between the fundamental and the harmonic on the shape of the resultant complex wave has been illustrated in Fig. 20.4.

Fig. 20.4 (a) shows the fundamental and second harmonic with phase difference of  $\pi/2$  and Fig. 20.4 (b) shows the same with a phase difference of  $\pi$ . In Fig. 20.4 (c) and (d) are shown the fundamental and third harmonic with a phase difference of  $\pi/2$  and  $\pi$  respectively. In all these figures, the amplitude of the harmonic has been taken equal to half that of the fundamental.

A careful examination of the above figures leads us to the following conclusions :

**1.** With **odd** harmonics, the positive and negative halves of the complex wave are symmetrical whatever the phase difference between the fundamental and the harmonic. In other words, the first and third quarters (*i.e.*  $\omega t$  from 0 to  $\pi/2$  and  $\omega t$  from  $3\pi/2$ ) and the second and fourth quarters (*i.e.*  $\omega t$  from  $\pi/2$  to  $\pi$  and  $\omega t$  from  $3\pi/2$  to  $2\pi$ ) are respectively similar.

**2. (i)** When **even** harmonics are present and their phase difference with the fundamental is 0 or  $\pi$ , then the first and fourth quarters of the complex wave are of the same phase but inverted and the same holds good for the second and third quarters.

**(ii)** When **even** harmonics are present and their phase difference with the fundamental is  $\pi/2$  or  $3\pi/2$ , then there is no symmetry as shown in Fig. 20 (a).

**3.** It may also be noted that the resultant displacement of the complex wave (whether containing odd or even harmonics) is zero at  $\omega t = 0$  only when the phase difference between the fundamental and the harmonics is either 0 to  $\pi$ .

The above conclusions are of great help in analysing a complex waveform into its harmonic constituents because a visual inspection of the complex wave enables us to rule out the presence of certain harmonics. For example, if the positive and negative half-cycles of a complex wave are symmetrical (*i.e.* the wave is symmetrical about  $\omega t = 0$ ), then we need not look for even harmonics. In some cases, we may be able to forecast the types of harmonics to be expected from their mode of production. For example, in alternators which are symmetrically designed, we should expect **odd** harmonics only.

### 20.3. General Equation of a Complex Wave

Consider a complex wave which is built up of the fundamental and a few harmonics, each of which has its own peak value of phase angle. The fundamental may be represented by

$$e_1 = E_{1m} \sin(\omega t + \Psi_1)$$

the second harmonic by  $e_2 = E_{2m} \sin(2\omega t + \Psi_2)$

the third harmonic by  $e_3 = E_{3m} \sin(3\omega t + \Psi_3)$  and so on.

The equation for the instantaneous value of the complex wave is given by

$$e = e_1 + e_2 + \dots + e_n = E_{1m} \sin(\omega t + \Psi_1) + E_{2m} \sin(2\omega t + \Psi_2) + \dots + E_{nm} \sin(n\omega t + \Psi_n)$$

when  $E_{1m}$ ,  $E_{2m}$  and  $E_{nm}$  etc. denote the maximum values or the amplitudes of the fundamental, second harmonic and  $n$ th harmonic etc. and  $\Psi_1$ ,  $\Psi_2$  and  $\Psi_n$  represent the phase differences with

respect to the complex wave\* (i.e. angle between the zero value of complex wave and the corresponding zero value of the harmonic).

The number of terms in the series depends on the shape of the complex wave. In relatively simple waves, the number of terms in the series would be less, in others, more.

Similarly, the instantaneous value of the complex wave is given by

$$i = I_{1m} \sin(\omega t + \phi_1) + I_{2m} \sin(2\omega t + \phi_2) + \dots + I_{nm} \sin(n\omega t + \phi_n)$$

Obviously  $(\Psi_1 - \phi_1)$  is the phase difference between the harmonic voltage and current for the fundamental,  $(\Psi_2 - \phi_2)$  for the second harmonic and  $(\Psi_n - \phi_n)$  for the  $n$ th harmonic.

## 20.4. R.M.S. Value of a Complex Wave

Let the equation of the given complex current wave be

$$i = I_{1m} \sin(\omega t + \phi_1) + I_{2m} \sin(2\omega t + \phi_2) + \dots + I_{nm} \sin(n\omega t + \phi_n)$$

Its r.m.s. value is given by  $I = \sqrt{\text{average value of } i^2 \text{ over whole cycle}}$

$$\begin{aligned} \text{Now } i^2 &= [I_{1m} \sin(\omega t + \phi_1) + I_{2m} \sin(2\omega t + \phi_2) + \dots + I_{nm} \sin(n\omega t + \phi_n)]^2 \\ &= I_{1m}^2 \sin^2(\omega t + \phi_1) + I_{2m}^2 \sin^2(2\omega t + \phi_2) + \dots + I_{nm}^2 \sin^2(n\omega t + \phi_n) \\ &\quad + 2I_{1m}I_{2m} \sin(\omega t + \phi_1) \sin(2\omega t + \phi_2) + 2I_{1m}I_{3m} \sin(\omega t + \phi_1) \sin(3\omega t + \phi_3) + \dots \end{aligned}$$

The right-hand side of the above equation consists of two types of terms

- (i) harmonic self-products, the general expression for which is  $I_{pm}^2 \sin^2(p\omega t + \phi_p)$  for the  $p$ th harmonic and
- (ii) the products of different harmonics of the general form  $2I_{pm}I_{qm} \sin(p\omega t + \phi_p) \sin(q\omega t + \phi_q)$

The average value of  $i^2$  is the sum of the average values of these individual terms in the above equation. Let us now find the average value of the general term  $I_{pm}^2 \sin^2(p\omega t + \phi_p)$  over a whole cycle.

$$\begin{aligned} \text{Average value} &= \frac{1}{2\pi} \int_0^{2\pi} I_{pm}^2 \sin^2(p\omega t + \phi_p) d(\omega t) = \frac{I_{pm}^2}{2} \int_0^{2\pi} \sin^2(p\omega t + \phi_p) d\omega t \\ &= \frac{I_{pm}^2}{2} \int_0^{2\pi} \frac{1 - \cos 2(p\omega t + \phi_p)}{2} d\omega t = \frac{I_{pm}^2}{4} \left[ \omega t - \frac{\sin 2(p\omega t + \phi_p)}{2p} \right]_0^{2\pi} \\ &= \frac{I_{pm}^2}{4\pi} \times 2\pi = \frac{I_{pm}^2}{2} \end{aligned}$$

From this result, we can generalize that

$$\text{Average value of } I_{1m}^2 \sin^2(\omega t + \phi_1) = \frac{I_{1m}^2}{2}$$

$$\text{Average value of } I_{2m}^2 \sin^2(2\omega t + \phi_2) = \frac{I_{2m}^2}{2}$$

\* We could also express these phase angles with respect to the fundamentals wave instead of the complex wave.

Average value of  $I_{nm}^2 \sin^2(n\omega t + \phi_n) = \frac{I_{nm}^2}{2}$  and so on.

Now, the average value of the product terms is

$$\frac{1}{2} \int_0^{2\pi} I_{pm} I_{qm} \sin(p t + \phi_p) \sin(q t + \phi_q) d(t)$$

$$\frac{I_{pm} I_{qm}}{2} \int_0^{2\pi} \sin(p t + \phi_p) \sin(q t + \phi_q) d t = 0$$

$\therefore$  Average value of  $i^2 = \frac{I_{1m}^2}{2} + \frac{I_{2m}^2}{2} + \dots + \frac{I_{nm}^2}{2}$

$$\therefore \text{r.m.s. value, } I = \sqrt{\text{average value of } i^2} = \sqrt{\frac{I_{1m}^2}{2} + \frac{I_{2m}^2}{2} + \dots + \frac{I_{nm}^2}{2}}$$

... (i)

$$= 0.707 \sqrt{I_{1m}^2 + I_{2m}^2 + \dots + I_{nm}^2}$$

Equation (i) above may also be put in the form

$$I = \sqrt{\frac{I_{1m}^2}{\sqrt{2}^2} + \frac{I_{2m}^2}{\sqrt{2}^2} + \dots + \frac{I_{nm}^2}{\sqrt{2}^2}} = \sqrt{I_1^2 + I_2^2 + \dots + I_n^2}$$

where  $I_1 = I_{1m} / \sqrt{2}$  – r.m.s. value of fundamental

$I_2 = I_{2m} / \sqrt{2}$  – r.m.s. value of 2nd harmonic

$I_n = I_{nm} / \sqrt{2}$  – r.m.s. value of  $n$ th harmonic

Similarly, the r.m.s. value of a complex voltage wave is

$$E = 0.707 \sqrt{E_{1m}^2 + E_{2m}^2 + \dots + E_{nm}^2} = \sqrt{E_1^2 + E_2^2 + \dots + E_n^2}$$

Hence, the **rule is that the r.m.s. value of the complex current (or voltage) wave is given by the square-root of the sum of the squares of the r.m.s. values of its individual components.**

**Note.** If complex current wave contains a d.c. component of constant value  $I_D$  then its equation is given by

$$i = I_D + I_{1m} \sin(\omega t + \phi_1) + I_{2m} \sin(2\omega t + \phi_2) + \dots + I_{nm} \sin(n\omega t + \phi_n)$$

$$\text{r.m.s. value, } I = \sqrt{I_D^2 + (I_{1m}/\sqrt{2})^2 + (I_{2m}/\sqrt{2})^2 + \dots + (I_{nm}/\sqrt{2})^2} = \sqrt{I_D^2 + I_1^2 + I_2^2 + \dots + I_n^2}$$

## 20.5. Form Factor of a Complex Wave

In general, it may be defined as  $k_f = \frac{\text{R.M.S. value}}{\text{average value}}$

A general expression for form factor in some simple cases may be found as under :

(i) **Sine Series.** Suppose the equation of a complex voltage wave is

$$v = V_{1m} \sin \omega t \pm V_{3m} \sin 3\omega t \pm V_{5m} \sin 5\omega t$$

$$= V_{1m} \sin \theta \pm V_{3m} \sin 3\theta \pm V_{5m} \sin 5\theta \quad \text{where } \omega = 2\pi / T.$$

Obviously, zeros occurs at  $t = 0$  or at  $\theta = 0^\circ$  and  $\theta = 180^\circ$  or  $t = T/2$ .

Mean value over half-cycle is

$$V_{av} = \frac{1}{\pi} \int_0^\pi v d\theta$$

$$\frac{1}{\sqrt{2}} \left( V_{1m} \sin \omega t + V_{3m} \sin 3\omega t + V_{5m} \sin 5\omega t \right) = \frac{2}{\sqrt{2}} \left( \frac{V_{1m}}{1} + \frac{V_{3m}}{3} + \frac{V_{5m}}{5} \right)$$

As found in Art. 20.4,

$$V = (V_1^2 + V_3^2 + V_5^2)^{1/2} = \frac{1}{\sqrt{2}} (V_{1m}^2 + V_{3m}^2 + V_{5m}^2)^{1/2}$$

$$\therefore k_f = \frac{(1/\sqrt{2})(V_{1m}^2 + V_{3m}^2 + V_{5m}^2)^{1/2}}{\frac{2}{\sqrt{2}} \left( \frac{V_{1m}}{1} + \frac{V_{3m}}{3} + \frac{V_{5m}}{5} \right)}$$

(ii) **Cosine Series.** Consider the following cosine series :

$$v = V_{1m} \cos \omega t + V_{3m} \cos 3\omega t + V_{5m} \cos 5\omega t$$

$$= V_{1m} \cos \theta + V_{3m} \cos 3\theta + V_{5m} \cos 5\theta$$

Obviously, in this case, zeros occur at  $\theta = \pm\pi/2$  or  $90^\circ$ . Moreover, positive and negative half-cycles are symmetrical.

$$\therefore V_{av} = \frac{1}{2} (V_{1m} \cos \theta + V_{3m} \cos 3\theta + V_{5m} \cos 5\theta) = \frac{2}{\sqrt{2}} \left( \frac{V_{1m}}{1} + \frac{V_{3m}}{3} + \frac{V_{5m}}{5} \right)$$

$$\therefore k_f = \frac{(1/\sqrt{2})(V_{1m}^2 + V_{3m}^2 + V_{5m}^2)^{1/2}}{\frac{2}{\sqrt{2}} \left( \frac{V_{1m}}{1} + \frac{V_{3m}}{3} + \frac{V_{5m}}{5} \right)}$$

**Example 20.1.** A voltage given by  $v = 50 + 24 \sin \omega t - 20 \sin 2\omega t$  is applied across the circuit shown in Fig. 20.5. What would be the readings of the instruments if  $\omega = 10,000$  rad/s.  $A_1$  is thermoelectric ammeter,  $A_2$  a moving-coil ammeter and  $V$  an electrostatic voltmeter.

**Solution.** It may be noted that the thermoelectric ammeter and the electrostatic voltmeter record the r.m.s. values of the current and voltage respectively. But the moving coil ammeter records the average values. Since the average values of the sinusoidal waves are zero, hence the moving coil ammeter reads the d.c. component of the current only. The d.c. will pass only through the inductive branch and not through the capacitive branch.

Fig. 20.5

$$\therefore I_{DC} = \frac{V_{DC}}{R} = \frac{50}{250} = 0.2 \text{ A}$$

Equivalent impedance of the circuit at fundamental frequency is

$$Z_1 = \frac{(R - jX_{L1})(jX_{C1})}{R - jX_{L1} + jX_{C1}} = \frac{(250 - j50)(j50)}{250 - j(50 - 50)} = \frac{2,500 + j12,500}{250} = 10 + j50 = 51 \angle 78^\circ 42'$$

$$\therefore \text{r.m.s. fundamental current } I_1 = I_{1m} / \sqrt{2} = 24 / 51 \times \sqrt{2} = 0.33 \text{ A}$$

Equivalent impedance of the circuit at the second harmonic is

$$Z_2 = \frac{(R - jX_{L2})(jX_{C2})}{R - jX_{L2} + jX_{C2}} = \frac{(250 - j100)(j25)}{200 - j75} = 31.5 \angle 88^\circ 43'$$

$\therefore$  r.m.s. value of second harmonic current

$$I_2 = I_{2m} / \sqrt{2} = 20 / 31.5 \times \sqrt{2} = 0.449 \text{ A}$$

r.m.s. current in the circuit is

$$I = \sqrt{I_{DC}^2 + I_1^2 + I_2^2} = \sqrt{0.2^2 + 0.33^2 + 0.449^2} = 0.593 \text{ A}$$

Hence, the reading of the thermoelectric ammeter is **0.593 A**

$$\text{The voltmeter reading } V = \sqrt{50^2 + (24/\sqrt{2})^2 + (20/\sqrt{2})^2} = \mathbf{54.66}$$

**Example 20.2.** Draw one complete cycle of the following wave

$$i = 100 \sin \omega t + 40 \sin 5 \omega t$$

Determine the average value, the r.m.s. value and form factor of the wave.

(Elect. Engineering, Osmania Univ.)

$$\text{Solution. } I_{av} = \frac{2}{1} \frac{I_{2m}}{5} = \frac{2}{1} \frac{100}{5} = \mathbf{68.7 \text{ A}}$$

$$I = \sqrt{\frac{I_{1m}^2}{2} + \frac{I_{5m}^2}{2}} = \frac{1}{\sqrt{2}} (100^2 + 40^2)^{1/2} = \mathbf{76.2 \text{ A}}$$

$$\text{Form factor} = \frac{I}{I_{av}} = \frac{76.2}{68.7} = \mathbf{1.109}$$

## 20.6. Power Supplied by a Complex Wave

Let the complex voltage be represented by the equation

$$e = E_{1m} \sin \omega t + E_{2m} \sin 2\omega t + \dots + E_{nm} \sin n\omega t$$

be applied to a circuit. Let the equation of the resultant current wave be

$$i = I_{1m} \sin(\omega t + \phi_1) + I_{2m} \sin(2\omega t + \phi_2) + \dots + I_{nm} \sin(n\omega t + \phi_n)$$

The instantaneous value of the power in the circuit is  $p = ei$  watt

For obtaining the value of this product, we will have to multiply every term of the voltage wave, in turn, by every term in the current wave. The average power supplied during a cycle would be equal to the sum of the average values over one cycle of each individual product term. However, as proved in Art. 20.4 earlier, the average value of all product terms involving harmonics of different frequencies will be zero over one cycle, so that we need consider only the products of current and voltage harmonics of the same frequency.

Let us consider a general term of this nature *i.e.*  $E_{nm} \sin n\omega t \times I_{nm} \sin(n\omega t - \phi_n)$  and find its average value over one cycle of the fundamental.

$$\text{Average value of power} = \frac{1}{2} \int_0^{2\pi} E_{nm} I_{nm} \sin n t \sin(n t - \phi_n) d(t)$$

$$= \frac{E_{nm} I_{nm}}{2} \int_0^{2\pi} \sin n t \sin(n t - \phi_n) d(t)$$

$$= \frac{E_{nm} I_{nm}}{2} \int_0^{2\pi} \frac{\cos \phi_n - \cos(2n t - \phi_n)}{2} d(t)$$

$$= \frac{E_{nm} I_{nm} \cos \phi_n}{2} = \frac{E_{nm}}{\sqrt{2}} \cdot \frac{I_{nm}}{\sqrt{2}} \cdot \cos \phi_n = E_n I_n \cos \phi_n$$

where  $E_n$  and  $I_n$  are the r.m.s. values of the voltage and current respectively. Hence, total average power supplied by a complex wave is **the sum of the average power supplied by each harmonic component acting independently.**

$$\therefore \text{Total power is } P = E_1 I_1 \cos \phi_1 + E_2 I_2 \cos \phi_2 + \dots + E_n I_n \cos \phi_n$$

The overall power factor is given by

$$\text{pf.*} = \frac{\text{total watts}}{\text{total voltamperes}} = \frac{E_1 I_1 \cos \phi_1 + E_2 I_2 \cos \phi_2 + \dots}{E I}$$

when

$E$  = r.m.s. value of the complex voltage wave

$I$  = r.m.s. value of the complex current wave

**Example 20.3.** A single-phase voltage source 'e' is given by

$$e = 141 \sin \omega t + 42.3 \sin 3\omega t + 28.8 \sin 5\omega t$$

The corresponding current in the load circuit is given by

$$i = 16.5 \sin(\omega t + 54.5^\circ) + 8.43 \sin(3\omega t - 38^\circ) + 4.65 \sin(5\omega t - 34.3^\circ)$$

Find the power supplied by the source.

(Electrical Circuits, Nagpur Univ. 1991)

**Solution.** In problems of such type, it is best to deal with each harmonic separately  
Power at fundamental

$$= E_1 I_1 \cos \phi_1 = \frac{E_{1m}}{\sqrt{2}} \cdot \frac{I_{1m}}{\sqrt{2}} \cos \phi_1 = \frac{E_{1m} I_{1m}}{2} \cos \phi_1 = \frac{141 \times 16.5}{2} \cos 54.5^\circ = 675.5 \text{ W}$$

$$\text{Power at 3rd harmonic} = \frac{E_{3m} I_{3m}}{2} \cos \phi_3 = \frac{42.3 \times 8.43}{2} \cos 38^\circ = 140.5 \text{ W}$$

$$\text{Power at 5th harmonic} = \frac{28.8 \times 4.65}{2} \cos 34.3^\circ = 55.5 \text{ W}$$

$$\text{Total power supplied} = 675.5 + 140.5 + 55.5 = \mathbf{871.5 \text{ W}}$$

**Example 20.4.** A complex voltage is given by  $e = 60 \sin \omega t + 24 \sin(3\omega t + \omega/6) + 12 \sin(5\omega t + \pi/3)$  is applied across a certain circuit and the resulting current is given by

$$i = 0.6 \sin(\omega t - 2\pi/10) + 0.12 \sin(\omega t - 2\pi/24) + 0.1 \sin(5\pi - 3\pi/4)$$

Find (i) r.m.s value of current and voltage (ii) total power supplied and (iii) the overall power factor.

**Solution.** In such problems where harmonics are involved, it is best to deal with each harmonic separately.

$$\text{Power at fundamental} = E_1 I_1 \cos \phi_1 = \frac{E_{1m} I_{1m}}{2} \cos \phi_1 = \frac{60 \times 0.6}{2} \times \cos 36^\circ = 14.56 \text{ W}$$

$$\text{Power at 3rd harmonic} = \frac{E_{3m} I_{3m}}{2} \cos 45^\circ = \frac{24 \times 0.12}{2} \times 0.707 = 1.02 \text{ W}$$

$$\text{Power at 5th harmonic} = \frac{E_{5m} I_{5m}}{2} \cos 75^\circ = \frac{12 \times 0.1}{2} \times 0.2588 = 0.16 \text{ W}$$

\* When harmonics are present, it is obvious that the overall p.f. of the circuit cannot be stated lagging or leading. It is simply the ratio of power in watts of voltamperes.

$$(i) \text{ R.M.S. current } I = \sqrt{I_1^2 + I_3^2 + I_5^2} = \sqrt{\frac{I_{1m}^2}{2} + \frac{I_{3m}^2}{2} + \frac{I_{5m}^2}{2}}$$

$$= \sqrt{\frac{0.6^2}{2} + \frac{0.12^2}{2} + \frac{0.1^2}{2}} = 0.438 \text{ A}$$

$$\text{R.M.S. volts, } E = \sqrt{\frac{60^2}{2} + \frac{24^2}{2} + \frac{12^2}{2}} = 46.5 \text{ V}$$

$$(ii) \text{ Total power} = 14.56 + 1.02 + 0.16 = 15.74 \text{ W}$$

$$(iii) \text{ Overall p.f.} = \frac{\text{watts}}{\text{voltamperes}} = \frac{15.74}{46.5 \times 0.438} = 0.773$$

## 20.7. Harmonics in Single-phase A.C. Circuits

If an alternating voltage, containing various harmonics, is applied to a single-phase circuit containing linear circuit elements, then the current so produced also contains harmonics. Each harmonic voltage will produce its own current independent of others. By the principle of superposition, the combined current can be found. We will now consider some of the well-known elements like pure resistance, pure inductance and pure capacitance and then various combinations of these. In each case, we will assume that the applied complex voltage is represented by

$$e = E_{1m} \sin \omega t + E_{2m} \sin 2\omega t + \dots + E_{nm} \sin n\omega t$$

### (a) Pure Resistance

Let the circuit have a resistance of  $R$  which is independent of frequency.

The instantaneous current  $i_1$  due to fundamental voltage is

$$i_1 = \frac{E_{1m} \sin \omega t}{R}$$

Similarly,  $i_2 = \frac{E_{2m} \sin 2\omega t}{R}$  for 2nd harmonic

and  $i_n = \frac{E_{nm} \sin n t}{R}$  ... for  $n$ th harmonic

total current  $i = i_1 + i_2 + \dots + i_n$

$$= \frac{E_{1m} \sin \omega t}{R} + \frac{E_{2m} \sin 2\omega t}{R} + \dots + \frac{E_{nm} \sin n\omega t}{R}$$

$$= I_{1m} \sin \omega t + I_{2m} \sin 2\omega t + \dots + I_{nm} \sin n\omega t$$

It shows that

- (i) the waveform of the resulting current is similar to that of the applied voltage *i.e.* the two waves are identical.
- (ii) the percentage of harmonic content in the current wave is the same as in the applied voltage.

### (b) Pure Inductance

Let the inductance of the circuit be  $L$  henry whose reactance varies directly as the frequency of the applied voltage. Its reactance for the fundamental would be  $X_1 = \omega L$ ; for the second harmonic,  $X_2 = 2\omega L$ , for the third harmonic,  $X_3 = 3\omega L$  and for the  $n$ th harmonic  $X_n = n\omega L$ .

However, for every harmonic term, the current will lag behind the voltage by  $90^\circ$ .

$$\text{Current due to fundamental, } i_1 = \frac{E_{1m}}{\omega L} \sin(\omega t - \pi/2)$$

$$\text{Current due to 2nd harmonic, } i_2 = \frac{E_{2m}}{2\omega L} \sin(2\omega t - \pi/2)$$

$$\text{Current due to 3rd harmonic, } i_3 = \frac{E_{3m}}{3\omega L} \sin(3\omega t - \pi/2)$$

$$\text{Current due to } n\text{th harmonic, } i_n = \frac{E_{nm}}{n\omega L} \sin(n\omega t - \pi/2)$$

$\therefore$  Total current  $i = i_1 + i_2 + \dots + i_n$

$$\frac{E_{1m}}{L} \sin(\omega t - \pi/2) + \frac{E_{2m}}{2L} \sin(2\omega t - \pi/2) + \dots + \frac{E_{nm}}{nL} \sin(n\omega t - \pi/2)$$

It can be seen from the above equation that

- (i) the waveform of the current differs from that of the applied voltage.
- (ii) for the  $n$ th harmonic, the percentage harmonic content in the current-wave is  $1/n$  of the corresponding harmonic content in the voltage wave. It means that in an inductive circuit, the current waveform shows less distortion than the voltage waveform. In this case, current more nearly approaches a sine wave than it does in a circuit containing resistance.

### (c) Pure Capacitance

In this case,

$$X_1 = \frac{1}{\omega C} \text{ - for fundamental ; } X_2 = \frac{1}{2\omega C} \text{ - for 2nd harmonic}$$

$$X_3 = \frac{1}{3\omega C} \text{ - for 3rd harmonic ; } X_n = \frac{1}{n\omega C} \text{ - for } n\text{th harmonic}$$

$$i_1 = \frac{E_{1m}}{1/\omega C} \sin(\omega t + \pi/2) = \omega C E_{1m} \sin(\omega t + \pi/2)$$

$$i_2 = \frac{E_{2m}}{1/2\omega C} \sin(2\omega t + \pi/2) = 2\omega C E_{2m} \sin(2\omega t + \pi/2)$$

$$i_n = \frac{E_{nm}}{1/n\omega C} \sin(n\omega t + \pi/2) = n\omega C E_{nm} \sin(n\omega t + \pi/2)$$

For every harmonic term, the current will lead the voltage by  $90^\circ$ .

Now  $i = i_1 + i_2 + \dots + i_n$

$$= \omega C E_{1m} \sin(\omega t + \pi/2) + 2\omega C E_{2m} \sin(2\omega t + \pi/2) + \dots + n\omega C E_{nm} \sin(n\omega t + \pi/2)$$

This equation shows that

- (i) the current and voltage waveforms are dissimilar.
- (ii) percentage harmonic content of the current is larger than that of the applied voltage wave. For example, for  $n$ th harmonic, it would be  $n$  time larger.
- (iii) as a result, the current wave is more distorted than the voltage wave.
- (iv) effect of capacitor on distortion is just the reverse of that of inductance.

**Example 20.5.** A complex wave of r.m.s. value 240 V has 20% 3rd harmonic content, 5% 5th harmonic content and 2% 7th harmonic content. Find the r.m.s. value of the fundamental and of each harmonic. **(Elect. Circuits, Gujarat Univ.)**

**Solution.** Let  $V_1$ ,  $V_3$ ,  $V_5$  and  $V_7$  be the r.m.s. values of the fundamental and harmonic voltages. Then

$$V_3 = 0.2 V_1; \quad V_5 = 0.05 V_1 \text{ and } V_7 = 0.02 V_1$$

$$240 = (V_1^2 + V_3^2 + V_5^2 + V_7^2)^{1/2}$$

$$\therefore 240 = [V_1^2 + (0.2 V_1)^2 + (0.05 V_1)^2 + (0.02 V_1)^2]^{1/2}$$

$$\therefore V_1 = \mathbf{235 \text{ V}}; \quad V_3 = 0.2 \times 235 = \mathbf{47 \text{ V}}$$

$$V_5 = 0.05 \times 235 = \mathbf{11.75 \text{ V}}; \quad V_7 = 0.02 \times 235 = \mathbf{4.7 \text{ V}}$$

**Example 20.6.** Derive an expression for the power, power factor and r.m.s. value for a complex wave.

A voltage  $e = 250 \sin \omega t + 50 \sin (3\omega t + \pi/3) + 2 \sin (\omega t + 5\pi/6)$  is applied to a series circuit of resistance  $20 \Omega$  and inductance  $0.05 \text{ H}$ . Derive (a) an expression for the current (b) the r.m.s. value of the current and for the voltage (c) the total power supplied and (d) the power factor. Take  $\omega = 314 \text{ rad/s}$ . **(Electrical Circuits, Nagpur Univ. 1991)**

**Solution. For Fundamental**

$$X_1 = \omega L = 314 \times 0.05 = 15.7 \Omega; \quad Z_1 = 20 + j15.7 = 25.4 \angle 38.1^\circ \Omega$$

**For Third Harmonic**

$$X_3 = 3\omega L = 3 \times 15.7 = 47.1 \Omega; \quad Z_3 = 20 + j47.1 = 51.2 \angle 67^\circ \Omega$$

**For Fifth Harmonic**

$$X_5 = 5\omega L = 5 \times 15.7 = 78.5 \Omega; \quad Z_5 = 20 + j78.5 = 81 \angle 75.7^\circ \Omega$$

(a) Expression for the current is

$$i = \frac{250}{25.4} \sin(\omega t - 38.1^\circ) + \frac{50}{51.2} \sin(3\omega t + 60^\circ - 67^\circ) + \frac{20}{81} \sin(5\omega t + 150^\circ - 75.7^\circ)$$

$$\therefore i = 9.84 \sin(\omega t - 38.1^\circ) + 0.9 \sin(3\omega t - 7^\circ) + 0.25 \sin(5\omega t + 74.3^\circ)$$

$$(b) \text{ R.M.S. current } I = \sqrt{\frac{I_{1m}^2}{2} + \frac{I_{3m}^2}{2} + \frac{I_{5m}^2}{2}}$$

$$I^2 = \frac{9.84^2}{2} + \frac{0.9^2}{2} + \frac{0.25^2}{2} = 48.92$$

$$\therefore I = \sqrt{48.92} = \mathbf{6.99 \text{ A}}$$

$$\text{R.M.S. voltage } V = \sqrt{\frac{250^2}{2} + \frac{50^2}{2} + \frac{20^2}{2}} = \mathbf{180.8 \text{ V}}$$

$$(c) \text{ Total power } = I^2 R = 48.92 \times 20 = \mathbf{978 \text{ W}}$$

$$(d) \text{ Power factor } = \frac{\text{Watts}}{VI} = \frac{978}{180.8 \times 6.99} = \mathbf{0.773}$$

**Example 20.7.** An r.m.s. current of 5 A, which has a third harmonic content, is passed through a coil having a resistance of 1  $\Omega$  and an inductance of 10 mH. The r.m.s. voltage across the coil is 20 V. Calculate the magnitude of the fundamental and harmonic components of current if the fundamental frequency is  $300/2\pi$  Hz. Also, find the power dissipated.

**Solution. (i) Fundamental Frequency**

$$\omega = 300 \text{ rad/s}; X_L = 300 \times 10^{-2} = 3 \Omega \therefore Z_1 = 1 + j3 = 3.16 \angle 71.6^\circ \text{ ohm}$$

If  $V_1$  is the r.m.s. value of the fundamental voltage across the coil, then

$$V_1 = I_1 Z_1 = 3.16 I_1$$

**(ii) Third Harmonic**

$$X_3 = 3 \times 3 = 9 \Omega; Z_3 = 1 + j9 = 9.05 \angle 83.7^\circ \text{ ohm}; V_3 = I_3 Z_3 = 9.05 I_3$$

Since r.m.s. current of the complex wave is 5 A and r.m.s. voltage drop 20 V

$$5 = \sqrt{I_1^2 + I_3^2} \quad \text{and} \quad 20 = \sqrt{V_1^2 + V_3^2}$$

Substituting the values of  $V_1$  and  $V_3$ , we get,  $20 = [(3.16 I_1)^2 + (9.05 I_3)^2]^{1/2}$

Solving for  $I_1$  and  $I_3$ , we have  $I_1 = 4.8 \text{ A}$  and  $I_3 = 1.44 \text{ A}$

$$\text{Power dissipated} = I^2 R = 5^2 \times 1 = 25 \text{ W}$$

**Example 20.8.** An e.m.f. represented by the equation  $e = 150 \sin 314 t + 50 \sin 942 t$  is applied to a capacitor having a capacitance 20  $\mu\text{F}$ . What is the r.m.s. value of the charging current?

**Solution. For Fundamental**

$$X_{C1} = 1/\omega C = 10^6/20 \times 314 = 159; I_{1m} = E_{1m}/X_{C1} = 150/159 = 0.943 \text{ A}$$

**For Third Harmonic**

$$X_{C3} = 1/3\omega C = 159/3 = 53 \Omega \therefore I_{3m} = E_{3m}/X_{C3} = 50/53 = 0.943 \text{ A}$$

r.m.s. value of charging current,

$$I = \sqrt{\frac{I_{1m}^2}{2} + \frac{I_{3m}^2}{2}} = \sqrt{\frac{0.943^2}{2} + \frac{0.943^2}{2}}$$

or  $I = 0.943 \text{ A}$

**Example 20.9.** The voltage given by  $v = 100 \cos 314 t + 50 \sin (1570t - 30^\circ)$  is applied to a circuit consisting of a 10  $\Omega$  resistance, a 0.02 H inductance and a 50  $\mu\text{F}$  capacitor. Determine the instantaneous current through the circuit. Also find the r.m.s. value of the voltage and current.

**Solution. For Fundamental**

$$\omega = 314 \text{ rad/s}; X_L = 314 \times 0.02 = 6.28 \Omega$$

$$X_C = 10^6/314 \times 50 = 63.8 \Omega; X = X_L - X_C = 6.28 - 63.8 = -57.32 \Omega$$

$$Z = \sqrt{10^2 + (-57.32)^2} = 58.3 \Omega; I_{1m} = 100/58.3 = 1.71 \text{ A}$$

$$\phi_1 = \tan^{-1}(-57.32/10) = -80.2^\circ \text{ (lead)}; i_1 = 1.71 \cos(314t + 80.2^\circ)$$

**For Fifth Harmonic**

$$\text{Inductive reactance} = 5 X_L = 5 \times 6.28 = 31.4 \Omega$$

$$\text{Capacitive reactance} = X_C/5 = 63.8/5 = 12.76 \Omega$$

$$\text{Net reactance} = 31.4 - 12.76 = 18.64 \Omega$$

$$Z = \sqrt{10^2 + 18.64^2} = 21.2 \Omega$$

$$I_{5m} = 50/21.2 = 2.36 \text{ A}; \quad \phi_5 = \tan^{-1}(18.64/10) = 61.8^\circ \text{ (lag)}$$

$$i_5 = 2.36 \sin(1570t - 30^\circ - 61.8^\circ) = 2.36 \sin(1570t - 91.8^\circ)$$

Hence, total instantaneous current is

$$i = i_1 + i_5 = 1.71 \cos(314t + 80.2^\circ) + 2.36 \sin(1570t - 91.8^\circ)$$

$$\text{R.M.S. voltage} = \sqrt{\frac{100^2}{2} + \frac{50^2}{5}} = 79.2 \text{ V}$$

$$\text{R.M.S. current} = \sqrt{\frac{1.71^2}{2} + \frac{2.36^2}{2}} = 2.06 \text{ A}$$

**Example 20.10.** A  $6.36 \mu\text{F}$  capacitor is connected in parallel with a resistance of  $500 \Omega$  and the combination is connected in series with a  $500\text{-}\Omega$  resistor. The whole circuit is connected across an a.c. voltage given by  $e = 300 \sin \omega t + 100 \sin(3\omega t + \pi/6)$ .

If  $\omega = 314 \text{ rad/s}$ , find

(i) power dissipated in the circuit

(ii) an expression for the voltage across the series resistor

(iii) the percentage harmonic content in the resultant current.

**Solution. For Fundamental**

$$X_{C1} = \frac{1}{\omega C} = \frac{10^6}{314 \times 6.36} = 500 \Omega$$

The impedance of the whole series-parallel circuit is given by

$$Z_1 = 500 + \frac{500(j500)}{500 + j500} = 750 + j250 = 791 \angle 18.4^\circ$$

**For Third Harmonic**

$$X_{C3} = 1/3\omega C = 500/3 = 167 \Omega$$

$$\therefore Z_3 = 500 + \frac{500(j167)}{500 + j167} = 550 + j150 = 570 \angle 15.3^\circ$$

$$\therefore i = \frac{300}{791} \sin(\omega t + 18.4^\circ) + \frac{100}{570} \sin(3\omega t + 45.3^\circ)$$

$$= 0.397 \sin(\omega t + 18.4^\circ) + 0.175 \sin(3\omega t + 45.3^\circ)$$

$$(i) \text{ Power dissipated} = \frac{E_{1m} I_{1m}}{2} \cos \phi_1 + \frac{E_{3m} I_{3m}}{2} \cos \phi_3$$

Fig. 20.6

$$= \frac{300 \times 0.379}{2} \times \cos 18.4^\circ + \frac{100 \times 0.175}{2} \cos 15.3^\circ = \mathbf{62.4 \text{ W}}$$

(ii) The voltage drop across the series resistor would be

$$E_R = iR = 500[0.379 \sin(\omega t + 18.4^\circ) + 0.175 \sin(3\omega t + 45.3^\circ)]$$

$$e_R = \mathbf{189.5 \sin(\omega t + 18.4^\circ) + 87.5 \sin(3\omega t + 45.3^\circ)}$$

(iii) The percentage harmonic content of the current is  $= 87.5/189.5 \times 100 = \mathbf{46.2\%}$

**Example 20.11.** An alternating voltage of  $v = 1.0 \sin 500t + 0.5 \sin 1500t$  is applied across a capacitor which can be represented by a capacitance of  $0.5 \mu\text{F}$  shunted by a resistance of  $4,000 \Omega$ . Determine

(i) the r.m.s. value of the current    (ii) the r.m.s. value of the applied voltage

(iii) the p.f. of the circuit.

(Circuit Theory and Components, Madras Univ.)

**Solution. For Fundamental** [Fig. 20.7 (a)]

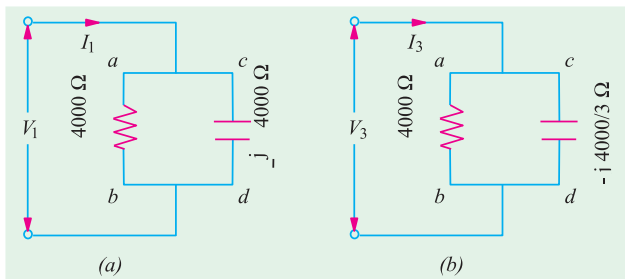

Fig. 20.7

$$V_1 = 1.0/\sqrt{2} = 0.707 \text{ V}$$

$$\text{Let, } V_1 = (0.707 + j0)$$

Capacitive reactance

$$= jX_{C1} = -j 10^6/500 \times 0.5$$

$$= j 4000 \Omega ; R = 4,000 \Omega$$

$$\therefore I_{ab1} = 0.707/4,000 = 0.177 \text{ mA}$$

$$I_{cd1} = 0.707/-j4,000 = j0.177 \text{ mA}$$

$$\therefore I_1 = 0.177 + j0.177$$

$$= 0.25 \angle 45^\circ \text{ mA}$$

Hence,  $I_1$  lead the fundamental voltage by  $45^\circ$ .

$$P_{ab1} = 0.707 \times 0.177 = 0.125 \text{ mW} ; P_{cd1} = 0$$

**For Third Harmonic** [Fig. 20.7 (b)]

$$V_3 = 0.5/\sqrt{2} = 0.3535 \angle 0^\circ ; R = 4,000 \Omega ; X_{C3} = -j4,000/3 \Omega$$

$$I_{ab3} = 0.3535/4000 = 0.0884 \angle 0^\circ \text{ mA} ; I_{cd3} = 0.3535/-j(4,000/3) = j 0.265 \text{ mA}$$

$$I_3 = 0.0884 + j0.265 = 0.28 \angle 71.6^\circ \text{ mA}$$

$$P_{ab3} = 0.3535 \times 0.0884 = 0.0313 \text{ mW} ; P_{cd3} = 0$$

$$(i) \text{ R.M.S. current} = \sqrt{I_1^2 + I_3^2} = \sqrt{0.25^2 + 0.28^2} = \mathbf{0.374 \text{ mA}}$$

$$(ii) \text{ R.M.S. voltage} = \sqrt{(1/\sqrt{2})^2 + (0.5/\sqrt{2})^2} = \mathbf{0.79 \text{ V}}$$

(iii) Power factor = watts/voltampere

$$\text{Wattage} = (0.125 + 0.0313) \times 10^{-3} = 0.1563 \times 10^{-3} \text{ W}$$

$$\text{Volt-amperes} = 0.79 \times 0.374 = 0.295 ; \text{p.f.} = 0.1563 \times 10^{-3}/0.295 = \mathbf{0.0005}$$

## 20.8. Selective Resonance due to Harmonics

When a complex voltage is applied across a circuit containing both inductance and capacitance, it may happen that the circuit resonates at one of the harmonic frequencies of the applied voltage. This phenomenon is known as **selective resonance**.

If it is a series circuit, then large currents would be produced at resonance, even though the applied voltage due to this harmonic may be small. Consequently, it would result in large harmonic voltage appearing across both the capacitor and the inductance.

If it is a parallel circuit, then at resonant frequency, the resultant current drawn from the supply would be minimum.

It is because of the possibility of such selective resonance happening that every effort is made to eliminate harmonics in supply voltage.

However, the phenomenon of selective resonance has been usefully employed in some wave analyses for determining the harmonic content of alternating waveforms. For this purpose, a variable inductance, a variable capacitor, a variable non-inductive resistor and a fixed non-inductive resistance or shunt for an oscillograph are connected in series and connected to show the wave-form of the voltage across the fixed non-inductive resistance. The values of inductance and capacitance are adjusted successively to give resonance for the first, third, first and seventh harmonics and a record of the waveform is obtained by the oscillograph. A quick inspection of the shape of the waveform helps to detect the presence or absence of a particular harmonic.

**Example 20.12.** An e.m.f.  $e = 200 \sin \omega t + 40 \sin 3 \omega t + 10 \sin 5 \omega t$  is impressed on a circuit comprising of a resistance of  $10 \Omega$ , a variable inductor and a capacitance of  $30 \mu\text{F}$ , all connected in series. Find the value of the inductance which will give resonance with triple frequency component of the pressure and estimate the effective p.f. of the circuit,  $\omega = 300$  radian/second. **(Elect. Engg. I, Bombay Univ.)**

**Solution.** For resonance at third harmonic

$$3\omega L = 1/3\omega C \quad \therefore L = 1/9\omega^2 C = 10^6/9 \times 300^2 \times 30 = \mathbf{0.041 \text{ H}}$$

$$Z_1 = 10 - j 300 \cdot 0.041 \frac{10^6}{300 \cdot 30} = 10 + j(12.3 - 111.1) = 10 - j98.8 = 99.3 \angle -84.2^\circ$$

$$Z_3 = 10 - j 3 L \frac{1}{3 C} = 10 - j(36.9 - 37.0) = 10 \angle 0^\circ$$

$$Z_5 = 10 - j 5 L \frac{1}{5 L} = 10 - j(61.5 - 22.2) = 10 - j39.3 = 40.56 \angle 75.7^\circ$$

$$I_{1m} = 200/99.3 = 2.015 \text{ A}; I_{3m} = 40/10 = 4 \text{ A}; I_{5m} = 10/40.56 = 0.246 \text{ A}$$

$$I = \sqrt{\frac{2.015^2}{2} + \frac{4^2}{2} + \frac{0.246^2}{2}} = \sqrt{10.06} = 3.172 \text{ A}$$

$$V = \sqrt{\frac{200^2}{2} + \frac{40^2}{2} + \frac{10^2}{2}} = 144.5 \text{ V}; \text{ Power} = I^2 R = 10.06 \times 10 = 100.6 \text{ W}$$

$$\text{Volt-amperes } VI = 144.5 \times 3.172 = 458 \text{ VA}; \text{ Power factor} = 100.6/458 = \mathbf{0.22}$$

**Example 20.13.** A coil having  $R = 100 \Omega$  and  $L = 0.1 \text{ H}$  is connected in series with a capacitor across a supply, the voltage of which is given by  $e = 200 \sin 314t + 5 \sin 3454t$ . What capacitance would be required to produce resonance with the 11th harmonic. Find (a) the equation of the current and (b) the r.m.s. value of the current, if this capacitance is in circuit.

**Solution.** For series resonance,  $X_L = X_C$

Since resonance is required for 11th harmonic whose frequency is 3454 rad/s, hence

$$3454L = \frac{1}{3454C}; C = \frac{1}{3454^2 \times 0.1} \text{ farad} = \mathbf{0.838 \mu\text{F}}$$

**(a) For Fundamental**

$$\text{Inductive reactance} = \omega L = 314 \times 0.1 = 31.4 \Omega$$

$$\text{Capacitive reactance} = 1/\omega C = 10^6 / 0.836 \times 314 = 3796 \Omega$$

$\therefore$  Net reactance =  $3796 - 31.4 = 3765 \ \Omega$ ; Resistance =  $100 \ \Omega$

$\therefore Z_1 = \sqrt{100^2 + 3765^2} = 3767 \ \Omega$ ;  $\tan \phi_1 = 3765/100 = 37.65$

$\therefore \phi_1 = 88^\circ 28'$  (leading) = 1.546 radian

Now  $E_{1m} = 200 \text{ V}$ ;  $Z_1 = 3767 \ \Omega \quad \therefore I_{1m} = 200/3767 = 0.0531 \text{ A}$

### Eleventh Harmonic

New reactance = 0; Impedance  $Z_{11} = 100 \ \Omega$

$\therefore$  Current  $I_{11m} = 5/100 = 0.05 \text{ A}$ ;  $\phi_{11} = 0$

... at resonance

Hence, the equation of the current is

$$i = \frac{200}{3767} (\sin 314t + 1.546) + \frac{5}{100} \sin(3454t + 0)$$

$$i = 0.0531 \sin(314t + 1.546) + 0.05 \sin 3454t$$

$$(b) I = \sqrt{(0.0531)^2/2 + (0.05)^2/2} = 0.052 \text{ A}$$

## 20.9. Effect of Harmonics on Measurement of Inductance and Capacitance

Generally, with the help of ammeter and voltmeter readings, the value of impedance, inductance and capacitance of a circuit can be calculated. But while dealing with complex voltages, the use of instrument readings does not, in general, give correct values of inductance and capacitance except in the case of a circuit containing only pure resistance. It is so because, in the case of resistance, the voltage and current waveforms are similar and hence the values of r.m.s. volts and r.m.s. amperes (as read by the voltmeter and ammeter respectively) would be the same whether they were sinusoidal or non-sinusoidal (*i.e.* complex).

### (i) Effect on Inductances

Let  $L$  be the inductance of a circuit and  $E$  and  $I$  the r.m.s. values of the applied voltage and current as read by the instruments connected in the circuit. For a complex voltage

$$E = 0.707 \sqrt{E_{1m}^2 + E_{3m}^2 + E_{5m}^2 + \dots}$$

$$\text{Hence } I = 0.707 \sqrt{\frac{E_{1m}^2}{L} + \frac{E_{3m}^2}{3L} + \frac{E_{5m}^2}{5L} + \dots}$$

$$\frac{0.707}{L} \sqrt{E_{1m}^2 + \frac{1}{9}E_{3m}^2 + \frac{1}{25}E_{5m}^2 + \dots}$$

$$\therefore L = \frac{0.707}{I} \sqrt{E_{1m}^2 + \frac{1}{9}E_{3m}^2 + \frac{1}{25}E_{5m}^2 + \dots}$$

For calculating the value of  $L$  from the above expression, it is necessary to know the absolute value of the amplitudes of several harmonic voltages. But, in practice, it is more convenient to deal with relative values than with absolute values. For this purpose, let us multiply and divide the right-hand side of the above expression by  $E$  but write the  $E$  **in the denominator** in its form  $0.707 \sqrt{E_{1m}^2 + E_{3m}^2 + E_{5m}^2 + \dots}$

$$\therefore L = \frac{0.707}{I} \sqrt{E_{1m}^2 + \frac{1}{9}E_{3m}^2 + \frac{1}{25}E_{5m}^2 + \dots} \times \frac{E}{0.707 \sqrt{E_{1m}^2 + E_{3m}^2 + E_{5m}^2 + \dots}}$$

$$\text{or } L = \frac{E}{I} \sqrt{\frac{E_{1m}^2}{(E_{1m}^2)} + \frac{1/9 E_{3m}^2}{E_{3m}^2} + \frac{1/25 E_{5m}^2}{E_{5m}^2} + \dots} = \frac{E}{I} \sqrt{\frac{1}{1} + \frac{1/9 (E_{3m}/E_{1m})^2}{(E_{3m}/E_{1m})^2} + \frac{1/25 (E_{5m}/E_{1m})^2}{(E_{5m}/E_{1m})^2} + \dots}$$

If the effect of harmonics were to be neglected, then the value of the inductance would appear to be  $E/\omega I$  but the true or actual value is less than this. The apparent value has to be multiplied by the quantity under the radical to get the true value of inductance when harmonics are present.

The quantity under the radical is called the correction factor *i.e.*

True inductance ( $L$ ) = Apparent inductance ( $L'$ )  $\times$  correction factor

### (ii) Effect on Capacitance

Let the capacitance of the circuit be  $C$  farads and  $E$  and  $I$  the instrument readings for voltage and current. Since the instruments read r.m.s. values, hence, as before,

$$E = 0.707 \sqrt{(E_{1m}^2 + E_{3m}^2 + E_{5m}^2 + \dots)}$$

$$\begin{aligned} \text{Hence } I &= 0.707 \sqrt{\frac{E_{1m}^2}{1/C} + \frac{E_{3m}^2}{1/3C} + \frac{E_{5m}^2}{1/5C} + \dots} \\ &= 0.707 \sqrt{(\omega C E_{1m})^2 + (3\omega C E_{3m})^2 + (5\omega C E_{5m})^2 + \dots} \\ &= 0.707 \omega C \sqrt{E_{1m}^2 + 9E_{3m}^2 + 25E_{5m}^2 + \dots} \end{aligned}$$

$$\therefore C = \frac{I}{0.707 \omega \sqrt{(E_{1m}^2 + 9E_{3m}^2 + 25E_{5m}^2 + \dots)}}$$

Again, we will multiply and divide the right-hand side  $E$  but in this case, we will write  $E$  in the numerator in its form  $[0.707 \sqrt{(E_{1m}^2 + E_{3m}^2 + E_{5m}^2 + \dots)}]$

$$\therefore C = \frac{1}{0.707 E \sqrt{(E_{1m}^2 + 9E_{3m}^2 + 25E_{5m}^2 + \dots)}} = \frac{1}{0.707 \sqrt{(E_{1m}^2 + 9E_{3m}^2 + 25E_{5m}^2 + \dots)}} \times \frac{1}{E}$$

$$\frac{1}{E} \sqrt{\frac{E_{1m}^2}{E_{1m}^2} + \frac{E_{3m}^2}{9E_{3m}^2} + \frac{E_{5m}^2}{25E_{5m}^2} + \dots} = \frac{1}{E} \sqrt{\frac{1}{1} + \frac{(E_{3m}/E_{1m})^2}{9(E_{3m}/E_{1m})^2} + \frac{(E_{5m}/E_{1m})^2}{25(E_{5m}/E_{1m})^2} + \dots}$$

Again, if the effects of harmonics were neglected, the value of capacitance would appear to be  $I/\omega E$  but its true value is less than this. For getting the true value, this apparent value will have to be multiplied by the quantity under the radical (which, therefore, is referred to as correction factor).\*

$\therefore$  True capacitance ( $C$ ) = Apparent capacitance ( $C'$ )  $\times$  correction factor

**Example 20.14.** A current of 50-Hz containing first, third and fifth harmonics of maximum values 100, 15 and 12 A respectively, is sent through an ammeter and an inductive coil of negligibly small resistance. A voltmeter connected to the terminals shows 75 V. What would be the current indicated by the ammeter and what is the exact value of the inductance of the coil in henrys?

\* It may be noted that this correction factor is different from that in the case of pure inductance.

**Solution.** The r.m.s. current is

$$I = 0.707\sqrt{I_{1m}^2 + I_{3m}^2 + I_{5m}^2} = 0.707\sqrt{(100^2 + 15^2 + 12^2)} = 72 \text{ A}$$

Hence, current indicated by the ammeter is **72 A**

$$\text{Now } E = 0.707\sqrt{(E_{1m}^2 + E_{3m}^2 + E_{5m}^2)}$$

$$\text{Also } I_{1m} = \frac{E_{1m}}{\omega L}; I_{3m} = \frac{E_{3m}}{3\omega L}; I_{5m} = \frac{E_{5m}}{5\omega L}$$

$$\therefore E_{1m} = I_{1m} \cdot \omega L; E_{3m} = I_{3m} \cdot 3\omega L; E_{5m} = I_{5m} \cdot 5\omega L$$

$$\therefore E = 0.707\sqrt{(I_{1m}\omega L)^2 + (I_{3m}3\omega L)^2 + (I_{5m}5\omega L)^2} = 0.707\omega L\sqrt{I_{1m}^2 + 9I_{3m}^2 + 25I_{5m}^2}$$

$$\therefore 75 = 0.707L \times 2\pi \times 50 \sqrt{100^2 + 9 \times 15^2 + 25 \times 12^2}$$

$$\therefore L = \mathbf{0.0027 \text{ H}}$$

$$\text{Note. Apparent inductance } L' = \frac{E}{\omega I} = \frac{75}{2\pi \times 50 \times 72} = 0.00331 \text{ H}$$

**Example 20.15.** The capacitance of a  $20 \mu\text{F}$  capacitor is checked by direct connection to an alternating voltage which is supposed to be sinusoidal, an electrostatic voltmeter and a dynamometer ammeter being used for measurement. If the voltage actually follows the law,

$$e = 100 \sin 250 t + 20 \sin (500 t - \phi) + 10 \sin (750 t - \phi)$$

Calculate the value of capacitance as obtained from the direct ratio of the instrument readings.

**Solution.** True value,  $C = 20 \mu\text{F}$

Apparent value  $C' =$  value read by the instruments

Now,  $C = C' \times$  correction factor.

Let us find the value of correction factor.

$$\text{Here } E_{1m} = 100; E_{2m} = 20 \text{ and } E_{3m} = 10$$

$$\therefore \text{Correction factor} = \sqrt{\frac{E_{1m}^2}{E_{1m}^2} \frac{E_{2m}^2}{4E_{2m}^2} \frac{E_{3m}^2}{9E_{3m}^2}} = \sqrt{\frac{100^2}{100^2} \frac{20^2}{4 \cdot 20^2} \frac{10^2}{9 \cdot 10^2}} = 0.9166$$

$$20 = C' \times 0.9166$$

$$\therefore C' = 20 / 0.9166 = \mathbf{21.82 \mu\text{F}}$$

## 21.10. Harmonics in Different Three-phase Systems

In three-phase systems, harmonics may be produced in the same way as in single-phase systems.

Hence, for all calculation they are treated in the same manner *i.e.* each harmonic is treated separately. Usually, even harmonics are absent in such systems. But care must be exercised when dealing with odd, especially, third harmonics and all multiples of 3rd harmonic (also called the triple- $n$  harmonics).

**(a) Expressions for Phase E.M.Fs.**

Let us consider a 3-phase alternator having identical phase windings ( $R$ ,  $Y$  and  $B$ ) in which harmonics are produced. The three phase e.m.fs. would be represented in their proper phase sequence by the equation.

$$e_R = E_{1m}(\omega t + \Psi_1) + E_{3m}(3\omega t + \Psi_3) + E_{5m} \sin(5\omega t + \Psi_5) + \dots$$

$$e_Y = E_{1m} \sin \left( t \frac{2}{3} \right) + E_{3m} \sin \left( 3 t \frac{2}{3} \right) + E_{5m} \sin \left( 5 t \frac{2}{3} \right) + \dots$$

$$e_B = E_{1m} \sin \left( t \frac{4}{3} \right) + E_{3m} \sin \left( 3 t \frac{4}{3} \right) + E_{5m} \sin \left( 5 t \frac{4}{3} \right) + \dots$$

On simplification, these become

$$e_R = E_{1m} \sin(\omega t + \Psi_1) + E_{3m}(3\omega t + \Psi_3) + E_{5m} \sin(5\omega t + \Psi_5) + \dots \quad \text{— as before}$$

$$e_Y = E_{1m} \sin \left( t \frac{2}{3} \right) + E_{3m} \sin \left( 3 t \frac{2}{3} \right) + E_{5m} \sin \left( 5 t \frac{10}{3} \right) + \dots$$

$$E_{1m} \sin \left( t \frac{2}{3} \right) + E_{3m} \sin \left( 3 t \frac{2}{3} \right) + E_{5m} \sin \left( 5 t \frac{4}{3} \right) + \dots$$

$$e_B = E_{1m} \sin \left( t \frac{4}{3} \right) + E_{3m} \sin \left( 3 t \frac{4}{3} \right) + E_{5m} \sin \left( 5 t \frac{2}{3} \right) + \dots$$

From these expressions, it is clear that

- (i) All third harmonics are equal in all phases of the circuit *i.e.* they are in time phase.
- (ii) Fifth harmonics in the three phases have a negative phase sequence of  $R, B, Y$  because the fifth harmonic of blue phase reaches its maximum value before that in the yellow phase.
- (iii) All harmonics which are not multiples of three, have a phase displacement of  $120^\circ$  so that they can be dealt with in the usual manner.
- (iv) At any instant, all the e.m.fs. have the same direction which means that in the case of a  $Y$ -connected system they are directed either away from or towards the neutral point and in the case of  $\Delta$ -connected system, they flow in the same direction.

Main points can be summarized as below :

- (i) all triple- $n$  harmonics *i.e.* 3rd, 9th, 15th etc. are in phase,
- (ii) the 7th, 13th and 19th harmonics have positive phase rotation of  $R, Y, B$ .
- (iii) the 5th, 11th and 17th harmonics have a negative phase sequence of  $R, B, Y$ .

**(b) Line Voltage for a Star-connected System**

In this system, the line voltages will be the **difference** between successive phase voltages and hence will contain no third harmonic terms because they, being identical in each phase, will cancel out. The fundamental will have a line voltage  $\sqrt{3}$  times the phase voltage. Also, fifth harmonic has line voltage  $\sqrt{3}$  its phase voltage.

But it should be noted that in this case the r.m.s. value of the line voltage will be less than  $\sqrt{3}$  times the r.m.s. value of the phase voltage due to the absence of third harmonic term from the line voltage. It can be proved that for any line voltage.

$$\text{Line value} = \sqrt{3} \sqrt{\frac{E_1^2 + E_5^2 + E_7^2}{E_1^2 + E_3^2 + E_5^2 + E_7^2}}$$

where  $E_1, E_3$  etc. are r.m.s. values of the phase e.m.fs.

**(c) Line Voltage for a  $\Delta$ -connected System**

If the winding of the alternator are delta-connected, then the resultant e.m.f. acting round the closed mesh would be the sum of the phase e.m.fs. The sum of these e.m.fs. is zero for fundamental, 5th, 7th, 11th etc. harmonics. Since the third harmonics are in phase, there will be a resultant third harmonic e.m.f. of three times the phase value acting round the closed mesh. It will produce a circulating current whose value will depend on the impedance of the windings at the third harmonic frequency. It means that the third harmonic e.m.f. would be short-circuited by the windings with the result that there will be no third harmonic voltage across the lines. The same is applicable to all triple- $n$  harmonic voltages. Obviously, the line voltage will be the phase voltage but without the triple- $n$  terms.

**Example 20.16.** A 3- $\phi$  generator has a generated e.m.f. of 230 V with 15 per cent third harmonic and 10 per cent fifth harmonic content. Calculate

(i) the r.m.s. value of line voltage for Y-connection.

(ii) the r.m.s. value of line voltage for  $\Delta$ -connection.

**Solution.** Let  $E_1, E_3, E_5$  be the r.m.s. values of the phase e.m.fs. Then

$$E_3 = 0.15 E_1 \text{ and } E_5 = 0.1 E_1$$

$$\therefore 230 = \sqrt{E_1^2 + (0.15E_1)^2 + (0.1E_1)^2}$$

$$E_1 = 226 \text{ V} \quad \therefore E_3 = 0.15 \times 226 = 34 \text{ V} \text{ and } E_5 = 0.1 \times 226 = 22.6 \text{ V}$$

(i) r.m.s. value of the fundamental line voltage =  $\sqrt{3} \times 226 = 392 \text{ V}$

r.m.s. value of third harmonic line voltage = 0

r.m.s. value of 5th harmonic line voltage  $\sqrt{3} \times 22.6 = 39.2 \text{ V}$

$$\therefore \text{r.m.s. value of line voltage } V_L = \sqrt{392^2 + 39.2^2} = 394 \text{ V}$$

(ii) In  $\Delta$ -connection, again the third harmonic would be absent from the line voltage

$$\therefore \text{r.m.s. value of line voltage } V_L = \sqrt{226^2 + 22.6^2} = 227.5 \text{ V}$$

**(d) Circulating Current in  $\Delta$ -connected Alternator**

Let the three symmetrical phase e.m.fs. of the alternator be represented by the equations,

$$e_R = E_{1m} \sin(\omega t + \Psi_1) + E_{3m} \sin(3\omega t + \Psi_3) + E_{5m} \sin(5\omega t + \Psi_5) + \dots$$

$$e_Y = E_{1m} \sin(\omega t + \Psi_1 - 2\pi/3) + E_{3m} \sin(3\omega t + \Psi_3) + E_{5m} \sin(5\omega t + \Psi_5 - 4\pi/3) + \dots$$

$$e_B = E_{1m} \sin(\omega t + \Psi_1 - 4\pi/3) + E_{3m} \sin(3\omega t + \Psi_3) + E_{5m} \sin(5\omega t + \Psi_5 - 2\pi/3) + \dots$$

The resultant e.m.f. acting round the  $\Delta$ -connected windings of the armature is the sum of these e.m.fs. Hence it is given by  $e = e_R + e_Y + e_B$

$$\therefore e = 3E_{3m} \sin(3\omega t + \Psi_3) + 3E_{9m} \sin(9\omega t + \Psi_9) + 3E_{15m} \sin(15\omega t + \Psi_{15}) + \dots$$

If  $R$  and  $L$  represent respectively the resistance and inductance per phase of the armature winding, then the circulating current due to the resultant e.m.f. is given by

$$i_c = \frac{3E_{3m} \sin(3\omega t + \Psi_3)}{3\sqrt{(R^2 + 9L^2\omega^2)}} + \frac{3E_{9m} \sin(9\omega t + \Psi_9)}{3\sqrt{(R^2 + 81L^2\omega^2)}} + \frac{3E_{15m} \sin(15\omega t + \Psi_{15})}{3\sqrt{(R^2 + 225L^2\omega^2)}} + \dots$$

$$= \frac{E_{3m} \sin(3\omega t + \Psi_3)}{\sqrt{(R^2 + 9L^2\omega^2)}} + \frac{E_{9m} \sin(9\omega t + \Psi_9)}{\sqrt{(R^2 + 81L^2\omega^2)}} + \frac{E_{15m} \sin(15\omega t + \Psi_{15})}{\sqrt{(R^2 + 225L^2\omega^2)}}$$

The r.m.s. value of the current is given by

$$I_C = 0.707 \sqrt{[E_{3m}^2 / (R^2 + 9L^2\omega^2) + E_{9m}^2 / (R^2 + 81L^2\omega^2) + (E_{15m}^2 / (R^2 + 225L^2\omega^2) + \dots)]}$$

### (e) Three-phase four-wire System

In this case, there will be no third harmonic component in line voltage. For the 4-wire system, each phase voltage (*i.e.* line to neutral) may contain a third harmonic component. If it is actually present, then current will flow in the *Y*-connected load. In case load is balanced, the resulting third harmonic line currents will all be in phase so that neutral wire will have to carry three times the third harmonic line current. There will be no current in the neutral wire either at fundamental frequency, or any harmonic frequency other than the triple-*n* frequency.

## 20.11. Harmonics in Single and 3-phase Transformers

The flux density in transformer core is usually maintained at a fairly high value in order to keep the required volume of iron to the minimum. However, due to the non-linearity of magnetisation curve, some third harmonic distortion is always produced. Also, there is usually a small percentage of fifth harmonic. The magnetisation current drawn by the primary contains mainly third harmonic whose proportion depends on the size of the primary applied voltage. Hence, the flux is sinusoidal.

In the case of three-phase transformers, the production of harmonics will be affected by the method of connection and the type of construction employed.

3-phase current transformer

### (a) Primary Windings $\Delta$ -CONNECTED

Each primary phase can be considered as separately connected across the sinusoidal supply.

(i) The core flux will be sinusoidal which means that magnetizing current will contain 3rd harmonic component in addition to relatively small amounts of other harmonics of higher order.

(ii) In each phase, these third harmonic currents will be in phase and so produce a circulating current round the mesh with the result that there will be no third harmonic component in the line current.

### (b) Primary Winding Connected in 4-wire Star

Each phase of the primary can again be considered as separately connected across a sinusoidal supply.

- (j) The flux in the transformer core would be sinusoidal and so would be the output voltage.
- (ii) The magnetizing current will contain 3rd harmonic component. This component being in phase in each winding will, therefore, return through the neutral wire.

**(c) Primary Windings Connected 3-wire Star**

Since there is no neutral wire, there will be no return path for the 3rd harmonic component of the magnetizing current. Hence, there will exist a condition of forced magnetization so that core flux must contain third harmonic component which is in phase in each limb of the transformer core. Although there will be a magnetic path for these fluxes in the case of shell type 3-phase transformer, yet in the case of three-limb core type transformer, the third harmonic component of the flux must return *via* the air. Because of the high reluctance magnetic path in such transformers, the third harmonic flux is reduced to a very small value. However, if the secondary of the transformer is delta-connected, then a third harmonic circulating current would be produced. This current would be in accordance with Lenz's law tend to oppose the very cause producing it *i.e.* it would tend to minimize the third harmonic component of the flux.

Should the third and fifth secondary be *Y*-connected, then provision of an additional  $\Delta$ -connected winding, in which this current can flow, becomes necessary. This tertiary winding additionally served the purpose of preserving magnetic equilibrium of the transformer in the case of unbalanced loads. In this way, the output voltage from the secondary can be kept reasonably sinusoidal.

**Example 20.17.** Determine whether the following two waves are of the same shape

$$e = 10 \sin (\omega t + 30^\circ) - 50 \sin (3 \omega t - 60^\circ) + 25 \sin (5 \omega t + 40^\circ)$$

$$i = 1.0 \sin (\omega t - 60^\circ) + 5 \sin (3 \omega t - 150^\circ) + 2.5 \cos (5 \omega t - 140^\circ)$$

(Principles of Elect. Engg-II Jadavpur Univ.)

**Solution.** Two waves possess the same waveshape

- (i) if they contain the same harmonics
- (ii) if the ratio of the corresponding harmonics to their respective fundamentals is the same
- (iii) if the harmonics are similarly spaced with respect to their fundamentals.

In other words,

- (a) the ratio of the magnitudes of corresponding harmonics must be constant and
- (b) with fundamentals in phase, the corresponding harmonics of the two waves must be in phase.

The test is applied first by checking the ratio of the corresponding harmonics and then coinciding the fundamentals by shifting one wave. If the phase angles of the corresponding harmonics are the same, then the two waves have the same shape.

In the present case, condition (i) is fulfilled because the voltage and current waves contain the same harmonics, *i.e.* third and fifth.

Secondly, the ratio of the magnitude of corresponding current and voltage harmonics is the same *i.e.* 1/10.

Now, let the fundamental of the current wave be shifted ahead by  $90^\circ$  so that it is brought in phase with the fundamental of the voltage wave. It may be noted that the third and fifth harmonics of the current wave will be shifted by  $3 \times 90^\circ = 270^\circ$  and  $5 \times 90^\circ = 450^\circ$  respectively. Hence, the current wave becomes

$$i' = 1.0 \sin (\omega t - 60^\circ + 90^\circ) + 5 \sin (3\omega t - 150^\circ + 270^\circ) + 2.5 \cos (5\omega t - 140^\circ + 450^\circ)$$

$$= 1.0 \sin (\omega t + 30^\circ) + 5 \sin (3\omega t + 120^\circ) + 2.5 \cos (5\omega t + 310^\circ)$$

$$= 1.0 \sin(\omega t + 30^\circ) - 5 \sin(3\omega t - 60^\circ) + 2.5 \sin(5\omega t + 40^\circ)$$

It is seen that now the corresponding harmonics of the voltage and current waves are in phase. Since all conditions are fulfilled, the two waves are of the same waveshape.

### Tutorial Problem No. 20.1

1. A series circuit consist of a coil of inductance 0.1 H and resistance 25  $\Omega$  and a variable capacitor. Across this circuit is applied a voltage whose instantaneous value is given by

$$v = 100 \sin \omega t + 20 \sin(3\omega t - 45) + 5 \sin(5\omega t - 30) \text{ where } \omega = 314 \text{ rad / s}$$

Determine the value of  $C$  which will produce response at third harmonic frequency and with this value of  $C$ , find

(a) an expression for the current in the circuit (b) the r.m.s. value of this current (c) the total power absorbed.

$$[11.25 \mu\text{F}, (a) i = 0.398 \sin(\omega t + 84.3) + 0.8 \sin(3\omega t + 45) + 0.485 \sin(5\omega t + 106) (b) 0.633 \text{ A} (c) 10 \text{ W}]$$

2. A voltage given by  $v = 200 \sin 314 t + 520 \sin(942 t + 45^\circ)$  is applied to a circuit consisting of a resistance of 20  $\Omega$ , and inductance of 20 mH and a capacitance of 56.3  $\mu\text{F}$  all connected in series.

Calculate the r.m.s. values of the applied voltage and current. Find also the total power absorbed by the circuit.

$$[146 \text{ V} ; 3.16 \text{ A} ; 200 \text{ W}]$$

3. A voltage given by  $v = 100 \sin \omega t + 8 \sin 3\omega t$  is applied to a circuit which has a resistance of 1  $\Omega$ , an inductance of 0.02 H and a capacitance of 60  $\mu\text{F}$ . A hot-wire ammeter is connected in series with the circuit and a hot-wire voltmeter is connected to the terminals. Calculate the ammeter and voltmeter readings and the power supplied to the circuit.

$$[71 \text{ V} ; 5.18 \text{ A} ; 26.8 \text{ W}]$$

4. A certain coil has a resistance of 20  $\Omega$  and an inductance of 0.04 H. If the instantaneous current flowing in it is represented by  $i = 5 \sin 300 t + 0.8 \sin 900 t$  amperes, derive an expression for the instantaneous value of the voltage applied across the ends of the coil and calculate the r.m.s. value of that voltage.

$$[V = 117 \sin(300 t + 0.541) + 33 \sin(900 t + 1.06) ; 0.86 \text{ V}]$$

5. A voltage given by the equation  $v = \sqrt{2} 100 \sin 2\pi \times 50 t + \sqrt{2.20} \sin 2\pi \cdot 150 t$  is applied to the terminals of a circuit made up of a resistance of 5  $\Omega$ , an inductance of 0.0318 H and a capacitor of 12.5  $\mu\text{F}$  all in series. Calculate the effective current and the power supplied to the circuit.

$$[0.547 \text{ A} ; 1.5 \text{ W}]$$

6. An alternating voltage given by the expression  $v = 1,000 \sin 314 t + 100 \sin 942 t$  is applied to a circuit having a resistance of 100  $\Omega$  and an inductance of 0.5 H. Calculate r.m.s. value of the current and p.f.

$$[3.81 \text{ A} ; 0.535]$$

7. The current in a series circuit consisting of a 159  $\mu\text{F}$  capacitor, a reactor with a resistance of 10  $\Omega$  and an inductances of 0.0254 H is given by  $i = \sqrt{2}(8 \sin \omega t + 2 \sin 3\omega t)$  amperes. Calculate the power input and the power factor. Given  $\omega = 100\pi$  radian/second.

$$[680 \text{ W} ; 0.63]$$

8. If the terminal voltage of a circuit is  $100 \sin \omega t + 50 \sin(3\omega t + \pi/4)$  and the current is  $10 \sin(\omega t + \pi/3) + 5 \sin 3\omega t$ , calculate the power consumption.

$$[522.6 \text{ W}]$$

9. A single-phase load takes a current of  $4 \sin(\omega t + \pi/6) + 1.5 \sin(3\omega t + \pi/3)$  A from source represented by  $360 \sin \omega t$  volts. Calculate the power dissipated by the circuit and the circuit power factor.

$$[623.5 \text{ W} ; 0.837]$$

10. An e.m.f. given by  $e = 100 \sin \omega t + 40 \sin(\omega t - \pi/6) + 10 \sin(5\omega t - \pi/3)$  volts is applied to a series circuit having a resistance of  $100 \Omega$ , an inductance of  $40.6 \text{ mH}$  and a capacitor of  $10 \mu\text{F}$ . Derive an expression for the current in the circuit. Also, find the r.m.s. value of the current and the power dissipated in the circuit. Take  $\omega = 314 \text{ rad/second}$ .

[0.329 A, 10.8 W]

11. A p.d. of the form  $v = 400 \sin \omega t + 30 \sin 3\omega t$  is applied to a rectifier having a resistance of  $50 \Omega$  in one direction and  $200$  in the reverse direction. Find the average and effective values of the current and the p.f. of the circuit.

[1.96 A, 4.1 A, 0.51]

12. A coil having  $R = 2 \Omega$  and  $L = 0.01 \text{ H}$  carries a current given by  $i = 50 + 20 \sin 300 t$

A moving-iron ammeter, a moving-coil voltmeter and a dynamometer wattmeter, are used to indicate current, voltage and power respectively. Determine the readings of the instruments and equation for the p.d.

[121.1 V ; 52 A ; 5.4 kW,  $V = 100 + 72 \sin(300 t + 0.982)$ ]

13. Two circuits having impedances at  $50 \text{ Hz}$  of  $(10 + j6) \Omega$  and  $(10 - j6)$  respectively are connected in parallel across the terminals of an a.c. system, the waveform of which is represented by  $v = 100 \sin \omega t + 35 \sin 3\omega t + 10 \sin 5\omega t$ , the fundamental frequency being  $50 \text{ Hz}$ . Determine the ratio of the readings of two ammeters, of negligible resistance, connected one in each circuit.

[6.35 ; 6.72]

14. Explain what is meant by harmonic resonance in a.c. circuits.

A current having an instantaneous value of  $2(\sin \omega t + \sin 3\omega t)$  amperes is passed through a circuit which consists of a coil of resistance  $R$  and inductance  $L$  in series with a capacitor  $C$ . Derive an expression for the value of  $\omega$  at which the r.m.s. circuit voltage is a minimum. Determine the voltage if the coil has inductance  $0.1 \text{ H}$  and resistance  $150 \Omega$  and the capacitance is  $10 \mu\text{F}$ . Determine also the circuit voltage at the fundamental resonant frequency.

[ $\omega = 1/\sqrt{LC}$  ; 378 V ; 482 V]

15. An r.m.s. current of  $5 \text{ A}$  which has a third-harmonic content, is passed through a coil having a resistance of  $1 \Omega$  and an inductance of  $10 \text{ mH}$ . The r.m.s. voltage across the coil is  $20 \text{ V}$ . Calculate the magnitudes of the fundamental and harmonic components of current if the fundamental frequency is  $300/2\pi \text{ Hz}$ . Also, find the power dissipated.

[4.8 A ; 1.44 A ; 25 W]

16. Derive a general expression for the form factor of a complex wave containing only odd-order harmonics. Hence, calculate the form factor of the alternating current represented by

$$i = 2.5 \sin 157 t + 0.7 \sin 471 t + 0.4 \sin 785 t$$

[1.038]

## OBJECTIVE TESTS – 20

- Non-sinusoidal waveforms are made up of
  - different sinusoidal waveforms
  - fundamental and even harmonics
  - fundamental and odd harmonics
  - even and odd harmonics only.
- The positive and negative halves of a complex wave are symmetrical when
  - it contains even harmonics
  - phase difference between even harmonics and fundamental is  $0$  or  $\pi$
  - it contains odd harmonics
  - phase difference between even harmonics and fundamental is either  $\pi/2$  or  $3\pi/2$ .
- The r.m.s. value of the complex voltage given by  $v = 16\sqrt{2} \sin \omega t + 12\sqrt{2} \sin 3\omega t$  is

- (a)  $20\sqrt{2}$                       (b) 20  
(c)  $28\sqrt{2}$                       (d) 192
4. In a 3-phase system, \_\_\_th harmonic has negative phase sequence of RBY.  
(a) 9                                  (b) 13  
(c) 5                                  (d) 15
5. A complex current wave is given by the equation  $i = 14 \sin \omega t + 2 \sin 5\omega t$ . The r.m.s. value of the current is \_\_\_ ampere.  
(a) 16                                  (b) 12  
(c) 10                                  (d) 8
6. When a pure inductive coil is fed by a complex voltage wave, its current wave  
(a) has larger harmonic content  
(b) is more distorted  
(c) is identical with voltage wave  
(d) shows less distortion.
7. A complex voltage wave is applied across a pure capacitor. As compared to the fundamental voltage, the reactance offered by the capacitor to the third harmonic voltage would be  
(a) nine time                      (b) three times  
(c) one-third                      (d) one-ninth
8. Which of the following harmonic voltage components in a 3-phase system would be in phase with each other ?  
(a) 3rd, 9th, 15th etc.  
(b) 7th, 13th, 19th etc.  
(c) 5th, 11th, 17th etc.  
(d) 2nd, 4th, 6th etc.

**ANSWERS**

1. (a)   2. (c)   3. (b)   4. (c)   5. (c)   6. (d)   7. (c)   8. (d)

- Different Types of Functional Symmetries
- Line or Frequency Spectrum
- Procedure for Finding the Fourier Series of a Given Function
- Wave Analyzer
- Spectrum Analyzer
- Fourier Analyzer
- Harmonic Synthesis

## FOURIER SERIES

With the help of Fourier Theorem, it is possible to determine the magnitude, order and phase of the several harmonics present in a complex periodic wave

### 21.1. Harmonic Analysis

By harmonic analysis is meant the process of determining the magnitude, order and phase of the several harmonics present in a complex periodic wave.

For carrying out this analysis, the following methods are available which are all based on Fourier theorem:

(i) Analytical Method—the standard Fourier Analysis  
 (ii) Graphical Method— (a) by Superposition Method (Wedgemore' Method) (b) Twenty four Ordinate Method

(iii) Electronic Method—by using a special instrument called 'harmonic analyser'

We will consider the first and third methods only.

### 21.2. Periodic Functions

A function  $f(t)$  is said to be periodic if  $f(t+T) = f(t)$  for all values of  $t$  where  $T$  is some positive number. This  $T$  is the interval between two successive repetitions and is called the period of  $f(t)$ . A sine wave having a period of  $T = 2\pi / \omega$  is a common example of periodic function.

### 21.3. Trigonometric Fourier Series

Suppose that a given function  $f(t)$  satisfies the following conditions (known as Dirichlet conditions):

1.  $f(t)$  is periodic having a period of  $T$ .
2.  $f(t)$  is single-valued everywhere.
3. In case it is discontinuous,  $f(t)$  has a finite number of discontinuities in any one period.
4.  $f(t)$  has a finite number of maxima and minima in any one period.

The function  $f(t)$  may represent either a voltage or current waveform. According to Fourier theorem, this function  $f(t)$  may be represented in the trigonometric form by the infinite series.

$$f(t) = a_0 + a_1 \cos \omega_0 t + a_2 \cos 2\omega_0 t + a_3 \cos 3\omega_0 t + \dots + a_n \cos n\omega_0 t \\ + b_1 \sin \omega_0 t + b_2 \sin 2\omega_0 t + b_3 \sin 3\omega_0 t + \dots + b_n \sin n\omega_0 t$$

$$= a_0 + \sum_{n=1}^{\infty} (a_n \cos n\omega_0 t + b_n \sin n\omega_0 t)$$

... (i)

Putting  $\omega_0 t = \theta$ , we can write the above equation as under

$$f(\theta) = a_0 + a_1 \cos \theta + a_2 \cos 2\theta + a_3 \cos 3\theta + \dots + a_n \cos n\theta + b_1 \sin \theta + b_2 \sin 2\theta + b_3 \sin 3\theta + \dots + b_n \sin n\theta$$

$$= a_0 + \sum_{n=1}^{\infty} (a_n \cos n\theta + b_n \sin n\theta)$$

... (ii)

Since  $\omega_0 = 2\pi / T$ , Eq. (i) above can be written as

$$f(t) = a_0 + \sum_{n=1}^{\infty} \left( a_n \cos \frac{2\pi n}{T} t + b_n \sin \frac{2\pi n}{T} t \right)$$

... (iii)

where  $\omega_0$  is the fundamental angular frequency,  $T$  is the period and  $a_0, a_n$  and  $b_n$  are constants which depend on  $n$  and  $f(t)$ . The process of determining the values of the constants  $a_0, a_n$  and  $b_n$  is called Fourier Analysis. Also,  $\omega_0 = 2\pi / T = 2\pi f_0$  where  $f_0$  is the fundamental frequency.

It is seen from the above Fourier Series that the periodic function consists of sinusoidal components of frequency  $0, \omega_0, 2\omega_0, \dots, n\omega_0$ . This representation of the function  $f(t)$  is in the frequency domain. The first component  $a_0$  with zero frequency is called the *dc* component. The sine and cosine terms represent the harmonics. The number  $n$  represents the order of the harmonics.

When  $n = 1$ , the component  $(a_1 \cos \omega_0 t + b_1 \sin \omega_0 t)$  is called the first harmonic or the fundamental component of the waveform.

When  $n = 2$ , the component  $(a_2 \cos 2\omega_0 t + b_2 \sin 2\omega_0 t)$  is called the second harmonic of the waveform.

The  $n$ th harmonic of the waveform is represented by  $(a_n \cos n\omega_0 t + b_n \sin n\omega_0 t)$ . It has a frequency of  $n\omega_0$  i.e.  $n$  times the frequency of the fundamental component.

### 21.4. Alternate Forms of Trigonometric Fourier Series

Eq. (j) given above can be written as

$$f(t) = a_0 + (a_1 \cos \omega_0 t + b_1 \sin \omega_0 t) + (a_2 \cos 2\omega_0 t + b_2 \sin 2\omega_0 t) + \dots + (a_n \cos n\omega_0 t + b_n \sin n\omega_0 t)$$

Let,  $a_n \cos n\omega_0 t + b_n \sin n\omega_0 t = A_n \cos(n\omega_0 t - \phi_n)$

$$= A_n \cos n\omega_0 t \cos \phi_n + A_n \sin n\omega_0 t \sin \phi_n$$

$$\therefore a_n = A_n \cos \phi_n \text{ and } b_n = A_n \sin \phi_n$$

$$\therefore A_n = \sqrt{a_n^2 + b_n^2} \text{ and } \phi_n = \tan^{-1} b_n / a_n$$

Similarly, let  $(a_n \cos n\omega_0 t + b_n \sin n\omega_0 t = A_n \sin(n\omega_0 t + \Psi_n))$

$$= A_n \sin n\omega_0 t \cos \Psi_n + A_n \cos n\omega_0 t \sin \phi_n$$

As seen from Fig. 21.1,  $b_n = A_n \cos \psi_n$  and  $a_n = A_n \sin \psi_n$

$$\therefore A_n = \sqrt{a_n^2 + b_n^2} \text{ and } \psi_n = \tan^{-1} a_n / b_n$$

The two angles  $\phi_n$  and  $\psi_n$  are complementary angles.

Hence, the Fourier series given in Art. 21.2 may be put in the following two alternate forms

$$f(t) = A_0 + \sum_{n=1}^{\infty} A_n \cos(n\omega_0 t - \phi_n)$$

or  $f(t) = A_0 + \sum_{n=1}^{\infty} A_n \sin(n\omega_0 t + \psi_n)$

Fig. 21.1

### 21.5. Certain Useful Integral Calculus Theorems

The Fourier coefficients or constants  $a_0, a_1, a_2, \dots, a_n$  and  $b_1, b_2, \dots, b_n$  can be evaluated by integration process for which purpose the following theorems will be used.

$$(i) \int_0^{2\pi} \sin n\theta d\theta = \frac{1}{n} \left| \cos n\theta \right|_0^{2\pi} = \frac{1}{n} (1-1) = 0$$

$$(ii) \int_0^{2\pi} \cos n\theta d\theta = -\frac{1}{n} \left| \sin n\theta \right|_0^{2\pi} = -\frac{1}{n} (0-0) = 0$$

$$(iii) \int_0^{2\pi} \sin^2 n\theta d\theta = \frac{1}{2} \int_0^{2\pi} (1 - \cos 2n\theta) d\theta = \frac{1}{2} \left| \theta - \frac{\sin 2n\theta}{2n} \right|_0^{2\pi} = \pi$$

$$(iv) \int_0^{2\pi} \cos^2 n\theta d\theta = \frac{1}{2} \int_0^{2\pi} (\cos 2n\theta + 1) d\theta = \frac{1}{2} \left| \frac{\sin 2n\theta}{2n} + \theta \right|_0^{2\pi} = \pi$$

$$(v) \int_0^{2\pi} \sin m\theta \cos n\theta d\theta = \frac{1}{2} \int_0^{2\pi} \{ \sin(m+n)\theta - \sin(m-n)\theta \} d\theta$$

$$= \frac{1}{2} \left| -\frac{1}{m+n} \cos(m+n)\theta - \frac{1}{m-n} \cos(m-n)\theta \right|_0^{2\pi} = 0$$

$$(vi) \int_0^{2\pi} \cos m\theta \cos n\theta d\theta = \frac{1}{2} \int_0^{2\pi} \{ \cos(m+n)\theta + \cos(m-n)\theta \} d\theta$$

$$= \frac{1}{2} \left| \frac{1}{m+n} \sin(m+n)\theta + \frac{1}{m-n} \sin(m-n)\theta \right|_0^{2\pi} = 0 \dots \text{for } n \neq m$$

$$(vii) \int_0^{2\pi} \sin m\theta \sin n\theta d\theta = \frac{1}{2} \int_0^{2\pi} \{ \cos(m-n)\theta - \cos(m+n)\theta \} d\theta$$

$$= \frac{1}{2} \left| \frac{1}{m-n} \sin(m-n)\theta - \frac{1}{m+n} \sin(m+n)\theta \right|_0^{2\pi} = 0 \dots \text{for } n \neq m$$

where  $m$  and  $n$  are any positive integers.

### 21.6. Evaluation of Fourier Constants

Let us now evaluate the constants  $a_0, a_n$  and  $b_n$  by using the above integral calculus theorems

#### (i) Value of $a_0$

For this purpose we will integrate both sides of the series given below over one period *i.e.* for  $\theta = 0$  to  $\theta = 2\pi$ .

$$f(\theta) = a_0 + a_1 \cos \theta + a_2 \cos 2\theta + \dots + a_n \cos n\theta + b_1 \sin \theta + b_2 \sin 2\theta + \dots + b_n \sin n\theta$$

$$\therefore \int_0^{2\pi} f(\theta) d\theta = \int_0^{2\pi} a_0 d\theta + a_1 \int_0^{2\pi} \cos \theta d\theta + a_2 \int_0^{2\pi} \cos 2\theta d\theta + \dots + a_n \int_0^{2\pi} \cos n\theta d\theta$$

$$+ b_1 \int_0^{2\pi} \sin \theta d\theta + b_2 \int_0^{2\pi} \sin 2\theta d\theta + \dots + b_n \int_0^{2\pi} \sin n\theta d\theta$$

$$= a_0 \int_0^{2\pi} 1 d\theta = 0 + 0 + \dots + 0 + 0 + \dots + 0 = 2\pi a_0$$

$$\therefore a_0 = \frac{1}{2\pi} \int_0^{2\pi} f(\theta) d\theta \text{ or } = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\theta) d\theta$$

= mean value of  $f(\theta)$  between the limits 0 to  $2\pi$  i.e. over one cycle or period.

$$\text{Also, } a_0 = \frac{1}{2} [\text{net area}]_0^{2\pi}$$

If we take the periodic function as  $f(t)$  and integrate over period  $T$  (which corresponds to  $2\pi$ ),

$$\text{we get } a_0 = \frac{1}{T} \int_0^T f(t) dt = \frac{1}{T} \int_{-T/2}^{T/2} f(t) dt = \frac{1}{T} \int_{t_1}^{t_1+T} f(t) dt$$

where  $t_1$  can have any value.

### (ii) Value of $a_n$

For finding the value of  $a_n$ , multiply both sides of the Fourier Series by  $\cos n\theta$  and integrate between the limits 0 to  $2\pi$

$$\begin{aligned} \therefore \int_0^{2\pi} f(\theta) \cos n\theta d\theta &= a_0 \int_0^{2\pi} \cos n\theta d\theta + a_1 \int_0^{2\pi} \cos \theta \cos n\theta d\theta + a_2 \int_0^{2\pi} \cos 2\theta \cos n\theta d\theta \\ &+ a_n \int_0^{2\pi} \cos^2 n\theta d\theta + b_1 \int_0^{2\pi} \cos \theta \sin n\theta d\theta + b_2 \int_0^{2\pi} \sin 2\theta \cos n\theta d\theta + \dots + b_n \int_0^{2\pi} \sin n\theta \cos n\theta d\theta \\ &= 0 + 0 + 0 + \dots + a_n \int_0^{2\pi} \cos^2 n\theta d\theta + 0 + 0 + \dots + 0 = a_n \int_0^{2\pi} \cos^2 n\theta d\theta = \pi a_n \end{aligned}$$

$$\therefore a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta = 2 \times \frac{1}{2\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta$$

= 2 × average value of  $f(\theta) \cos n\theta$  over one cycle of the fundamental.

$$\text{Also, } a_n = \frac{1}{2} \int_0^{2\pi} f(\theta) \cos n\theta d\theta = \frac{1}{2} \int_0^{2\pi} f(\theta) \cos n\theta d\theta$$

If we take periodic function as  $f(t)$ , then different expressions for  $a_n$  are as under.

$$a_n = \frac{2}{T} \int_0^T f(t) \cos \frac{2\pi n}{T} t dt = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos \frac{2\pi n}{T} t dt$$

Giving different numerical values to  $n$ , we get

$$a_1 = 2 \times \text{average of } f(\theta) \cos \theta \text{ over one cycle} \quad \dots n = 1$$

$$a_2 = 2 \times \text{average value of } f(\theta) \cos 2\theta \text{ over one cycle etc.} \quad \dots n = 2$$

### (iii) Value of $b_n$

For finding its value, multiply both sides of the Fourier Series of Eq. (i) by  $\sin n\theta$  and integrate between limits  $\theta = 0$  to  $\theta = 2\pi$ .

$$\begin{aligned} \therefore \int_0^{2\pi} f(\theta) \sin n\theta d\theta &= a_0 \int_0^{2\pi} \sin n\theta d\theta + a_1 \int_0^{2\pi} \cos \theta \sin n\theta d\theta \\ &+ a_2 \int_0^{2\pi} \cos 2\theta \sin n\theta d\theta + \dots + a_n \int_0^{2\pi} \cos n\theta \sin n\theta d\theta \\ &+ b_1 \int_0^{2\pi} \sin \theta \sin n\theta d\theta + b_2 \int_0^{2\pi} \sin 2\theta \sin n\theta d\theta + \dots + b_n \int_0^{2\pi} \sin^2 n\theta d\theta \\ &= 0 + 0 + 0 + \dots + 0 + 0 + \dots + b_n \int_0^{2\pi} \sin^2 n\theta d\theta = b_n \int_0^{2\pi} \sin^2 n\theta d\theta = b_n \pi \end{aligned}$$

$$\therefore \int_0^{2\pi} f(\theta) \sin n\theta d\theta = b_n \times \pi$$

$$\therefore b_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta = 2 \times \frac{1}{2\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta$$

= 2 × average value of  $f(\theta) \sin n\theta$  over one cycle of the fundamental.

$$\therefore b_1 = 2 \times \text{average value of } f(\theta) \sin \theta \text{ over one cycle} \quad \dots n = 1$$

$$b_2 = 2 \times \text{average value of } f(\theta) \sin 2\theta \text{ over one cycle} \quad \dots n = 2$$

$$\text{Also, } b_n = \frac{2}{T} \int_0^T f(t) \sin \frac{2\pi n}{T} t dt + \frac{2}{T} \int_{T/2}^{T/2} f(t) \sin \frac{2\pi n}{T} t dt$$

$$= \frac{2}{T} \int_0^T f(t) \sin n\omega_0 t dt = \frac{2}{T} \int_{T/2}^{T/2} f(t) \sin n\omega_0 t dt$$

Hence, for Fourier analysis of a periodic function, the following procedure should be adopted:

(i) Find the term  $a_0$  by integrating both sides of the equation representing the periodic function between limits 0 to  $2\pi$  or 0 to  $T$  or  $-T/2$  to  $T/2$  or  $t_1$  to  $(t_1 + T)$ .

$$\therefore a_0 = \frac{1}{2\pi} \int_0^{2\pi} f(\theta) d\theta = \frac{1}{T} \int_0^T f(t) dt = \frac{1}{T} \int_{-T/2}^{T/2} f(t) dt = \frac{1}{T} \int_{t_1}^{t_1+T} f(t) dt$$

= average value of the function over one cycle.

(ii) Find the value of  $a_n$  by multiplying both sides of the expression for Fourier series by  $\cos n\theta$  and then integrating it between limits 0 to  $2\pi$  or 0 to  $T$  or  $-T/2$  to  $T/2$  or  $t_1$  to  $(t_1 + T)$ .

$$\therefore a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta = 2 \times \frac{1}{2\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta$$

Since  $\pi = T/2$ , we have

$$a_n = \frac{2}{T} \int_0^T f(t) \cos \frac{2\pi n}{T} t dt = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos \frac{2\pi n}{T} t dt = \frac{2}{T} \int_{t_1}^{t_1+T} f(t) \cos \frac{2\pi n}{T} t dt$$

$$= \frac{2}{T} \int_0^T f(t) \cos n\omega_0 t dt = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos n\omega_0 t dt = \frac{2}{T} \int_{t_1}^{t_1+T} f(t) \cos n\omega_0 t dt$$

= 2 × average value of  $f(\theta) \cos n\theta$  over one cycle of the fundamental.

Values of  $a_1, a_2, a_3$  etc. can be found from above by putting  $n = 1, 2, 3$  etc.

(iii) Similarly, find the value of  $b_n$  by multiplying both sides of Fourier series by  $\sin n\theta$  and integrating it between the limits 0 to  $2\pi$  or 0 to  $T$  or  $-T/2$  to  $T/2$  or  $t_1$  to  $(t_1 + T)$ .

$$\begin{aligned} \therefore b_n &= \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta = 2 \times \frac{1}{2\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta \\ &= \frac{2}{T} \int_0^T f(t) \sin \frac{2\pi n}{T} t dt = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin \frac{2\pi n}{T} t dt = \frac{2}{T} \int_{t_1}^{t_1+T} f(t) \sin \frac{2\pi n}{T} t dt \\ &= \frac{2}{T} \int_0^T f(t) \sin n\omega_0 t dt = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin n\omega_0 t dt = \frac{2}{T} \int_{t_1}^{t_1+T} f(t) \sin n\omega_0 t dt \\ &= 2 \times \text{average value of } f(\theta) \sin n\theta \text{ of } f(t) \sin \frac{2\pi n}{T} t \text{ or } f(t) \sin n\omega_0 t \text{ over one cycle of} \end{aligned}$$

the fundamental.

Values of  $b_1, b_2, b_3$  etc. can be found from above by putting  $n = 1, 2, 3$  etc.

## 21.7. Different Types of Functional Symmetries

A non-sinusoidal wave can have the following types of symmetry:

### 1. Even Symmetry

The function  $f(t)$  is said to possess even symmetry if  $f(t) = f(-t)$ .

It means that as we travel equal amounts in time to the left and right of the origin (*i.e.* along the  $+X$ -axis and  $-X$ -axis), we find the function to have the same value. For example in Fig. 21.2 (a), points  $A$  and  $B$  are equidistant from point  $O$ . Here the two function values are equal and positive. At points  $C$  and  $D$ , the two values of the function are again equal, though negative. Such a function is symmetric with respect to the vertical axis. Examples of even function are:  $t^2$ ,

Fig. 21.2

$\cos 3t, \sin^2 5t (2 + t^2 + t^4)$  and a constant  $A$  because the replacement of  $t$  by  $(-t)$  does not change the value of any of these functions. For example,  $\cos \omega t = \cos(-\omega t)$ .

This type of symmetry can be easily recognised graphically because mirror symmetry exists about the vertical or  $f(t)$  axis. The function shown in Fig. 21.2 has even symmetry because when folded along vertical axis, the portions of the graph of the function for positive and negative time fit exactly, one on top of the other.

The effect of the even symmetry on Fourier series is that the constant  $b_n = 0$  i.e. the wave has no sine terms. In general,  $b_1, b_2, b_3 \dots b_n = 0$ . The Fourier series of an even function contains only a constant term and cosine terms i.e.

$$f(t) = a_0 + \sum_{n=1}^{\infty} a_n \cos n\omega_0 t = a_0 + \sum_{n=1}^{\infty} a_n \cos \frac{2\pi n}{T} t$$

The value of  $a_n$  may be found by integrating over any half-period.

$$\therefore a_n = \frac{2}{\pi} \int_0^{\pi} f(\theta) \cos n\theta d\theta = \frac{4}{T} \int_0^{T/2} f(t) \cos n\omega t dt$$

## 2. Odd Symmetry

A function  $f(t)$  is said to possess odd symmetry if  $f(-t) = -f(t)$ .

It means that as we travel an equal amount in time to the left or right from the origin, we find the function to be the same except for a reversal in sign. For example, in Fig. 21.3 the two points  $A$  and  $B$  are equidistant from point  $O$ . The two function values at  $A$  and  $B$  are equal in magnitude but opposite in sign. In other words, if we replace  $t$  by  $(-t)$ , we obtained the negative of the given function. The  $X$ -axis divides an odd function into two halves with equal areas above and below the  $X$ -axis. Hence,  $a_0 = 0$ .

Examples of odd functions are:  $t, \sin t, t \cos 50t, t(t+t^3+t^5)$  and  $t\sqrt{(1+t^2)}$

A sine function is an odd function because  $\sin(-\omega t) = -\sin \omega t$ .

Fig. 21.3

An odd function has symmetry about the origin rather than about the  $f(t)$  axis which was the case for an even function. The effect of odd symmetry on a Fourier series is that it contains no constant term or cosine term. It means that  $a_0 = 0$  and  $a_n = 0$  i.e.  $a_1, a_2, a_3, \dots, a_n = 0$ . The Fourier series expansion contains only sine terms.

$$\therefore f(t) = \sum_{n=1}^{\infty} b_n \sin n\omega_0 t$$

The value of  $b_n$  may be found by integrating over any half-period.

$$\therefore b_n = \frac{2}{\pi} \int_0^{\pi} f(\theta) \sin n\theta d\theta = \frac{4}{T} \int_0^{T/2} f(t) \sin n\omega t dt$$

### 3. Half-wave Symmetry or Mirror-Symmetry or Rotational Symmetry

A function  $f(t)$  is said to possess half-wave symmetry if  $f(t) = -f(t \pm T/2)$  or  $-f(t) = f(t \pm T/2)$ .

It means that the function remains the same if it is shifted to the left or right by half a period and then flipped over (*i.e.* multiplied by  $-1$ ) in respect to the  $t$ -axis or horizontal axis. It is called mirror symmetry because the negative portion of the wave is the mirror image of the positive portion of the wave displaced horizontally a distance  $T/2$ .

In other words, a waveform possesses half symmetry only when we invert its negative half-cycle and get an exact duplicate of its positive half-cycle. For example, in Fig. 21.4 (a) if we invert the negative half-cycle, we get the dashed  $ABC$  half-cycle which is exact duplicate of the positive half-cycle. Same is the case with the waveforms of Fig. 21.4 (b) and Fig. 21.4 (c). In case

Fig. 21.4

of doubt, it is helpful to shift the inverted half-cycle by a half-period to the left and see if it superimposes the positive half-cycle. If it does so, there exists half-wave symmetry otherwise not. It is seen that the waveform of Fig. 21.4 (d) does not possess half-wave symmetry. It is so because when its negative half-cycle is inverted and shifted by half a period to the left it does not superimpose the positive half-cycle.

It may be noted that half-wave symmetry may be present in a waveform which also shows either odd symmetry or even symmetry:

For example, the square waveform shown in Fig. 21.4 (a) possesses even symmetry whereas the triangular waveform of Fig. 21.4 (b) has odd symmetry. All cosine and sine waves possess half-wave symmetry because

$$\cos \frac{2\pi}{T} \left( t \pm \frac{T}{2} \right) = \cos \left( \frac{2\pi}{T} t \pm \pi \right) = -\cos \frac{2\pi}{T} t; \sin \frac{2\pi}{T} \left( t \pm \frac{T}{2} \right) = \sin \left( \frac{2\pi}{T} t \pm \pi \right) = -\sin \frac{2\pi}{T} t$$

It is worth noting that the Fourier series of any function which possesses half-wave symmetry has zero average value and contains only odd harmonics and is given by

$$f(t) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} \left( a_n \cos \frac{2\pi n}{T} t + b_n \sin \frac{2\pi n}{T} t \right) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} (a_n \cos n\omega_0 t + b_n \sin n\omega_0 t) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} (a_n \cos n\theta + b_n \sin n\theta)$$

$$\text{where, } a_n = \frac{4}{T} \int_0^{T/2} f(t) \cos \frac{2\pi n}{T} t dt = \frac{2}{\pi} \int_0^{\pi} f(\theta) \cos n\theta d\theta \quad \dots n \text{ odd}$$

$$b_n = \frac{4}{T} \int_0^{T/2} f(t) \sin \frac{2\pi n}{T} t dt = \frac{2}{\pi} \int_0^{\pi} f(\theta) \sin n\theta d\theta \quad \dots n \text{ odd}$$

#### 4. Quarter-wave Symmetry

An odd or even function with rotational symmetry is said to possess quarter-wave symmetry.

Fig. 21.5 (a) possesses half-wave symmetry as well as odd symmetry. The wave shown in Fig. 21.5 (b) has both half-wave symmetry and even symmetry.

The mathematical test for quarter-wave symmetry is as under:

$$\text{Odd quarter-wave } f(t) = -f(t + T/2) \text{ and } f(-t) = -f(t)$$

$$\text{Even quarter-wave } f(t) = f(t + T/2) \text{ and } f(t) = f(-t)$$

Fig. 21.5

Since each quarter cycle is the same in a way having quarter-wave symmetry, it is sufficient to integrate over one quarter period *i.e.* from 0 to  $T/4$  and then multiply the result by 4.

(i) If  $f(t)$  or  $f(\theta)$  is odd and has quarter-wave symmetry, then  $a_0$  is 0 and  $a_n$  is 0. Hence, the Fourier series will contain only odd sine terms.

$$\therefore f(t) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} b_n \sin \frac{2\pi n t}{T} \text{ or } f(\theta) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} b_n \sin n\theta, \text{ where } b_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta$$

It may be noted that in the case of odd quarter-wave symmetry, the integration may be carried over a quarter cycle.

$$\therefore a_n = \frac{4}{\pi} \int_0^{\pi/2} f(\theta) \cos n\theta d\theta \quad \dots n \text{ odd}$$

$$= \frac{8}{T} \int_0^{T/4} f(t) \sin n\omega t dt \quad \dots n \text{ odd}$$

(ii) If  $f(t)$  or  $f(\theta)$  is even and, additionally, has quarter-wave symmetry, then  $a_0$  is 0 and  $b_n$  is 0. Hence, the Fourier series will contain only odd cosine terms.

$$\therefore f(\theta) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} a_n \cos n\theta d\theta = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} a_n \cos n\omega_0 t dt; \text{ where } a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta$$

In this case  $a_n$  may be found by integrating over any quarter period.

$$a_n = \frac{4}{\pi} \int_0^{\pi/2} f(\theta) \sin n\theta d\theta \quad \dots n \text{ odd}$$

$$= \frac{8}{T} \int_0^{T/4} f(t) \cos n\omega t dt \quad \dots n \text{ odd}$$

### 21.8. Line or Frequency Spectrum

A plot which shows the amplitude of each frequency component in a complex waveform is called the line spectrum or frequency spectrum (Fig. 21.6). The amplitude of each frequency component is indicated by the length of the vertical line located at the corresponding frequency. Since the spectrum represents frequencies of the harmonics as discrete lines of appropriate height, it is also called a discrete spectrum. The lines decrease rapidly for waves having convergent series. Waves with discontinuities such as the sawtooth and square waves have spectra whose amplitudes decrease slowly because their series have strong high harmonics. On the other hand, the line spectra of waveforms without discontinuities and with a smooth appearance have lines which decrease in height very rapidly.

Fig. 21.6

The harmonic content and the line spectrum of a wave represent the basic nature of that wave and never change irrespective of the method of analysis. Shifting the zero axis changes the symmetry of a given wave and gives its trigonometric series a completely different appearance but the same harmonics always appear in the series and their amplitude remains constant.

Fig. 21.7

Fig. 21.7 shows a smooth wave alongwith its line spectrum. Since there are only sine terms in its trigonometric series (apart from  $a_0 = \pi$ ), the harmonic amplitudes are given by  $b_n$ .

### 21.9. Procedure for Finding the Fourier Series of a Given Function

It is advisable to follow the following steps:

#### 1. Step No. 1

If the function is defined by a set of equations, sketch it approximately and examine for symmetry.

#### 2. Step No. 2

Whatever be the period of the given function, take it as  $2\pi$  (Ex. 20.6) and find the Fourier series in the form

$$f(\theta) = a_0 + a_1 \cos \theta + a_2 \cos 2\theta + \dots + a_n \cos n\theta + b_1 \sin \theta + b_2 \sin 2\theta + \dots + b_n \sin n\theta$$

#### 3. Step No. 3

The value of the constant  $a_0$  can be found in most cases by inspection. Otherwise it can be found as under:

$$a_0 = \frac{1}{2\pi} \int_0^{2\pi} f(\theta) d\theta = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\theta) d\theta$$

#### 4. Step No. 4

If there is no symmetry, then  $a_0$  is found as above whereas the other two Fourier constants can be found by the relation.

$$a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta = \frac{1}{\pi} \int_{-\pi}^{\pi} f(\theta) \cos n\theta d\theta$$

$$b_n = \int_0^{2\pi} f(\theta) \sin n\theta d\theta = \frac{1}{\pi} \int_{-\pi}^{\pi} f(\theta) \sin n\theta d\theta$$

#### 5. Step No. 5

If the function has even symmetry *i.e.*  $f(\theta) = f(-\theta)$ , then  $b_n = 0$  so that the Fourier series will have no sine terms. The series would be given by

$$f(\theta) = a_0 + \sum_{n=1}^{\infty} a_n \cos n\theta \text{ where } a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta = \frac{2}{\pi} \int_0^{\pi} f(\theta) \cos n\theta d\theta$$

#### 6. Step No. 6

If the given function has odd symmetry *i.e.*  $f(-\theta) = -f(\theta)$  then  $a_0 = 0$  and  $a_n = 0$ . Hence, there would be no cosine terms in the Fourier series which accordingly would be given by

$$f(\theta) = \sum_{n=1}^{\infty} b_n \sin n\theta \text{ ; where } b_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta = \frac{2}{\pi} \int_0^{\pi} f(\theta) \sin n\theta d\theta$$

#### 7. Step No. 7

If the function possesses half-wave symmetry *i.e.*  $f(\theta) = -f(\theta \pm \pi)$  or  $f(t) = -f(t \pm T/2)$ , then  $a_0$  is 0 and the Fourier series contains only odd harmonics. The Fourier series is given by

$$f(\theta) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} a_n (\cos n\theta + b_n \sin n\theta)$$

where  $a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta \dots n \text{ odd}$ ,  $b_n = \frac{2}{\pi} \int_0^{\pi} f(\theta) \sin n\theta d\theta \dots n \text{ odd}$

**8. Step No. 8**

If the function has even quarter-wave symmetry then  $a_0 = 0$  and  $b_n = 0$ . It means the Fourier series will contain no sine terms but only odd cosine terms. It would be given by

$$f(\theta) = \sum_{\substack{n=1 \\ \text{odd}}} a_n \cos n\theta ; \text{ where } a_n = \frac{2}{\pi} \int_0^{\pi/2} f(\theta) \cos n\theta d\theta = \frac{4}{\pi} \int_0^{\pi/4} f(\theta) \cos n\theta d\theta \dots n \text{ odd}$$

**9. Step No. 9**

If the function has odd quarter-wave symmetry, then  $a_0 = 0$  and  $a_n = 0$ . The Fourier series will contain only odd sine terms (but no cosine terms).

$$\therefore f(\theta) = \sum_{\substack{n=1 \\ \text{odd}}} b_n \sin n\theta ; \text{ where } b_n = \frac{2}{\pi} \int_0^{\pi/2} f(\theta) \sin n\theta d\theta = \frac{4}{\pi} \int_0^{\pi/4} f(\theta) \sin n\theta d\theta \dots n \text{ odd}$$

**10. Step No. 10**

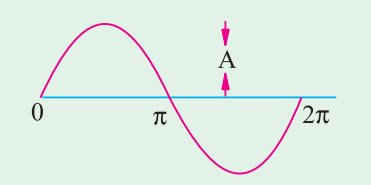

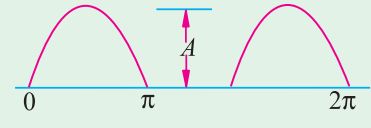

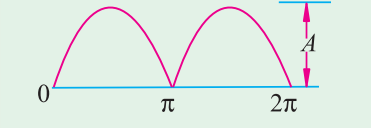

Having found the coefficients, the Fourier series as given in step No. 2 can be written down.

**11. Step No. 11**

The different harmonic amplitudes can be found by combining similar sine and cosine terms

i.e.  $A_n = \sqrt{a_n^2 + b_n^2}$

where  $A_n$  is the amplitude of the  $n_{th}$  harmonic.

Table No. 21.1		
Wave form	Appearance	Equation
A. Sine wave		$f(t) = A = A \sin \omega t$
B. Half-wave rectified sine wave		$f(t) = A \left( \frac{1}{\pi} + \frac{1}{2} \sin \omega t - \frac{2}{3\pi} \cos 2\omega t \right) - \frac{2}{15\pi} \cos 4\omega t - \frac{2}{35\pi} \cos 6\omega t - \frac{2}{63\pi} \cos 8\omega t \dots$
C. Full-wave rectified sine wave		$f(t) = \frac{2A}{\pi} \left( 1 - \frac{2}{3} \cos 2\omega t - \frac{2}{15} \cos 4\omega t - \frac{2}{35} \cos 6\omega t \dots \right)$

**D.** Rectangular or square wave

$$f(t) = \frac{4A}{\pi} \left( \sin \omega t + \frac{1}{3} \sin 3\omega t + \dots \right)$$

$$+ \frac{1}{5} \sin 5\omega t + \frac{1}{7} \sin 7\omega t + \dots$$

$$f(t) = \frac{4A}{\pi} \left( \cos \omega t - \frac{1}{3} \cos 3\omega t + \right.$$

$$\left. \frac{1}{5} \cos 5\omega t + \dots \right)$$

**E.** Rectangular or square wave pulse

$$f(t) = \frac{A}{2} + \frac{2A}{\pi} \left( \sin \omega t + \frac{1}{3} \sin 3\omega t + \right.$$

$$\left. \frac{1}{5} \sin 5\omega t + \frac{1}{7} \sin 7\omega t + \dots \right)$$

**F.** Triangular wave

$$f(t) = \frac{8A}{\pi^2} \left( \sin \omega t - \frac{1}{9} \sin 3\omega t + \frac{1}{25} \right.$$

$$\left. \sin 5\omega t - \frac{1}{49} \sin 7\omega t + \dots \right)$$

$$f(t) = \frac{8A}{\pi^2} \left( \cos \omega t + \frac{1}{9} \cos 3\omega t + \right.$$

$$\left. \frac{1}{25} \cos 5\omega t + \frac{1}{49} \cos 7\omega t + \dots \right)$$

**G.** Triangular pulse

$$f(t) = \frac{A}{2} + \frac{4A}{\pi^2} \left( \sin \omega t - \frac{1}{9} \sin 3\omega t \right.$$

$$\left. + \frac{1}{25} \sin 5\omega t - \frac{1}{49} \sin 7\omega t + \dots \right)$$

**H.** Sawtooth wave

$$f(t) = \frac{2A}{\pi} \left( \sin \omega t - \frac{1}{2} \sin 2\omega t + \right.$$

$$\left. \frac{1}{3} \sin 3\omega t - \frac{1}{4} \sin 4\omega t + \dots \right)$$

**I.** Sawtooth pulse

$$f(t) = \frac{A}{\pi} \left( \frac{\pi}{2} - \sin \omega t - \frac{1}{2} \sin 2\omega t - \frac{1}{3} \sin 3\omega t \right.$$

$$\left. - \frac{1}{4} \sin 4\omega t \right)$$

### 21.10. Wave Analyzer

A wave analyzer is an instrument designed to measure the individual amplitude of each harmonic

Fig. 21.8

component in a complex waveform. It is the simplest form of analysis in the frequency domain and can be performed with a set of tuned filters and a voltmeter. That is why such analyzers are also called frequency-selective voltmeters. Since such analyzers sample the frequency spectrum successively, *i.e.* one after the other, they are called non-real-time analyzers.

The block diagram of a simple wave analyzer is shown in Fig. 21.8. It consists of a tunable fundamental frequency selector that detects the fundamental frequency  $f_1$  which is the lowest frequency contained in the input waveform.

Once tuned to this fundamental frequency, a selective harmonic filter enables switching to multiples of  $f_1$ . After amplification, the output is fed to an a.c. voltmeter, a recorder and a frequency counter. The voltmeter reads the r.m.s amplitude of the harmonic wave, the recorder traces its waveform and the frequency counter gives its frequency. The line spectrum of the harmonic component can be plotted from the above data.

For higher frequencies (MHz) heterodyne wave analyzers are generally used. Here, the input complex wave signal is heterodyned to a higher intermediate frequency (IF) by an internal local oscillator. The output of the IF amplifier is rectified and is applied to a dc voltmeter called heterodyned tuned voltmeter.

Wave analyzer

The block diagram of a wave analyzer using the heterodyning principle is shown in Fig. 21.9.

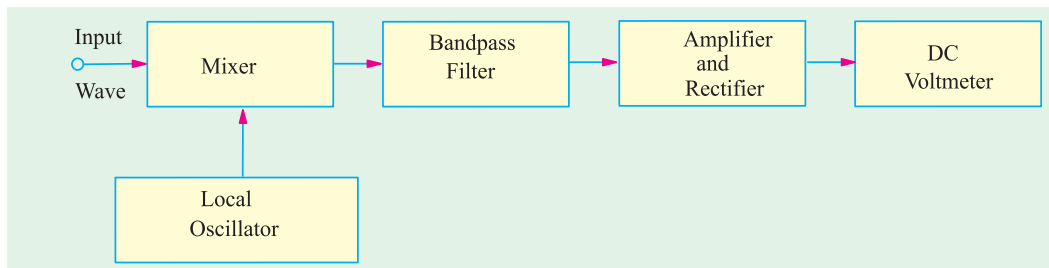

Fig. 21.9

The signal from the internal, variable-frequency oscillator heterodynes with the input signal in a mixer to produce output signal having frequencies equal to the sum and difference of the oscillator frequency  $f_0$  and the input frequency  $f_1$ . Generally, the bandpass filter is tuned to the 'sum frequency' which is allowed to pass through. The signal coming out of the filter is amplified, rectified and then applied to a dc voltmeter having a decibel-calibrated scale. In this way, the peak amplitudes of the fundamental component and other harmonic components can be calculated.

### 21.11. Spectrum Analyzer

It is a real-time instrument *i.e.* it simultaneously displays on a CRT, the harmonic peak

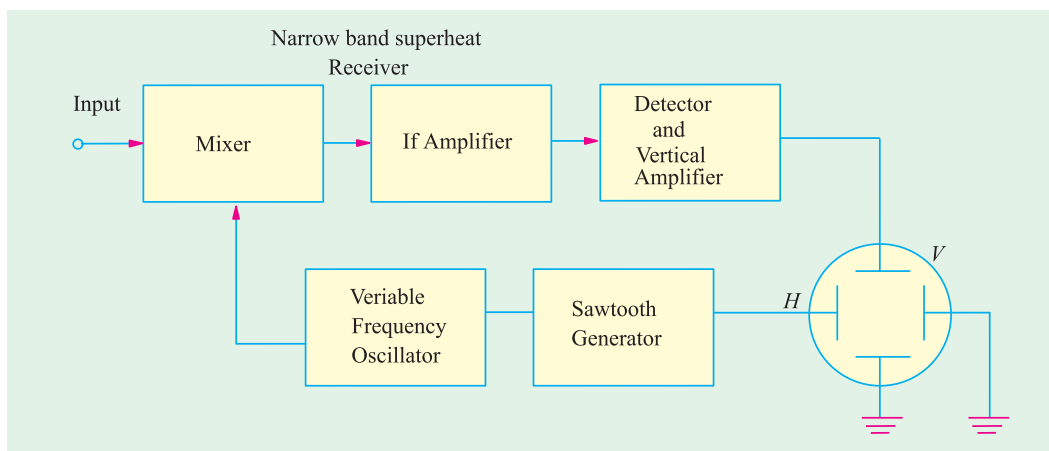

Fig. 21.10

values versus frequency of all wave components in the frequency range of the analyzer. The block diagram of such an analyzer is shown in Fig. 21.10.

As seen, the spectrum analyzer uses a CRT in combination with a narrow-band superheterodyne receiver. The receiver is tuned by varying the frequency of the voltage-tuned variable-frequency oscillator which also controls the sawtooth generator that sweeps the horizontal time base of the CRT deflection plates. As the oscillator is

Spectrum analyzer

swept through its frequency band by the sawtooth generator, the resultant signal mixes and beats with the input signal to produce an intermediate frequency (IF) signal in the mixer. The mixer output occurs only when there is a corresponding harmonic component in the input signal which matches with the sawtooth generator signal. The signals from the IF amplifier are detected and further amplified before applying them to the vertical deflection plates of the CRT. The resultant output displayed on the CRT represents the line spectrum of the input complex or nonsinusoidal waveform.

### 21.12. Fourier Analyzer

A Fourier analyzer uses digital signal processing technique and provides information regarding the contents of a complex wave which goes beyond the capabilities of a spectrum analyzer. These analyzers are based on the calculation of the discrete Fourier transform using an algorithm called the fast Fourier transformer. This algorithm calculates the amplitude and phase of each harmonic component from a set of time domain samples of the input complex wave signal.

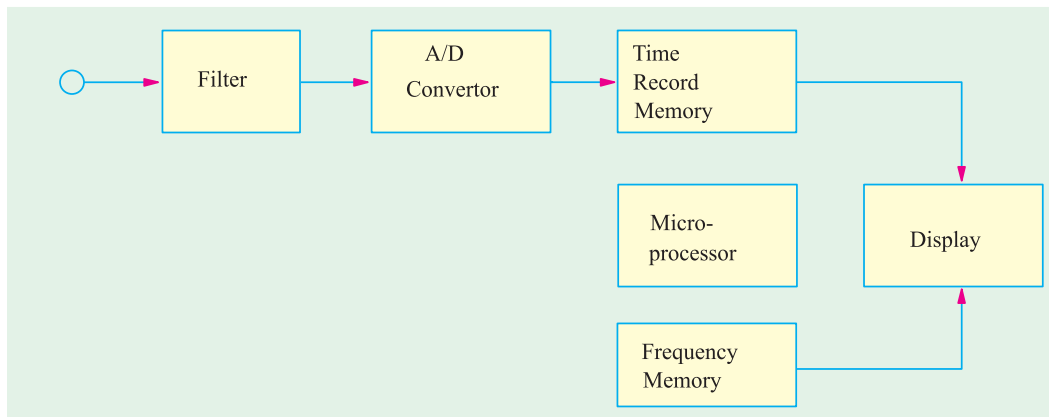

Fig. 21.11

A basic block diagram of a Fourier analyzer is shown in Fig. 21.11. The complex wave signal applied to the instrument is first filtered to remove out-of-band frequency components. Next, the signal is applied to an analog/digital (A/D) convertor which samples and digitizes it at regular time intervals until a full set of samples (called a time record) has been collected. The microprocessor then performs a series of computations on the time data to obtain the frequency-domain results *i.e.* amplitude versus frequency relationships. These results which are stored in memory can be displayed on a CRT or recorded permanently with a recorder or plotter.

Since Fourier analyzers are digital instruments, they can be easily interfaced with a computer or other digital systems. Moreover, as compared to spectrum analyzers, they provide a higher degree of accuracy, stability and repeatability.

Fourier Analyzer

### 21.13. Harmonic Synthesis

It is the process of building up the shape of a complex waveform by adding the instantaneous values of the fundamental and harmonics. It is a graphical procedure based on the knowledge of the different components of a complex waveform.

**Example 21.1.** A complex voltage waveform contains a fundamental voltage of r.m.s. value 220 V and frequency 50 Hz along with a 20% third harmonic which has a phase angle lagging by  $3\pi/4$  radian at  $t = 0$ . Find an expression representing the instantaneous complex voltage  $v$ . Using harmonic synthesis, also sketch the complex waveform over one cycle of the fundamental.

**Solution.** The maximum value of the fundamental voltage is  $= 200 \times \sqrt{2} = 310$  V. Its angular velocity is  $\omega = 2\pi \times 50 = 100\pi$  rad/s. Hence, the fundamental voltage is represented by  $310 \sin 100\pi t$ .

The amplitude of the third harmonic  $= 20\%$  of  $310 = 62$  V. Its frequency is  $3 \times 50 = 150$  Hz. Hence, its angular frequency is  $= 2\pi \times 150 = 300\pi$  rad/s. Accordingly, the third harmonic voltage can be represented by the equation  $62 \sin (300\pi t - 3\pi/4)$ . The equation of the complex voltage is given by  $v = 310 \sin 100\pi t + 62 \sin(300\pi t - 3\pi/4)$ .

Fig 21.12

In Fig. 21.12 are shown one cycle of the fundamental and three cycles of the third harmonic component initially lagging by  $3\pi/4$  radian or  $135^\circ$ . By adding ordinates at different intervals, the complex voltage waveform is built up as shown.

Incidentally, it would be seen that if the negative half-cycle is reversed, it is identical to the positive half-cycle. This is a feature of waveforms possessing half-wave symmetry which contains the fundamental and odd harmonics.

**Example 21.2.** For the nonsinusoidal wave shown in Fig. 21.13, determine (a) Fourier coefficients  $a_0$ ,  $a_3$  and  $b_4$  and (b) frequency of the fourth harmonic if the wave has a period of 0.02 second.

**Solution.** The function  $f(\theta)$  has a constant value from  $\theta = 0$  to  $\theta = 4\pi/3$  radian and 0 value from  $\theta = 4\pi/3$  radian to  $\theta = 2\pi$  radian.

$$(a) a_0 = \frac{1}{2\pi} (\text{net area per cycle})_0^{2\pi} = \frac{1}{2\pi} \left( 6 \times \frac{4\pi}{3} \right) = 4$$

$$a_3 = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos 3\theta d\theta = \frac{1}{\pi} \int_0^{4\pi/3} 6 \cos 3\theta d\theta$$

Fig. 21.13

$$= \frac{6}{\pi} \left| \frac{\sin 3\theta}{3} \right|_0^{4\pi/3} = \frac{2}{\pi} (\sin 4\pi) = 0$$

$$b_4 = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin 4\theta d\theta = \frac{1}{\pi} \int_0^{4\pi/3} 6 \sin 4\theta d\theta$$

$$= \frac{6}{\pi} \left| -\frac{\cos 4\theta}{4} \right|_0^{4\pi/3} = -\frac{3}{2\pi} (\cos 16\pi - \cos 0) = \frac{-3}{2\pi} (-0.5 - 1) = \frac{9}{4\pi}$$

(b) Frequency of the fourth harmonic =  $4f_0 = 4/T = 4/0.02 = 200$  Hz.

**Example 21.3.** Find the Fourier series of the "half sinusoidal" voltage waveform which represents the output of a half-wave rectifier. Sketch its line spectrum.

**Solution.** As seen from Fig. 21.14 (a),  $T = 0.2$  second,  $f_0 = 1/T = 1/0.2 = 5$  Hz and  $\omega_0 = 2\pi f_0 = 10\pi$  rad/s. Moreover, the function has even symmetry. Hence, the Fourier series will contain no sine terms because  $b_n = 0$ .

The limits of integration would not be taken from  $t = 0$  to  $t = 0.2$  second, but from  $t = -0.5$  to  $t = 0.15$  second in order to get fewer equations and hence fewer integrals. The function can be written as

$$f(t) = V_m \cos 10\pi t \quad -0.05 < t < 0.05$$

$$= 0 \quad 0.05 < t < 0.15$$

$$a_0 = \frac{1}{T} \int_{-0.05}^{0.15} f(t) dt = \frac{1}{0.2} \left[ \int_{-0.05}^{0.05} V_m \cos 10\pi t dt + \int_{0.05}^{0.15} 0 dt \right]$$

$$= \frac{V_m}{0.2} \left| \frac{\sin 10\pi t}{10\pi} \right|_{-0.05}^{0.05} = \frac{V_m}{\pi} a_n = \frac{2V_m}{0.2} \int_{-0.05}^{0.05} \cos 10\pi t \cdot \cos 10\pi n t dt$$

The expression we obtain after integration cannot be solved when  $n = 1$  although it can be solved when  $n$  is other than unity. For  $n = 1$ , we have

$$a_1 = 10V_m \int_{-0.05}^{0.05} \cos^2 10\pi t dt = \frac{V_m}{2}$$

$$\text{When } n \neq 1, \text{ then } a_n = 10V_m \int_{-0.05}^{0.05} \cos 10\pi t \cdot \cos 10\pi n t dt$$

$$= \frac{10V_m}{2} \int_{-0.05}^{0.05} [\cos 10\pi(1+n)t \cos 10\pi(1-n)t] dt = \frac{2V_m}{\pi} \cdot \frac{\cos(\pi n/2)}{(1-n^2)} \dots n \neq 1$$

$$a_2 = \frac{2V_m}{\pi} \cdot \frac{\cos \pi}{1-4} = \frac{2V_m}{\pi} \cdot \frac{-1}{-3} = \frac{2V_m}{2\pi}; a_3 = \frac{2V_m}{\pi} \cdot \frac{\cos 3\pi/2}{1-3^2} = 0; a_4 = \frac{2V_m}{\pi} \cdot \frac{\cos 2\pi}{1-4^2} = -\frac{2V_m}{15\pi}$$

$$a_5 = 0; a_6 = \frac{2V_m}{\pi} \cdot \frac{\cos 3\pi}{1-6^2} = \frac{2V_m}{35\pi} \text{ and so on}$$

Substituting the values of  $a_0, a_1, a_2, a_4$  etc. in the standard Fourier series expression given in Art. 20.3. we have

$$f(t) = a_0 + a_1 \cos 2\pi t + a_2 \cos 4\pi t + a_4 \cos 8\pi t + a_6 \cos 12\pi t + \dots$$

Fig. 21.14

$$\begin{aligned}
 &= \frac{V_m}{\pi} + \frac{V_m}{2} \cos 10\pi t + \frac{2V_m}{3\pi} \cos 20\pi t - \frac{2V_m}{15\pi} \cos 40\pi t + \frac{2V_m}{35} \cos 60\pi t \dots \\
 &= V_m \left( \frac{1}{\pi} + \frac{1}{2} \cos \omega_0 t + \frac{2}{3\pi} \cos 2\omega_0 t - \frac{2}{15\pi} \cos 4\omega_0 t + \frac{2}{35\pi} \cos 6\omega_0 t \dots \right)
 \end{aligned}$$

The line spectrum which is a plot of the harmonic amplitudes versus frequency is given in Fig. 21.14(b).

**Example 21.4.** Determine the Fourier series for the square voltage pulse shown in Fig. 21.15 (a) and plot its line spectrum. (Network Theory, Nagpur Univ. 1992)

**Solution.** The wave represents a periodic function of  $\theta$  or  $\omega t$  or  $\left(\frac{2\pi t}{T}\right)$  having a period extending over  $2\pi$  radians or  $T$  seconds. The general expression for this wave can be written as

$$\begin{aligned}
 f(\theta) &= a_0 + a_1 \cos \theta + a_2 \cos 2\theta + a_3 \cos 3\theta + \dots \\
 &\dots + b_1 \sin \theta + b_2 \sin 2\theta + b_3 \sin 3\theta + \dots
 \end{aligned}$$

Fig. 21.15

(i) Now,  $f(\theta) = V$ ;  $\theta = 0$  to  $\theta = \pi$ ;  $f(\theta) = 0$ , from  $\theta = \pi$  to  $\theta = 2\pi$

$$\therefore a_0 = \frac{1}{2\pi} \int_0^{2\pi} f(\theta) d\theta = \frac{1}{2\pi} \left\{ \int_0^{\pi} f(\theta) d\theta + \int_{\pi}^{2\pi} f(\theta) d\theta \right\}$$

$$\text{or } a_0 = \frac{1}{2\pi} \left\{ \int_0^\pi V d\theta + \int_\pi^{2\pi} 0 d\theta \right\} = \frac{V}{2\pi} [\theta]_0^\pi + 0 = V_{2\pi} \times \pi = \frac{V}{2}$$

$$\begin{aligned} \text{(ii) } a_n &= \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta = \frac{1}{\pi} \left\{ \int_0^\pi V \cos n\theta d\theta + \int_\pi^{2\pi} 0 \times \cos n\theta d\theta \right\} \\ &= \frac{V}{\pi} \int_0^\pi \cos n\theta d\theta + 0 = \frac{V}{n\pi} [\sin n\theta]_0^\pi = 0 \quad \dots \text{ whether } n \text{ is odd or even} \end{aligned}$$

$$\begin{aligned} \text{(iii) } b_n &= \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta = \frac{1}{\pi} \left\{ \int_0^\pi V \sin n\theta d\theta + \int_\pi^{2\pi} 0 \times \sin n\theta d\theta \right\} \\ &= \frac{V}{\pi} \int_0^\pi \sin n\theta d\theta + 0 = \frac{V}{\pi} \left[ \frac{-\cos n\theta}{n} \right]_0^\pi = \frac{V}{n\pi} (-\cos n\pi + 1) \end{aligned}$$

Now, when  $n$  is odd,  $(1 - \cos n\pi) = 2$  but when  $n$  is even,  $(1 - \cos n\pi) = 0$ .

$$\therefore b_1 = \frac{2V}{\pi} \dots n = 1; b_2 = \frac{V}{2\pi} \times 0 = 0 \dots n = 2; b_3 = \frac{V}{3\pi} \times 2 = \frac{2V}{3\pi} \dots n = 3 \text{ and so on.}$$

Hence, substituting the values of  $a_0, a_1, a_2$  etc. and  $b_1, b_2$  etc. in the above given Fourier series, we get

$$f(\theta) = \frac{V}{2} + \frac{2V}{\pi} \sin \theta + \frac{2V}{3\pi} \sin 3\theta + \frac{2V}{5\pi} \sin 5\theta + \dots = \frac{E}{2} + \frac{2V}{\pi} \left( \sin \omega_0 t + \frac{1}{3} \sin 3\omega_0 t + \frac{1}{5} \sin 5\omega_0 t + \dots \right)$$

It is seen that the Fourier series contains a constant term  $V/2$  and odd harmonic components whose amplitudes are as under:

$$\text{Amplitude of fundamental or first harmonic} = \frac{2V}{\pi}$$

$$\text{Amplitude of second harmonic} = \frac{2V}{3\pi}$$

$$\text{Amplitude of third harmonic} = \frac{2V}{5\pi} \text{ and so on.}$$

The plot of harmonic amplitude versus the harmonic frequencies (called line spectrum) is shown in Fig. 21.15 (b).

**Example 21.5.** Obtain the Fourier series for the square wave pulse train indicated in Fig. 21.16. **(Network Theory and Design, AMIETE June, 1990)**

**Solution.** Here  $T = 2$  second,  $\omega_0 = 2\pi/T = \pi$  rad/s. The given function is defined by

$$\begin{aligned} f(t) &= 1 \quad 0 < t < 1 = 0 \text{ and} \\ &= 0; \quad 1 < t < 2 \end{aligned}$$

$$a_0 = \frac{1}{T} \int_0^T f(t) dt = \frac{1}{2} \int_0^2 1 dt = \frac{1}{2} \left[ \int_0^1 1 dt + \int_1^2 0 dt \right] = \frac{1}{2}$$

Even otherwise by inspection  $a_0 = (1 + 0)/2 = 1/2$

$$a_n = \frac{2}{T} \int_0^T f(t) \cos n\omega_0 t dt = \frac{2}{2} \int_0^2 1 \cos n\pi t dt = \left[ \int_0^1 1 \cos n\pi t dt + \int_1^2 (0) \cos n\pi t dt \right]$$

$$= \int_0^1 \cos n\pi t dt = \left| \frac{\sin n\pi t}{n\pi} \right|_0^1 = 0$$

$$b_n = \frac{2}{T} \int_0^T f(t) \sin n\omega_0 t dt = \left[ \int_0^1 1 \cdot \sin n\pi t dt \right] + \int_1^2 (0) \sin n\pi t dt = \int_0^1 \sin n\pi t dt$$

$$= \left| \frac{-\cos n\pi t}{n\pi} \right|_0^1 = \frac{1 - \cos n\pi}{n\pi}$$

$$\therefore b_n = 2/n\pi \dots \text{when } n \text{ is odd; } = 0$$

... when  $n$  is even

Fig. 21.16

$$\therefore f(t) = a_0 + \sum_{\substack{n=1 \\ \text{odd}}} \frac{2}{n} \sin 3n t + \frac{1}{2} - \frac{2}{2} \sin t + \frac{1}{3} \sin 3 t - \frac{1}{5} \sin 5 t, \text{ etc.}$$

**Example 21.6.** Find the trigonometric Fourier series for the square voltage waveform shown in Fig. 21.17(a) and sketch the line spectrum.

**Solution.** The function shown in Fig. 21.17 (a) is an odd function because at any time  $f(-t) = -f(t)$ . Hence, its Fourier series will contain only sine terms *i.e.*  $a_n = 0$ . The function also possesses half-wave symmetry, hence, it will contain only odd harmonics.

As seen from Art. 21.7 (2) the Fourier series for the above wave is given by

$$f(\theta) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} b_n \sin n\theta \text{ where } b_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta$$

$$= \frac{1}{\pi} \left\{ \int_0^{\pi} V \sin n\theta d\theta + \int_{\pi}^{2\pi} -V \sin n\theta d\theta \right\} = \frac{V}{\pi n} \left| -\cos n\theta \right|_0^{\pi} + \frac{V}{\pi n} \left| \cos n\theta \right|_{\pi}^{2\pi}$$

$$= \frac{V}{\pi n} \{ (-\cos n\pi + \cos 0) - \cos n\pi \}$$

$$= \frac{V}{\pi n} \{ (1 - \cos n\pi) + (1 - \cos n\pi) \} = \frac{2V}{\pi n} (1 - \cos n\pi)$$

Now,  $1 - \cos n\pi = 2$  when  $n$  is odd

and  $b_n = 0$  when  $n$  is even

$$\therefore b_1 = \frac{2V}{\pi} \times 2 = \frac{4V}{\pi} \dots \text{putting } n = 1; b_2 = 0 \dots \text{putting } n = 2$$

$$b_3 = \frac{2V}{\pi \cdot 3} \times 2 = \frac{4V}{3\pi} \dots \text{putting } n = 3; b_4 = 0 \dots \text{putting } n = 4$$

$$b_5 = \frac{2V}{\pi \cdot 5} \times 2 = \frac{4V}{5\pi} \dots \text{putting } n = 5 \text{ and so on.}$$

Fig. 21.17

Hence, the Fourier series for the given waveform is

$$f(\theta) = \frac{4V}{\pi} \sin \theta - \frac{4V}{3\pi} \sin 3\theta + \frac{4V}{5\pi} \sin 5\theta - \dots$$

$$= \frac{4V}{\pi} \left( \sin \omega_0 t + \frac{1}{3} \sin 3\omega_0 t + \frac{1}{5} \sin 5\omega_0 t + \dots \right) = \frac{4V}{\pi} \left( \sin \frac{2\pi}{T} t + \frac{1}{3} \sin \frac{6\pi}{T} t + \frac{1}{5} \sin \frac{10\pi}{T} t + \dots \right)$$

The line spectrum of the function is shown in Fig. 21.17 (b). It would be seen that the harmonic amplitudes decrease as  $1/n$ , that is, the third harmonic amplitude is  $1/3$  as large as the fundamental, the fifth harmonic is  $1/5$  as large and so on.

**Example 21.7.** Determine the Fourier series for the square voltage waveform shown in Fig. 21.17 (a). Plot its line spectrum.

**Solution.** This is the same question as given in Ex. 21.6 but has been repeated to illustrate a slightly different technique. As seen from Fig. 21.17(a)  $T = 2\pi$ , hence,  $\omega_0 = 2\pi f_0 = 2\pi / T = 2\pi / 2\pi = 1$ . Over one period the function can be defined as

$$f(t) = V \quad 0 < t < \pi$$

$$= -V, \quad \pi < t < 2\pi$$

$$b_n = \frac{1}{\pi} \int_0^\pi V \sin n t dt - \frac{1}{\pi} \int_\pi^{2\pi} V \sin n t dt = \frac{1}{\pi} \int_0^\pi V \sin n t dt - \frac{1}{\pi} \int_0^\pi V \sin n t dt$$

$$= \frac{1}{\pi} \int_0^\pi V \sin n t dt + \frac{1}{\pi} \int_\pi^{2\pi} (-V) \sin n t dt = \frac{V}{\pi} \left[ -\frac{\cos n t}{n} \right]_0^\pi + \frac{V}{\pi} \left[ \frac{\cos n t}{n} \right]_\pi^{2\pi}$$

$$= -\frac{V}{n\pi}(\cos n\pi - \cos 0) + \frac{V}{n\pi}(\cos 2n\pi - \cos n\pi)$$

Since  $\cos 0$  is 1 and  $\cos 2n\pi = 1 \therefore b_n = \frac{2V}{n\pi}(1 - \cos n\pi)$

When  $n$  is even,  $\cos n\pi = 1 \therefore b_n = 0$

When  $n$  is odd,  $\cos n\pi = -1 \therefore b_n = \frac{2V}{n}(1 - (-1)) = \frac{4V}{n}, n = 1, 3, 5, \dots$

Substituting the value of  $b_n$ , the Fourier series become

$$f(t) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} \frac{4V}{n\pi} \sin nt = \frac{4V}{\pi} \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} \frac{1}{n} \sin nt = \frac{4V}{\pi} \left( \sin t + \frac{1}{3} \sin 3t + \frac{1}{5} \sin 5t + \dots \right)$$

Since  $\omega_0 = 1$ , the above expression in general terms becomes

$$f(t) = \frac{4V}{\pi} \left( \sin \omega_0 t + \frac{1}{3} \sin 3\omega_0 t + \frac{1}{5} \sin 5\omega_0 t + \dots \right)$$

The line spectrum is as shown in Fig. 21.17 (b).

**Example 21.8.** Determine the Fourier series of the square voltage waveform shown in Fig. 21.18.

**Solution.** As compared to Fig. 21.17 (a) given above, the vertical axis of figure has been shifted by  $\pi/2$  radians. Replacing  $t$  by  $(t + \pi/2)$  in the above equation, the Fourier series of the waveform shown in Fig. 21.18 becomes

$$\begin{aligned} f(t) &= \frac{4V}{\pi} \left[ \sin \left( t + \frac{\pi}{2} \right) + \frac{1}{3} \sin 3 \left( t + \frac{\pi}{2} \right) + \frac{1}{5} \sin 5 \left( t + \frac{\pi}{2} \right) + \dots \right] \\ &= \frac{4V}{\pi} \left( \cos t - \frac{1}{3} \cos 3t + \frac{1}{5} \cos 5t \dots \right) \end{aligned}$$

Fig. 21.18

**Example 21.9.** Determine the trigonometric Fourier series for the half-wave rectified sine wave form shown in Fig. 21.19 (a) and sketches line spectrum.

Fig. 21.19

**Solution.** The given waveform shows no symmetry, hence its series would contain both sine and cosine terms. Moreover, its average value is not obtainable by inspection, hence it will have to be found by integration.

Here,  $T = 2\pi$ . Hence, equation of the given waveform is  $V = V_m \sin \omega t = V_m \sin t$ .

The given waveform is defined by  $f(t) = V_m \sin t, 0 < t < \pi = 0, \pi < t < 2\pi$

$$\begin{aligned} a_0 &= \frac{1}{2\pi} \int_0^{2\pi} f(t) dt = \frac{1}{2\pi} \left[ \int_0^{\pi} V_m \sin t dt + \int_{\pi}^{2\pi} 0 dt \right] \\ &= \frac{V_m}{2\pi} [-\cos t]_0^{\pi} = -\frac{V_m}{2\pi} (\cos \pi - \cos 0) = \frac{V_m}{\pi} \\ a_n &= \frac{1}{\pi} \int_0^{\pi} f(t) \cos nt dt = \frac{1}{\pi} \int_0^{\pi} V_m \sin t \cos nt dt \\ &= \frac{V_m}{2\pi} \int_0^{\pi} [\sin(n+1)t - \sin(n-1)t] dt = \frac{V_m}{2\pi} \left[ \frac{-\cos(n+1)t}{n+1} + \frac{\cos(n-1)t}{n-1} \right]_0^{\pi} \\ &= \frac{V_m}{2\pi} \left[ -\frac{\cos(n+1)\pi}{n+1} + \frac{\cos(n-1)\pi}{n-1} + \frac{1}{n+1} - \frac{1}{n-1} \right] \end{aligned}$$

when  $n$  is even,  $\cos(n+1)\pi = -1$  and  $\cos(n-1)\pi = -1$

$$\therefore a_n = \frac{V_m}{2\pi} \left[ \frac{1}{n+1} - \frac{1}{n-1} + \frac{1}{n+1} - \frac{1}{n-1} \right] = -\frac{2V_m}{\pi(n^2-1)} \quad \dots n = 2, 4, 6 \text{ etc.}$$

when  $n$  is odd and  $\neq 1$ ,  $\cos(n+1)\pi = 1$  and  $\cos(n-1)\pi = 1$

$$\therefore a_n = \frac{V_m}{2\pi} \left( -\frac{1}{n+1} + \frac{1}{n-1} + \frac{1}{n+1} - \frac{1}{n-1} \right) = 0 \quad \dots n = 3, 5, 7 \text{ etc.}$$

$$\text{when } n = 1, a_1 = \frac{1}{\pi} \int_0^{\pi} V_m \sin t \cos t dt = \frac{V_m}{2\pi} \int_0^{\pi} \sin 2t dt = 0$$

Hence,  $a_n = 0 \quad \dots n = 1, 3, 5 \dots$

$$\begin{aligned} b_n &= \frac{1}{\pi} \int_0^{2\pi} f(t) \sin nt dt = \frac{1}{\pi} \left[ \int_0^{\pi} V_m \sin t \sin nt dt + \int_{\pi}^{2\pi} (0) \sin nt dt \right] \\ &= \frac{V_m}{\pi} \int_0^{\pi} \sin t \sin nt dt = 0 \text{ for } n = 2, 3, 4, 5 \text{ etc.} \end{aligned}$$

However, the expression indeterminate for  $n = 1$  so that  $b_1$  has to be evaluated separately.

$$b_1 = \frac{1}{\pi} \int_0^{\pi} V_m \sin t \cdot \sin t dt = \frac{V_m}{\pi} \int_0^{\pi} \sin^2 t dt = \frac{V_m}{2}$$

The required Fourier series for the half-wave rectified voltage waveform is

$$\begin{aligned} f(t) &= \frac{V_m}{\pi} + \frac{V_m}{2} \sin t - \frac{2V_m}{\pi} \sum_{\substack{n=1 \\ \text{even}}}^{\infty} \left( \frac{\cos nt}{n^2-1} \right) \\ &= \frac{V_m}{\pi} \left( 1 + \frac{\pi}{2} \sin t - \frac{2}{3} \cos 2t - \frac{2}{15} \cos 4t - \frac{2}{35} \cos 6t \dots \right) \end{aligned}$$

$$\begin{aligned}
 &= \frac{V_m}{\pi} \left( 1 + \frac{\pi}{2} \sin \omega_0 t - \frac{2}{3} \cos 2\omega_0 t - \frac{2}{15} \cos 4\omega_0 t - \frac{2}{35} \cos 6\omega_0 t - \dots \right) \\
 &= \frac{V_m}{T} \left( 1 + \frac{\pi}{2} \sin \theta - \frac{2}{3} \cos 2\theta - \frac{2}{15} \cos 4\theta - \frac{2}{35} \cos 6\theta - \dots \right)
 \end{aligned}$$

The line spectrum is shown in Fig. 21.19 (b) which has a strong fundamental term with rapidly decreasing amplitudes of the higher harmonics.

**Example 21.10.** Find the trigonometrical Fourier series for the full wave rectified voltage sine wave shown in Fig. 21.20.

**Solution.** Since the given function has even symmetry,  $b_n = 0$  i.e. it will contain no sine terms in its series.

The equation of the sinusoidal sine wave given by  $V = V_m \sin \theta$ . In other words,  $f(\theta) = V_m \sin \theta$ .

$$a_0 = \frac{1}{2\pi} \int_0^{2\pi} f(\theta) d\theta = \frac{1}{2\pi} \int_0^{2\pi} V_m \sin \theta d\theta = \frac{2V_m}{2\pi} \int_0^{\pi} \sin \theta d\theta$$

It is so because the two parts  $0 - \pi$  and  $\pi - 2\pi$  are identical.

$$\therefore a_0 = \frac{V_m}{\pi} \left[ -\cos \theta \right]_0^{\pi} = \frac{2V_m}{\pi}$$

$$a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta = \frac{2V_m}{\pi} \int_0^{\pi} \sin \theta \cos n\theta d\theta$$

$$\text{Now, } \sin A \cos B = \frac{1}{2} [\sin(A+B) + \sin(A-B)]$$

$$\therefore a_n = \frac{2V_m}{\pi} \int_0^{\pi} [\sin(1+n)\theta + \sin(1-n)\theta] d\theta$$

Fig. 21.20

$$= -\frac{V_m}{\pi} \frac{\cos(1+n)\theta}{(1+n)} + \frac{\cos(1-n)\theta}{(1-n)}$$

$$= 0 = \frac{-V_m}{\pi} \left[ \frac{\cos(1+n)\pi}{1+n} + \frac{\cos(1-n)\pi}{1-n} - \frac{1}{1+n} - \frac{1}{1-n} \right] \dots \text{ when } n \text{ is odd}$$

However, when  $n$  is even, then

$$a_n = \frac{V_m}{1} \frac{1}{n} \frac{1}{1} \frac{1}{n} \frac{1}{1} \frac{1}{n} \frac{1}{1} \frac{1}{n} \frac{2V_m}{1} \frac{1}{n} \frac{1}{1} \frac{1}{n} \frac{4V_m}{(n^2-1)}$$

$$\therefore f(\theta) = a_0 - \frac{4V_m}{\pi} \sum_{\substack{n=2 \\ \text{even}}}^{\infty} \frac{\cos 2n\theta}{(n^2-1)}$$

$$\therefore f(\theta) = \frac{2V_m}{\pi} - \frac{4V_m}{\pi} \left( \frac{1}{3} \cos^2 \theta - \frac{1}{15} \cos 4\theta + \frac{1}{35} \cos 6\theta + \dots \right)$$

**Example 21.11.** Determine the Fourier series for the waveform shown in Fig. 21.21 (a) and sketch its line spectrum.

**Solution.** It is seen from Fig. 21.21 (a) that the waveform equation is  $f(\theta) = (V_m / \pi)\theta$ . The given function  $f(\theta)$  is defined by

$$f(\theta) = \begin{cases} \frac{V_m}{\pi} \theta, & 0 \leq \theta < \pi \\ 0, & \pi \leq \theta < 2\pi \end{cases}$$

Since the function possesses neither even nor odd symmetry, it will contain both sine and cosine terms.

Average value of the wave over one cycle is  $V_m/4$  or  $a_0 = V_m/4$ . It is so because the average value over the first half cycle is  $V_m/2$  and over the second half cycle is 0 hence, the average value

$$\text{for full cycle is } = \frac{(V_m/2) + 0}{2} = \frac{V_m}{4}$$

$$a_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \cos n\theta d\theta = \frac{1}{\pi} \left[ \int_0^{\pi} (V_m/\pi)\theta \cos n\theta d\theta + \int_{\pi}^{2\pi} (0) \cos n\theta d\theta \right]$$

$$= \frac{V_m}{\pi^2} \int_0^{\pi} \theta \cos n\theta d\theta = \frac{V_m}{\pi^2} \left[ \frac{\cos n\theta}{n^2} + \frac{\theta}{n} \sin n\theta \right]_0^{\pi} = \frac{V_m}{\pi^2 n^2} (\cos n\pi - 1)$$

$$\therefore a_n = 0 \text{ when } n \text{ is odd because } \cos n\pi - 1 = 0$$

$$= -2V_m / \pi^2 n^2 \text{ when } n \text{ is even}$$

$$b_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta d\theta = \frac{1}{\pi} \int_0^{\pi} (V_m/\pi)\theta \sin n\theta d\theta + \int_{\pi}^{2\pi} (0) \sin n\theta d\theta$$

$$= \frac{1}{\pi} \int_0^{\pi} \left( \frac{V_m}{\pi} \right) \theta \sin n\theta d\theta = \frac{V_m}{\pi^2} \left[ \frac{\sin n\theta}{n^2} - \frac{\theta}{n} \cos n\theta \right]_0^{\pi} = \frac{-V_m}{\pi n} \cos n\pi$$

$$\therefore b_n = -V_m / \pi n \text{ when } n \text{ is even } b_n = +V_m / \pi n \text{ when } n \text{ is odd}$$

Substituting the values of various constants in the general expression for Fourier series, we get

$$f(\theta) = \frac{V_m}{4} - \frac{2V_m}{\pi^2} \cos \theta - \frac{2V_m}{(3\pi)^2} \cos 3\theta - \frac{2V_m}{(5\pi)^2} \cos 5\theta \dots$$

$$+ \frac{V_m}{\pi} \sin \theta - \frac{V_m}{2\pi} \sin 2\theta + \frac{V_m}{3\pi} \sin 3\theta \dots$$

Fig. 21.21

The amplitudes of even harmonics are given directly by  $b_n$  but amplitudes of odd harmonics are given by  $A_n = \sqrt{a_n^2 + b_n^2}$  (Art. 21.4)

For example,

$$A_1 = \sqrt{(2V_m / \pi^2)^2 + (V_m / \pi)^2} = 0.377 V_m$$

$$A_3 = \sqrt{\left(\frac{2V_m}{(3\pi)^2}\right)^2 + \left(\frac{V_m}{2\pi}\right)^2} = 0.109 V_m$$

$$A_5 = \sqrt{\left(\frac{2V_m}{(5\pi)^2}\right)^2 + \left(\frac{V_m}{5\pi}\right)^2} = 0.064 V_m \text{ and so on.}$$

The line spectrum is as shown in Fig. 21.21 (b).

**Example 21.12.** Find the Fourier series for the sawtooth waveform shown in Fig. 21.22 (a). Sketch its line spectrum.

**Solution.** Using by the relation  $y = mx$ , the equation of the function becomes  $f(t) = 1, t$  or  $f(t) = t$ .

$$T = 2, \omega_0 = 2\pi / T = 2\pi / 2 = \pi$$

$$\text{By inspection it is clear that } a_0 = 2/2 = 1, a_n = \frac{2}{T} \int_0^T f(t) \cos n\omega_0 t = \int_0^2 t \cdot \cos n\pi t \cdot dt$$

Since we have to find the integral of two functions, we use the technique of integration by parts *i.e.*

$$\int u v dx = u \int v dx - \int \left( \frac{du}{dx} \int v dx \right) dx$$

$$\begin{aligned} \therefore a_n &= t \int_0^2 \cos n\pi t dt - \int_0^2 \left( 1 \int_0^2 \cos n\pi t dt \right) dt \\ &= \left[ \frac{t \sin n\pi t}{n\pi} \right]_0^2 + \left[ \frac{\cos n\pi t}{(n\pi)^2} \right]_0^2 = 0 + \frac{1}{(n\pi)^2} (\cos 2n\pi - \cos 0) \end{aligned}$$

Since  $\cos 2n\pi = \cos 0$  for all values of  $n$ , hence  $a_n = 0$

Fig. 21.22

$$b_n = \frac{2}{T} \int_0^T f(t) \sin n\omega_0 t dt = \int_0^2 t \sin n\pi t dt$$

Employing integration by parts, we get,

$$\begin{aligned} b_n &= t \int_0^2 \sin n\pi t dt - \int_0^2 \left( 1 \int_0^2 \sin n\pi t dt \right) dt \\ &= \left[ t \cdot \frac{-\cos n\pi t}{n\pi} \right]_0^2 - \int_0^2 \frac{-\cos n\pi t}{n\pi} dt = \left[ \frac{-t \cos n\pi t}{n\pi} \right]_0^2 + \left[ \frac{\sin n\pi t}{(n\pi)^2} \right]_0^2 = \frac{\sin 2n\pi}{(n\pi)^2} - \frac{2}{n\pi} \cos 2n\pi \end{aligned}$$

The sine term is 0 for all values of  $n$  because sign of any multiple of  $2\pi$  is 0. Since value of cosine term is 1 for any multiple of  $2\pi$ , we have,  $b_n = -2/n\pi$ .

$$\begin{aligned} \therefore f(t) &= a_0 + \sum_{n=1}^{\infty} b_n \sin n\omega_0 t = a_0 - \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \sin n\pi t \\ &= 1 - \frac{2}{\pi} \left( \sin \pi t + \frac{1}{2} \sin 2\pi t + \frac{1}{3} \sin 3\pi t + \dots \right) \end{aligned}$$

The line spectrum showing the amplitudes of various harmonics is shown in Fig. 21.22 (b).

**Example 21.13.** Determine the trigonometric Fourier series of the triangular waveform shown in Fig. 21.23.

**Solution.** Since the waveform possesses odd symmetry, hence  $a_0 = 0$  and  $a_n = 0$  i.e. there would be  $n_o$  cosine terms in the series. Moreover, the waveform has half-wave symmetry. Hence, series will have only odd harmonics. In the present case, there would be only odd sine terms. Since the waveform possesses quarter-wave symmetry, it is necessary to integrate over only one quarter period of finding the Fourier coefficients.

Fig. 21.23

$$f(t) = \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} b_n \sin n\omega_0 t$$

$$\text{where } b_n = \frac{8}{T} \int_0^{T/4} f(t) \sin n\omega_0 t$$

The quarter-wave of the given waveform can be represented by equation of a straight line. Slope of the straight line is  $V_m / (T/4) = 4V_m / T$ .

Hence, using  $Y = mx$ , we have

$$f(t) = \left( \frac{4V_m}{T} \right) t \quad 0 < t < T/4 \quad \therefore b_n = \frac{8}{T} \int_0^{T/4} \left( \frac{4V_m}{T} \right) t \sin n\omega_0 t = \frac{32V_m}{T^2} \int_0^{T/4} t \sin n\omega_0 t$$

Using the theorem of integration by parts, we have

$$b_n = \frac{32V_m}{T^2} \left[ t \int_0^{T/4} \sin n\omega_0 t \, dt - \int_0^{T/4} \left( 1 \cdot \int_0^{T/4} \sin n\omega_0 t \, dt \right) dt \right]$$

$$\frac{32V_m}{T^2} \left[ \frac{t}{4} \frac{\cos n\omega_0 T/4}{n\omega_0} - \left| \frac{\sin n\omega_0 t}{(n\omega_0)^2} \right|^{T/4} - \frac{32V_m}{T^2} \left[ \frac{T}{4} \frac{\cos n\omega_0 T/4}{n\omega_0} - \frac{\sin n\omega_0 T/4}{(n\omega_0)^2} \right] \right]$$

$$\text{Now, } \omega_0 = 2\pi/T \text{ or } \omega_0 T = 2\pi \quad \therefore n\omega_0 T/4 = n\pi/2$$

$$\therefore \cos n\omega_0 T/4 = \cos n\pi/2 = 0 \text{ when } n \text{ is odd}$$

$$\therefore b_n = \frac{32V_m}{n^2 \omega_0^2 T^2} \sin n\omega_0 \frac{T}{4} = \frac{32V_m}{n^2 (2\pi)^2} \sin \frac{n\pi}{2} = \frac{8V_m}{n^2 \pi^2} \sin \frac{n\pi}{2}$$

$$\therefore b_n = \frac{8V_m}{n^2 \pi^2} \dots n = 1, 5, 9, 13 \dots \quad b_n = \frac{-8V_m}{n^2 \pi^2} \dots n = 3, 7, 11, 15, \dots$$

Substituting this value of  $b_n$ , the Fourier series for the given waveform becomes

$$f(t) = \frac{8V_m}{2} \sin \omega_0 t - \frac{1}{3^2} \frac{8V_m}{2} \sin 3\omega_0 t + \frac{1}{5^2} \frac{8V_m}{2} \sin 5\omega_0 t - \frac{1}{7^2} \frac{8V_m}{2} \sin 7\omega_0 t \dots$$

**Example 21.14.** Determine the Fourier series of the triangular waveform shown in Fig. 21.24.

**Solution.** Since the function has even symmetry,  $b_n = 0$ . Moreover, it also has half-wave symmetry, hence,  $a_0 = 0$ . The Fourier series

can be written as  $f(t) = \sum_{n=1}^{\infty} a_n \cos n\omega_0 t$  where

$$a_n = \frac{2}{T} \int_0^{T/2} f(t) \cos n \omega_0 t dt.$$

Fig. 21.24

The function is given by the relation  $f(t) = \frac{4V_m}{T} t - \frac{T}{4}$

It is so because for the interval  $0 \leq t \leq T/2$ , the slope of the line is  $4V_m/T$ .

$$\therefore a_n = \frac{2}{T} \int_0^{T/2} f(t) \cos n \omega_0 t dt = \frac{4}{T} \int_0^{T/4} f(t) \cos n \omega_0 t dt$$

$$= \frac{16V_m}{T^2} \int_0^{T/2} t \cos n \omega_0 t dt = \frac{16V_m}{T^2} \int_0^{T/2} t \cos n \omega_0 t dt = \frac{4V_m}{T} \int_0^{T/2} \cos n \omega_0 t dt$$

$$= \frac{-16V_m}{T^2} \left[ \frac{1}{4n^2\omega_0^2} \cdot \cos n\omega_0 t + \frac{t}{n\omega_0} \sin n\omega_0 t \right]_0^{T/2} + \frac{4V_m}{T} \left[ \frac{\sin n\omega_0 t}{n\omega_0} \right]_0^{T/2}$$

Substituting  $\omega = 2\pi/T$ , we get

$$a_n = \frac{16V_m}{T^2} \frac{T^2}{4n^2} (\cos n\pi - 1) - \frac{T^2}{4n} (\sin n\pi) - \frac{2V_m}{n} \sin n\pi$$

Now,  $\sin n\pi = 0$  for all values of  $n$ ,  $\cos n\pi = 1$  when  $n$  is even and  $-1$  when  $n$  is odd.

$$\therefore a_n = \frac{8V_m}{\pi^2 n^2}$$

$$\therefore f(t) = \sum_{\substack{n=0 \\ \text{odd}}}^{\infty} \frac{8V_m}{\pi^2 n^2} \cos n\omega_0 t = \frac{8V_m}{\pi^2} \sum_{\substack{n=1 \\ \text{odd}}}^{\infty} \frac{\cos n\omega_0 t}{n^2}$$

$$= \frac{8V_m}{2} \cos \omega_0 t - \frac{1}{9} \cos 3 \omega_0 t + \frac{1}{25} \cos 5 \omega_0 t - \frac{1}{49} \cos 7 \omega_0 t \dots$$

**Alternative Solution**

We can deduce the Fourier series from Fig. of Ex. 21.11 by shifting the vertical axis by  $\pi/2$  radians to the right. Replacing  $t$  by  $(t + \pi/2)$  in the Fourier series of Ex. 21.11, we get

$$f(t) = \frac{8V_m}{2} \sin \omega_0 t - \frac{1}{3^2} \sin 3 \omega_0 t + \frac{1}{5^2} \sin 5 \omega_0 t - \frac{1}{7^2} \sin 7 \omega_0 t \dots$$

$$= \frac{8V_m}{2} \cos \omega_0 t - \frac{1}{9} \cos 3 \omega_0 t + \frac{1}{25} \cos 5 \omega_0 t - \frac{1}{49} \cos 7 \omega_0 t \dots$$

**Example 21.15.** Obtain the Fourier series representation of the sawtooth waveform shown in Fig. 21.25 (a) and plot its spectrum.

Fig. 21.25

**Solution.** By inspection, we know that the average value of the wave is zero over a cycle because the height of the curve below and above the  $X$ -axis is the same hence,  $a_0 = 0$ . Moreover, it has odd symmetry so that  $a_n = 0$  i.e. there would be no cosine terms. The series will contain only sine terms.

$$\therefore f(\theta) = \sum_{n=1}^{\infty} b_n \sin n\theta \quad \text{where } b_n = \frac{1}{\pi} \int_0^{2\pi} f(\theta) \sin n\theta \, d\theta$$

The slope of curve is  $m = V/\pi$

$\therefore$  we get,  $f(\theta) = (V/\pi)\theta$ .

If we are the limit of integration from  $-\pi$  to  $+\pi$  then

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} \frac{V}{\pi} \sin n\theta \, d\theta = \frac{V}{\pi^2} \left[ \frac{1}{n} \sin n\theta - \frac{\cos n\theta}{n} \right]_{-\pi}^{\pi} = \frac{2V}{n^2} \cos n\pi$$

The above result has been obtained by making use of integration by parts as explained earlier.  $\cos n\pi$  is positive when  $n$  is even and is negative when  $n$  is odd and thus the signs of the coefficients alternate. The required Fourier series is

$$f(\theta) = \frac{2V}{\pi} \sin \theta - \frac{1}{2} \sin 2\theta + \frac{1}{3} \sin 3\theta - \frac{1}{4} \sin 4\theta + \dots$$

$$\text{or } f(t) = \frac{2V}{\pi} \sin \omega_0 t - \frac{1}{2} \sin 2\omega_0 t + \frac{1}{3} \sin 3\omega_0 t - \frac{1}{4} \sin 4\omega_0 t + \dots$$

As seen, the coefficients decrease as  $1/n$  so that the series converges slowly as shown by the line spectrum of Fig. 21.25 (b).

The amplitudes of the fundamental of first harmonic, second harmonic, third harmonic and fourth harmonic are  $(2/\pi), (2V/2\pi), (2V/3\pi)$  and  $(2V/4\pi)$  respectively.

### Tutorial Problem. 21.1

1. Determine the Fourier series for the triangular waveform shown in Fig. 21.26 (a)

(Network Theory and Design, AMIETE June 1990)

Fig. 21.26

$$\left[ \frac{1}{2} - \frac{4}{\pi^2} \cos \omega_0 t + \frac{1}{3^2} \cos 3 \omega_0 t + \frac{1}{5^2} \cos 5 \omega_0 t + \dots \right]$$

2. Find the values of the Fourier coefficients  $a_0$ ,  $a_n$  and  $b_n$  for the function given in fig. 21.26 (b).

$$\left[ a_0 = \frac{2}{3}; a_n = \frac{7}{n\pi} \sin \frac{2n\pi}{3}; b_n = \frac{7}{n\pi} \left( 1 - \cos \frac{2n\pi}{3} \right) \right]$$

3. Determine the trigonometric series of the triangular waveform shown in Fig. 21.27. Sketch its line spectrum.

Fig. 21.27

$$\frac{V_m}{2} - \frac{4V_m}{\pi^2} \cos^2 \omega t + \frac{1}{3^2} \cos 3 \omega t - \frac{1}{5^2} \cos 5 \omega t + \dots$$

4. Determine the Fourier series for the sawtooth waveform shown in Fig. 21.28.

Fig. 21.28

Fig. 21.29

$$\left[ f(t) = \frac{V_m}{2} + \frac{V_m}{\pi} (\sin\omega_0 t + \frac{1}{2} \sin 2\omega_0 t + \frac{1}{3} \sin 3\omega_0 t + \dots) \right]$$

5. Represent the full-wave rectified voltage sine waveform shown in Fig. 21.29 by a Fourier series.

$$\left[ f(t) = \frac{2V_m}{\pi} + \left( 1 + \frac{2}{3} \cos 2\omega t - \frac{2}{15} \cos 4\omega t + \frac{2}{35} \cos 6\omega t \dots \right) \right]$$

6. Obtain trigonometric Fourier series for the wave form shown in Fig. 21.30.

Fig. 21.30

Fig. 21.31

$$\left[ f(t) = -\frac{2V_m}{\pi} \left( \sin\omega_0 t + \frac{1}{2} \sin 2\omega_0 t + \frac{1}{3} \sin 3\omega_0 t + \frac{1}{4} \sin 4\omega_0 t \dots \right) \right]$$

7. Find the Fourier series for the sawtooth waveform shown in Fig. 21.31.

Fig. 21.32

$$\left[ f(t) = \frac{2}{\pi} \left( -\sin 2\pi t + \frac{1}{2} \sin 4\pi t - \frac{1}{3} \sin 6\pi t + \dots \right) \right]$$

8. For the waveform of Fig. 21.32, find the Fourier series terms up to the 5th harmonic.

(Network Theory Nagpur Univ. 1993)

$$\left[ V(t) = \frac{16}{\pi} \left( \sin t + \frac{2}{3} \sin 3t \right) + \frac{1}{5} \sin 5t + \dots \right]$$

9. Determine Fourier series of a repetitive triangular wave as shown in Fig. 21.33.

Fig. 21.33

(a) What is the magnitude of d.c. component?

(b) What is the fundamental frequency?

- (c) What is the magnitude of the fundamental?
- (d) Obtain its frequency spectrum.

(Network Theory Nagpur Univ.1993)

[(a) 5 V (b) 1 Hz (c) 10 / π volt]

10. Determine the Fourier series of voltage responses obtained at the o/p of a half wave rectifier shown in Fig. 21.34. Plot the discrete spectrum of the waveform.

(Elect. Network Analysis Nagpur Univ. 1993)

Fig. 21.34

$$\left[ V(t) = \frac{V_m}{\pi} + \frac{V_m}{2} \cos\omega_0 t + \frac{2V_m}{3\pi} \cos 10\pi t - \frac{2V_m}{15} \cos 20\pi t + \frac{2V_m}{35\pi} \cos 30\pi t \dots \right]$$

11. Determine the Fourier coefficients and plot amplitude and phase spectral.

(Network Analysis Nagpur Univ. 1993)

$$\left[ a_3 = 0, b_n = 0, a_1 = \frac{4V_m}{\pi}, a_2 = 0 \right]$$

$$\left[ a_3 = \frac{-4V_m}{3\pi}, a_4 = 0, a_5 = \frac{4V_m}{\pi} \right]$$

Fig. 21.35

### OBJECTIVE TESTS – 21

1. A given function  $f(t)$  can be represented by a Fourier series if it
  - (a) is periodic
  - (b) is single valued
  - (c) has a finite number of maxima and minima in any one period
  - (d) all of the above.
2. In a Fourier series expansion of a periodic function, the coefficient  $a_0$  represents its
  - (a) net area per cycle
  - (b) d.c value

- (c) average value over half cycle  
(d) average a.c value per cycle
3. If in the Fourier series of a periodic function, the coefficient  $a_0$  is zero, it means that the function has  
(a) odd symmetry  
(b) even quarter-wave symmetry  
(c) odd quarter-wave symmetry  
(d) any of the above.
4. A periodic function  $f(t)$  is said to possess odd quarter-wave symmetry if  
(a)  $f(t) = f(-t)$   
(b)  $f(-t) = -f(t)$   
(c)  $f(t) = -f(t + T/2)$   
(a) both (b) and (c).
5. If the average value of a periodic function over one period is zero and it consists of only odd harmonics then it must be possessing \_\_\_\_\_ symmetry.  
(a) half-wave  
(b) even quarter-wave  
(c) odd quarter-wave  
(d) odd.
6. If in the Fourier series of a periodic function, the coefficient  $a_0 = 0$  and  $a_n = 0$ , then it must be having \_\_\_\_\_ symmetry.  
(a) odd  
(b) odd quarter-wave  
(c) even  
(d) either (a) or (b).
7. In the case of a periodic function possessing half-wave symmetry, which Fourier coefficient is zero ?  
(a)  $a_n$  (b)  $b_n$   
(c)  $a_0$  (d) none of above.
8. A periodic function has zero average value over a cycle and its Fourier series consists of only odd cosine terms. What is the symmetry possessed by this function.  
(a) even  
(b) odd  
(c) even quarter-wave  
(d) odd quarter-wave
9. Which of the following periodic function possesses even symmetry ?  
(a)  $\cos 3t$  (b)  $\sin t$   
(c)  $t \cdot \cos 50t$  (d)  $(t + t^2 + t^3)$ .
10. If the Fourier coefficient  $b_n$  of a periodic function is zero, then it must possess \_\_\_\_\_ symmetry.  
(a) even  
(b) even quarter-wave  
(c) odd  
(d) either (a) and (b).
11. A complex voltage waveform is given by  $V = 120 \sin \omega t + 36(3\omega t + \pi/2) + 12 \sin(5\omega t + \pi)$ . It has a time period of  $T$  seconds. The percentage fifth harmonic contents in the waveform is  
(a) 12 (b) 10  
(c) 36 (d) 5
12. In the waveform of Q. 11 above, the phase displacement of the third harmonic represents a time interval of \_\_\_\_\_ seconds.  
(a)  $T/12$  (b)  $T/3$   
(c)  $3T$  (d)  $T/36$
13. When the negative half-cycle of a complex waveform is reversed, it becomes identical to its positive half-cycle. This feature indicates that the complex waveform is composed of  
(a) fundamental  
(b) odd harmonics  
(c) even harmonics  
(d) both (a) and (b)  
(e) both (a) and (c)
14. A periodic waveform possessing half-wave symmetry has no  
(a) even harmonics  
(b) odd harmonics  
(c) sine terms  
(d) cosine terms
15. The Fourier series of a wave form possessing even quarter-wave symmetry has only  
(a) even harmonics  
(b) odd cosine terms  
(c) odd sine terms  
(d) both (b) and (c).
16. The Fourier series of a waveform possessing odd quarter-wave symmetry contains only  
(a) even harmonics  
(b) odd cosine terms  
(c) odd cosine terms  
(d) none of above

## ANSWERS

## Learning Objectives

- Introduction
- Types of Transients
- Important Differential Equations
- Transients in R-L Circuits (D.C.),
- Short Circuit Current
- Time Constant
- Transients in R-L Circuits (A.C.)
- Transients in R-C Series Circuits (D.C.)
- Transients in R-C Series Circuits (A.C.)
- Double Energy Transients

## TRANSIENTS

↑ Transients are the surges or spikes in electric currents and voltages which are transmitted through power or data lines. The gadget shown in the above picture is claimed to protect the equipment against such surges or spikes

## 22.1. Introduction

It is quite an easy job to calculate the steady current, which flows in a circuit, when it is connected to a d.c. generator or a battery. Similarly, the alternating current which flows in a circuit when connected to an alternator can also be calculated by the various method discussed in Chapters 13 and 14. These currents are known as *steady* currents because in such cases, it is assumed that (i) the circuit components are constant and (ii) the circuit has been connected to the generator long enough for any disturbance produced on initial switching, to resolve itself.

In general, transients disturbances are produced whenever

- (a) an apparatus or circuit is *suddenly* connected to or disconnected from the supply,
- (b) a circuit is shorted and
- (c) there is a *sudden* change in the applied voltage from one finite value to another.

We will now discuss the transients produced whenever different circuits are suddenly switched on or off from the supply voltage. In each case, we will assume that the resultant current consists of two parts (i) a final steady-stage or normal current and (ii) a transient current superimposed on the steady-stage current.

It is essential to remember that the transient currents are not driven by any part of the applied voltage but are entirely associated with the changes in the stored energy in inductors and capacitors. Since there is no stored energy in resistors, *there are no transients in pure resistive circuits.*

## 22.2. Types of Transients

There are *single-energy* transients and *double-energy* transients. Single-energy transients are those in which only one form of energy, either electromagnetic or electrostatic is involved as in  $R-L$  and  $R-C$  circuits.

However, double-energy transients are those in which both electromagnetic or electrostatic is involved as in  $R-L-C$  circuits Transient disturbances may be further classified as follows :

- (a) **Initiation Transients** : These are produced when a circuit, which is originally dead, is energised.
- (b) **Subsidence Transients** : These are produced when an energised circuit is rapidly de-energised and reaches an eventual steady-stage of zero current or voltage, as in the case of short-circuiting an  $R-L$  or  $R-C$  circuit suddenly.
- (c) **Transition Transients** : These are due to sudden but energetic changes from one steady state to another.
- (d) **Complex Transients** : These are produced in a circuit which is simultaneously subjected to two transients due to two independent disturbances or when the disturbing force producing the transients is itself variable.
- (e) **Relaxation Transients** : In these transients, the transition occurs cyclically towards states, which when reached, become unstable themselves.

A distinction may also be made between free and forced transients which are produced due to the applied voltage being itself transient.

## 22.3. Important Differential Equations

Some of the important differential equations, used in the treatment of single and double energy transients, are given below. We will consider both first-order and second-order differential equations.

**1. First Order Equations**

(i) Let  $\frac{dy}{dx} + ay = 0$  where  $a$  is a constant.

Its solution is  $y = k e^{-ax}$  where  $k$  is the constant of integration whose value can be found from the boundary conditions *i.e.* conditions prevalent at the instant when the voltage to a circuit is applied or excluded.

(ii) If  $\frac{dy}{dx} + ay = b$  where  $a$  and  $b$  are constants, then solution is  $y = \frac{b}{a} + k e^{-ax}$

The value of  $k$  can again be found from boundary conditions.

(iii) If  $\frac{dy}{dx} + Ay = B$

where  $A$  and  $B$  are not constants but are functions of  $x$ , then the solution is given by

$$y e^{A dx} = \int B dx e^{A dx} + k e^{A dx}$$

If  $A = a = \text{constant}$ , then the above equation simplifies to

$$y e^{ax} = \int B dx e^{ax} + k e^{ax}$$

**2. Second Order Equations**

(i) Suppose  $\frac{d^2y}{dx^2} + a \frac{dy}{dx} + by = 0$  where  $a$  and  $b$  are constants, then the solution is

$$y = k_1 e^{\lambda_1 x} + k_2 e^{\lambda_2 x}$$

where  $\lambda_1$  and  $\lambda_2$  are constants of integration and whose values are,

$$\lambda_1 = \frac{-a}{2} \pm \sqrt{\frac{a^2}{4} - b} \quad \text{and} \quad \lambda_2 = \frac{-a}{2} \mp \sqrt{\frac{a^2}{4} - b}$$

- (a) If  $a^2/4 > b$ , the roots are real and the above solution can be applied without any difficulty.
- (b) If  $a^2/4 < b$ , the radicals contain a negative quantity. In that-case, the solution is given by

$$y = e^{-\frac{a}{2}x} (k_3 \sin \lambda_0 x + k_4 \cos \lambda_0 x)$$

where  $k_3$  and  $k_4$  are the new constants of integration and

$$\lambda_0 = \sqrt{b - \frac{a^2}{4}}$$

- (c) If  $a^2/4 = b$ , then both roots are equal and each is  $= -a/2$ .

Hence, in this case, the solution becomes  $y = k_5 e^{\lambda t} + k_6 t \cdot e^{\lambda t}$

(ii) Let  $\frac{d^2y}{dx^2} + a \frac{dy}{dx} + by = c$

where  $a$ ,  $b$  and  $c$  are constant. In this case also, the solution will again depend on the root as discussed above.

$$y = k_1 e^{\lambda_1 x} + k_2 e^{\lambda_2 x} + c/b$$

(iii) (a) Let the differential equation be given by

$$\frac{d^2y}{dx^2} + a \frac{dy}{dx} + by = u$$

where  $a, b$  are constants but  $u$  is a particular function of the variable  $x$ . The solution of such an equation consists of a **particular integral** and a complementary function.

(b) Let  $y$  be a sinusoidal function of  $x$ , then

$$\frac{d^2y}{dx^2} + a\frac{dy}{dx} + by = c \sin \omega t$$

In this case, particular integral is

$$y_1 = \frac{c}{\sqrt{a^2 + b^2}} \cos x \tan^{-1} \frac{b}{a}$$

The complementary function is given by

$$y_2 = k_1 e^{p_1 x} + k_2 e^{p_2 x} \text{ where } p_1 = \frac{a}{2} + \sqrt{\frac{a^2}{4} - b} \text{ and } p_2 = \frac{a}{2} - \sqrt{\frac{a^2}{4} - b}$$

The complete solution for the above equation is  $y = y_1 + y_2$

Further treatment is the same as for case 2 (i) above.

### 22.4. Transients in R-L Circuits (D.C.)

If  $i, I_s$  and  $i_t$  be the resultant current, steady-state current and transient current respectively in R-L circuit of Fig. 22.1 (a), then by superimposition, the equation for the resultant current, for the duration of initiation transient, is

Fig. 22.1

$$i = I_s + i_t$$

... (i)

Since the applied voltage  $V$  drives the steady-state current, hence

$$I_s = V/R$$

Since the transient current  $i_t$  is not associated with any voltage,

$$\therefore i_t R + L \frac{di_t}{dt} = 0$$

... (ii)

or  $\frac{di_t}{dt} = -\frac{R}{L} i_t$  ... (iii)

or  $\frac{di_t}{i_t} = -\frac{R}{L} dt \therefore \log_e i_t = -\frac{R}{L} t + K^*$  ... (iv)

where  $K$  is the constant of integration whose value may be found from the initial conditions.

Now when  $t = 0, i_t = I_0$  (say). Then from Eq. (iv) above we get,  $\log_e I_0 = 0 + K$

\*  $\log_e x$  is written as  $\log x$ . Obviously,  $\log x = 2.3 \log_{10} x$ .

Putting this value of  $K$  in Eq. (iv), we have

$$\log i_t - \log I_0 = \frac{R}{L}t \text{ or } \log i_t / I_0 = \frac{R}{L}t$$

$$\therefore i_t = I_0 e^{-t/\lambda} \quad \dots (v)$$

where  $\lambda = L/R$  is called the **time-constant** of the circuit. Its reciprocal  $R/L$  is called the **damping coefficient** of the circuit. The current decreases exponentially as shown in Fig. 22.1 (b). From Eq. (i) and (v), we have

$$i = I_s + I_0 e^{-t/\lambda} \quad \dots (vi)$$

If the time is reckoned when the voltage  $V$  is applied, so that when  $t = 0, i = 0$ , then from equation (vi), we get

$$0 = I_s + i_0 e^{-0} = I_s + I_0 \quad \therefore I_0 = -I_s = -\frac{V}{R}$$

In that case, Eq. (vi) becomes

$$i = \frac{V}{R} - \frac{V}{R} e^{-t/\lambda} \quad \dots (vii)$$

$$= \frac{V}{R} (1 - e^{-t/\lambda}) \quad \dots (viii)$$

Curves for  $I_s$  and  $i_t$  have been plotted in Fig. 22.1 (b). The curve for resultant current has been obtained by the superposition of steady-state current  $I_s (= V/R)$  and transient current

Fig. 22.2

$$i_t = \frac{V}{R} e^{-t/\lambda}$$

Theoretically, the transient current  $i_t$  takes infinite time to die off but, in practice, it disappears in a very short time.

The values of resultant, steady-state and transient voltages across the resistor can be found by multiplying Eq. (vii) by  $R$  and are shown in Fig. 22.2. The e.m.f. of self-induction  $-L di/dt$  is only transient in nature and equals  $i_t R$  as seen from Eq. (ii) above.

### 22.5. Short Circuit Current

After some time, the transient current would disappear and the only current flowing in the circuit would be the steady-state current  $I_s = V/R$ . Let the  $R-L$  circuit be closed upon itself *i.e.* be short-circuited by shifting the switch [Fig. 22.1 (a)] to position 2. Since the voltage  $V$  has been excluded from the circuit, the trapped current  $I_s$  will immediately cease to be a steady-state current, but on the other hand, will become the initial value  $I_0$  of a new subsidence transient current  $i_t$ .

Large-capacity short-circuit current generator

If time is measured at the instant of short-circuit, so that when  $t = 0$ , the current is  $I_s = V/R$ , then Eq. (v) becomes

$$i_t = \frac{V}{R} e^{-t/\lambda} \quad \dots (ix)$$

This equation has been plotted in Fig. 22.3. The only voltage acting in the circuit is that due to self-induction *i.e.*  $-L di/dt$  which equals  $iR$ .

Fig. 22.3

## 22.6. Time Constant

The time constant of a circuit is defined as the time it would take for the transient current to decrease to zero, if the decrease were linear instead of being exponential.

In other words, it is the time during which the transient current would have decreased to zero, had it maintained its initial rate of decrease.

The initial rate of decrease can be found by differentiating Eq. (vi) and putting  $t = 0$

$$\therefore \frac{di_t}{dt} = \frac{I_0}{\lambda} e^{-t/\lambda} \quad \frac{di_t}{dt} \Big|_{t=0} = \frac{I_0}{\lambda}$$

If the rate of decrease were constant throughout and equal to  $-I_0/\lambda$ , then the straight line showing the relation between  $i_t$  and  $t$  would be given by

$$i_t = -\frac{I_0}{\lambda} t$$

The time-period would be equal to the sub-tangent  $OT$  drawn to the exponential curve of Fig. 22.3 at  $i_t = I_0$  *i.e.* at the beginning of the curve.

If we put  $t = \lambda$  in Eq. (v), then  $i_t = I_0 e^{-1} = I_0/e = I_0/2.718 = 0.37 I_0$

Hence, time period of a circuit is the time during which the transient current decreases to 0.37 of its initial value.

**Example 22.1.** A coil having a resistance of  $30 \Omega$  and an inductance of  $0.09 \text{ H}$  is connected across a battery of  $20 \text{ V}$ . Plot the current and its two components. Assume that  $t = 0$  when the circuit is completed. (Electromechanic Allahabad Univ. 1992)

Fig. 22.4

**Solution.** The two components of the circuit current are (i) steady current  $I_s = V/R = 20/30 = 2/3 \text{ A} = 667 \text{ mA}$  and (ii) Transient current  $i_t = -(V/R)e^{-t/\lambda}$ .

Total current is  $i = I_s + i_t$ . Let us find the value of transient current after various time intervals. In the present case,  $\lambda = L/R = 0.09/30 = 0.003$  second = 3 millisecond.

The values of  $i_t$  and  $i$  at various times are tabulated below. Value of  $i = I_s + i_t$

$t$ (ms)	$e^{-t/\lambda}$	$i_t$ (mA)	$i$	$t$ (ms)	$e^{-t/\lambda}$	$i_t$ (mA)	$i$
0.0	1.000	-667	0	2.5	0.435	-290	377
0.5	0.847	-565	102	3.0	0.368	-244	423
1.0	0.716	-477	190	3.5	0.311	-208	459
1.5	0.606	-405	262	4.0	0.264	-176	491
2.0	0.514	-344	323	4.5	0.223	-148	519

It is seen that whereas transient current decreases exponentially, total circuit current increases exponentially as expected (Fig. 22.4).

**Example 22.2.** A circuit of resistance  $10 \Omega$  and inductance  $0.1 \text{ H}$  in series has a direct voltage of  $200 \text{ V}$  suddenly applied to it. Find the voltage drop across the inductance at the instant of switching on and at  $0.01$  second. Find also the flux-linkages at these instants.

(Basic Electricity, Bombay Univ.)

**Solution. (i) Switching instant**

At the instant of switching on,  $i = 0$ , so that  $iR = 0$  hence all applied voltage must drop across the inductance only. Therefore, voltage drop across inductance = **200 V**.

Since at this instant  $i = 0$ , there are no flux-linkages of the coil.

**(ii) When  $t = 0.01$  second**

As time passes, current grows so that the applied voltage is partly dropped across the resistance and partly across the coil. Let us first find  $iR$  drop for which purpose, we need the value of  $i$  at  $t = 0.01$  second.

Now, time period of the circuit is  $\lambda = L/R = 0.1/10 = 0.01$  second. Since the given time happens to be equal to time constant,

$$\therefore i = (200/10) \times 0.632 = 12.64 \text{ A}; iR = 12.64 \times 10 = \mathbf{126.4 \text{ V}}$$

$$\text{Drop across inductance} = \sqrt{200^2 - 126.4^2} = \mathbf{155 \text{ V}}$$

$$\text{Now, } L = N \Phi / i \quad \text{or} \quad N\Phi = Li$$

$$\therefore \text{Flux-linkages } Li = 0.1 \times 12.64 = \mathbf{1.264 \text{ Wb-turns.}}$$

**Example 22.3.** A coil of  $10 \text{ H}$  inductance and  $5 \Omega$  resistance is connected in parallel with a  $20 \Omega$  resistor across a  $100\text{-V}$  d.c. supply which is suddenly disconnected. Find

- the initial rate of change of current after switching.
- the voltage across the  $20 \Omega$  resistor initially and after  $0.3 \text{ s}$ .
- the voltage across the switch contacts at the instant of separation and
- the rate at which the coil is losing stored energy  $0.3$  second after switching.

**Solution. (a)** Since the steady-state current is zero,  $i = I_0 e^{-t/\lambda}$

Now, when  $t = 0$ , current is  $= 100/5 = 20 \text{ A}$ . It means the current flowing through the coil immediately before opening the switch is  $20 \text{ A}$ .

$$\therefore I_0 = 20 \text{ A}$$

Hence, the above equation becomes  $i = 20e^{-t/\lambda}$

$$\text{Now } \lambda = L/R = 10/25 = 1/2.5 \quad \therefore i = 20e^{-2.5t}$$

$$\frac{di}{dt} \bigg|_{t=0} (20 - 2.5e^{2.5t})_{t=0} = -50 \text{ A/s}$$

The negative sign merely shows that the current is decreasing.

(b) After the supply has been disconnected, the current through the  $20\text{-}\Omega$  resistor is  $i$  since it is in series with the coil.

$$\text{Initial p.d. across the } 20\Omega \text{ resistor} = (\text{current at } t=0) \times 20 = 20 \times 20 = \mathbf{400 \text{ V}}$$

$$\text{Current through the resistor after 0.3 second} = 20e^{-2.5 \times 0.3} = 9.45 \text{ A}$$

$$\therefore \text{Voltage across the resistor after 0.3 second} \\ = (\text{current at } t = 0.3 \text{ second}) \times 20 = 9.45 \times 20 = \mathbf{189 \text{ V}}$$

(c) The e.m.f. induced in the coil at break tends to maintain the current through it in the original direction. Hence, the direction of the current through  $20\text{-}\Omega$  resistor is upwards so that the p.d. across the switch contacts will be the *sum* of supply voltage and the voltage across  $20\text{-}\Omega$  resistor.

$$\therefore \text{Initial voltage across switch contacts} = 400 + 100 = \mathbf{500 \text{ V}}$$

(d) The rate of loss of energy = power = induced e.m.f. in coil  $\times$  current (after 0.3 s)

$$L \frac{di}{dt} \bigg|_{t=0.3} \text{ (after 0.3 second)}$$

Now, after 0.3 second,  $i = 9.45 \text{ A}$

$$\text{Value of } di/dt \text{ after 0.3 second} = -20 \times 2.5 \times e^{-0.75} = -23.6 \text{ A/second}$$

$$\therefore \text{Rate of loss of energy} = -10 \times 23.6 \times 9.45 = -2,230 \text{ joule/second}$$

## 22.7. Transients in R-L Circuits (A.C.)

Let a voltage given by  $v = V_m \sin(\omega t + \Psi)$  be *suddenly* applied across an  $R$ - $L$  circuit [Fig. 22.5 (a)] at a time when  $t = 0$ . It means that the voltage is applied when it is passing through the value  $V_m \sin \Psi$ . Since the contact may be closed at any point of the cycle, angle  $\Psi$  may have any value lying between zero and  $2\pi$  radians. The resultant current, as before, is given by

$$i = i_s + i_t$$

Fig. 22.5

The value of steady-state current is found by the normal circuit theory. The peak steady-state current is given by

$$I_m = \frac{V_m}{\sqrt{R^2 + X_L^2}} = \frac{V_m}{Z}$$

where  $\sqrt{R^2 + X_L^2}$  is the impedance of the circuit. This current lags behind the applied voltage by an angle  $\phi$  such that  $\tan \phi = X_L/R$  or  $\phi = \tan^{-1}(X_L/R)$

Hence, the equation for the instantaneous value of the steady-state current becomes

$$i_s = I_m \sin(\omega t + \Psi - \phi)$$

As before, the transient current is given by

$$i_t = I_0 e^{-t/\lambda} \quad \therefore i = I_m \sin(\omega t + \Psi - \phi) + I_0 e^{-t/\lambda} \quad \dots (i)$$

Now, when  $t = 0$ ,  $i = 0$ , hence putting these values in Eq. (i) above, we get

$$0 = I_m \sin(\Psi - \phi) + I_0 \quad \therefore I_0 = -I_m \sin(\Psi - \phi)$$

Hence Eq. (i) can be written as

$$i = I_m \sin(\omega t + \Psi - \phi) - I_m \sin(\Psi - \phi) e^{-t/\lambda} \quad \dots (ii)$$

From the above, it is seen that the value of  $I_0$  and hence the size of the transient current depends on angle  $\Psi$  i.e. it depends on the instant in the cycle at which the circuit is closed. We will consider the following three cases :

#### Case 1

When  $t = 0$ , let the voltage pass through its zero value and become positive i.e. let  $\Psi = 0$ . In that case, putting this value of  $\Psi$  in Eq. (ii), we get

$$i = I_m \sin(\omega t - \phi) - I_m \sin(-\phi) e^{-t/\lambda} = I_m [\sin(\omega t - \phi) + \sin \phi e^{-t/\lambda}]$$

This is shown in Fig. 22.5 (b). It is seen that maximum instantaneous peak current  $OB$  is larger than the normal peak current  $OA$ .

#### Case 2

Let  $t = 0$  when voltage is passing through its value  $V_m \sin(\phi)$  so that  $\Psi = \phi$  or  $\Psi - \phi = 0$

In that,  $I_0 = 0$ , there is no transient current at the time of switching on (i.e.  $i_t = 0$ ). It corresponds to the contacts closing at the instant when the steady state current itself is zero.

#### Case 3

When  $t = 0$ , let the voltage be passing through

$$V_m \sin \frac{\pi}{2} \quad \text{i.e.} \quad \frac{V_m}{2} \quad \text{and} \quad \frac{V_m}{2} / 2$$

In this case, the transient [as found from Eq. (ii)] would be given by

$$i_t = I_m \sin \frac{\pi}{2} \cdot e^{-t/\lambda} - I_m e^{-t/\lambda}$$

Under these conditions, the transient would have its maximum possible initial value.

**Example 22.4.** A 1.0 H choke has a resistance of 50  $\Omega$ . This choke is supplied with an a.c. voltage given by  $e = 141 \sin 314 t$ . Find the expression for the transient component of the current flowing through the choke after the voltage is suddenly switched on.

(Principles of Elect. Engg-II, Jadavpur Univ.)

**Solution.** The equation of the transient component of the current is (Art. 22.7 Case 1)

$$i_t = I_m \sin \phi e^{-t/\lambda}$$

Here,

$$\lambda = L/R = 1/50 = 0.02 \text{ second}; \mathbf{Z} = 50 + j314 = 318 \angle 80.95^\circ$$

$$I_m = V_m/Z = 141/318 = 0.443 \text{ A}; \quad \sin 80.95^\circ = 0.9875$$

$$\therefore i_t = 0.443 \times 0.9875 e^{-t/0.02} = 0.4376 e^{-t/0.02}$$

**Example 22.5.** A 50-Hz sinusoidal voltage of maximum value of 400 V is applied to a series circuit of resistance  $10 \Omega$  and inductance  $0.1 \text{ H}$ . Find an expression for the value of the current at any instant after the voltage is applied, assuming that voltage is zero at the instant of application. Calculate its value  $0.02$  second after switching on **(Electric Circuit, Punjab Univ. 1990)**

**Solution.** In such cases, as seen from Art. 22.7 (Case 1), the current consists of a steady-state component and a transient component. The equation of the resultant current is

$$i = \underbrace{I_m \sin(\omega t - \phi)}_{\text{steady-state current}} + \underbrace{I_m \sin \phi e^{t/\lambda}}_{\text{transient current}}$$

where  $I_m = V_m / Z$ ;  $\phi = \tan^{-1} (X_L / R)$ ;  $\lambda = L / R$  second

$$R = 10 \Omega; X_L = 314 \times 0.1 = 31.4 \Omega; \mathbf{Z} = 10 + j31.4 = 33 \angle 72.3^\circ$$

$$I_m = 400 / 33 = 12.1 \text{ A}; \quad \phi = 72.3^\circ = 1.26 \text{ rad.}$$

$$\sin \phi = \sin 72.3^\circ = 0.9527; \quad \lambda = 0.1 / 10 = 1 / 100 \text{ second}$$

$$i = 12.1 \{ \sin (314 t - 1.262) + 0.9527 e^{0.01 t} \}$$

Substituting  $t = 0.02$  second, we get

$$i = 12.1 \{ \sin (314 \times 0.02 - 1.262) + 0.9527 e^{-2} \}$$

$$= 12.1 \{ \sin 5.02 + 0.9527 e^{-2} \} = 12.1 \{ \sin 288^\circ + 0.9527 e^{-2} \}$$

$$= 12.1 \{ -\sin 72^\circ + 0.9527 \times 0.1353 \} = 12.1 \{ -0.9511 + 0.1289 \} = \mathbf{-9.95 \text{ A}}$$

**Example 22.6.** An alternating voltage  $v = 400 \sin (314 t + \Psi)$  is suddenly applied across a coil of resistance  $0.2 \Omega$  and inductance  $6.36 \text{ mH}$ . Determine the first peak value of the resultant current when the transient current has maximum value.

**Solution.** Obviously,  $\omega = 314 \text{ rad/s}$

$$X_L = \omega L = 314 \times 6.36 \times 10^{-3} = 2 \Omega$$

Coil impedance  $\mathbf{Z} = 0.2 + j2 \sim 2 \angle 84.3^\circ$

Max. value of steady-state current =  $400/2 = 200 \text{ A}$

As seen from Art. 22.7, the maximum value of transient current will occur when

$\Psi = \phi \pm \pi/2$  where  $\phi = 84.3^\circ$  i.e. the phase angle of the current w.r.t. voltage

$$\therefore \Psi = 84.3^\circ - 90^\circ = -5.7^\circ$$

$$\therefore \text{resultant current, } i = 400 \sin (314 t - 90^\circ) + I_0 e^{-31.4 t}$$

Now, at  $t = 0$ ,  $i = 0$

$$\therefore 0 = 400 \sin (-90^\circ) + I_0$$

$$\therefore I_0 = 400 \text{ A}$$

Hence, the above equation becomes

$$i = 400 \sin (\omega t - 90^\circ) + 400 e^{-31.4 t}$$

The procedure for determining an exact solution for the first peak of the resultant current is first to differentiate the above expression, next to equate the result to zero and then to solve the resulting expression graphically for  $t$ . However, sufficiently accurate result can be obtained by determining the instant at which steady-state current reaches its first positive peak value and then

to add to it the value of the transient current at this instant. The first peak value of steady-state current occurs when

$$(314 t - 90^\circ) = \pi/2 \text{ rad ; i.e. when } t = \pi/314 = 0.01 \text{ second}$$

At this time,  $i_t = 400 e^{-0.314} = 292 \text{ A}$

$\therefore$  resultant current  $i$  at this time =  $200 + 292 = \mathbf{492 \text{ A}}$

### 22.8. Transients in R-C Weeries Circuits (D.C.)

When a d.c. voltage  $V$  is **suddenly** applied to an  $R$ - $C$  series circuit (Fig. 22.6), the voltage  $v_c$  across the capacitor rises from zero value to the steady-state value  $V$ . If  $v_c$  is the voltage across capacitor,  $V_{ct}$  the transient voltage, then

$$v_c = V + v_{ct} \quad \dots (i)$$

The charging current is maximum at the beginning but then is reduced to zero so that there is no steady-state current but a transient one.

Since the transient current is not associated with any applied voltage, hence

$$i_t R + v_{ct} = 0 \quad \dots (ii)$$

Now, capacitor voltage  $v_{ct} = q_t/C$

Hence, Eq. (ii) becomes

$$i_t R + \frac{q_t}{C} = 0$$

or  $R \cdot \frac{di_t}{dt} + \frac{1}{C} \cdot \frac{dq_t}{dt} = 0$  or  $\frac{di_t}{dt} = -\frac{1}{CR} \frac{dq_t}{dt} = -\frac{1}{CR} i_t$  ( $dq_t/dt = i_t$ )

$$\therefore \frac{di_t}{i_t} = -\frac{dt}{CR}; \quad \text{As before } i_t = I_0 e^{-t/CR} = I_0 e^{-t/\lambda}$$

where  $CR = \lambda =$  time constant. The reciprocal  $1/CR$  is known as damping coefficient.

#### (i) Charging Current

Fig. 22.6

Fig. 22.7

When  $t = 0$ , transient current  $i_t = I_0$ , so that from Eq. (ii)  $v_{ct} = -I_0 R$ . Moreover, when  $t = 0$ ,  $v_c = 0$ , hence from Eq. (i),  $v_{ct} = -V$

Combining these results, we get

$$I_0 = V/R$$

$$\therefore i_t = I_0 e^{-t/\lambda} = \frac{V}{R} e^{-t/\lambda}$$

This is plotted in Fig. 22.7 (a)

The transient voltage across the resistor  $R$  is given by

$$i_t R = \frac{V}{R} e^{-t/\lambda} \times R = V e^{-t/\lambda} \dots \text{Fig. 19.7 (b)}$$

From Eq. (ii) the value of transient voltage across the capacitor is  $v_a = -i_t R$

Hence, Eq. (i) becomes

$$v_c = V - i_t R = V - V e^{-t/\lambda}$$

or

$$v_c = V(1 - e^{-t/\lambda}) \dots \text{(iii)}$$

The voltage across the capacitor  $v_c$  which is the sum of the transient voltage  $v_{ct}$  and steady-state  $V$  has been plotted in Fig. 22.7 (c).

The charge across the capacitor is given by

$$q = v_c = CV(1 - e^{-t/\lambda}) \text{ or } q = Q(1 - e^{-t/\lambda}) \quad (\because Q = CV)$$

### (ii) Discharge Current

When the capacitor has become fully charged so that charging current has ceased, then the  $R$ - $C$  circuit is short-circuited by shifting the switch  $S$  from position 1 to position 2 (Fig. 22.6). On doing so, a transient discharge current will start flowing immediately. If time is reckoned from the instant of short-circuit, then when  $t = 0$ ,  $i_t = I_0$ , hence from Eq. (ii) above  $v_{ct} = -I_0 R$ . Moreover, when  $t = 0$ ,  $v_c = V$ . However, since there is no steady-state voltage across the capacitor, from Eq. (i), we get  $v_c = v_{ct}$ . Combining these results, we get

$$I_0 = -V/R$$

$$\therefore i_t = -\frac{V}{R} e^{-t/\lambda}$$

It is plotted in Fig. 22.8 (a). The negative sign shows that discharge current flows in a direction opposite to that in which the charging current flows. That is why the curve has been drawn below the  $X$ -axis. It may be noted that the only voltage in the circuit is  $v_{ct}$  which equals  $-i_t R$ .

Fig. 22.8

**Example 22.7.** In a simple saw-tooth generator circuit with the thyatron switches on at 150 V and switches off at 10 V. If this circuit is supplied with 250 V d.c. source; find the time period of saw-tooth wave. The resistance and capacitance have the values of 10 k $\Omega$  and 1  $\mu$ F respectively.

(Principles of Elect. Engg-II, Jadavpur Univ.)

**Solution.** With reference to Fig. 22.9, let

$V =$  applied voltage

$v_{c1} =$  switching-off voltage of the thyatron = 10 V

$v_{c2} =$  switching-on voltage of the thyatron = 150 V

Now,  $v = V(1 - e^{-t/\lambda})$

$$\therefore v_{c1} = V(1 - e^{-t_1/\lambda}) \quad \dots (i)$$

$$V(1 - e^{-(t_1+T)/\lambda}) = v_{c2} \quad \dots (ii)$$

where  $T$  is the time-period of the saw-tooth wave. From Eq. (i) and (ii), we get

$$T = \lambda \log_e (V - v_{c1}) / (V - v_{c2})$$

Now  $\lambda = CR = 10^4 \times 10^{-6} = 10^{-2}$  second

$$V - v_{c1} = 250 - 10 = 240 \text{ V}; V - v_{c2} = 250 - 150 = 100 \text{ V}$$

$$\therefore \frac{V - v_{c1}}{V - v_{c2}} = \frac{240}{100} = 2.4 \quad \therefore T = 10^{-2} \log_c 2.4 = \mathbf{0.00875 \text{ second}}$$

Fig. 22.9

**Example 22.8.** A simple neon-tube time base for a cathode-ray oscillography employs a  $300 \text{ k}\Omega$  and a  $0.016 \mu\text{F}$  capacitor. The striking and extinction voltages of the neon-tube are 170 V and 140 V respectively. Calculate the frequency of the time base if the supply voltage is 200 V.

**Solution.** The voltage across the capacitor increases according to the equation

Fig. 22.10

$$v_c = V(1 - e^{-t/CR})$$

It is shown in Fig. 22.10 (b)

$$\therefore v_{c1} = V(1 - e^{-t_1/CR}) \quad \dots (i)$$

$$v_{c2} = V(1 - e^{-(t_1+T)/CR}) \quad \dots (ii)$$

From eq. (i) and (ii), we get

$$T = CR \log_e (V - v_{c1}) / (V - v_{c2})$$

Now

$$\lambda = CR = 0.016 \times 10^{-6} \times 300 \times 10^3 = 4.8 \times 10^{-3} \text{ second}$$

$$V - v_{c1} = 200 - 140 = 60 \text{ V and } V - v_{c2} = 200 - 170 = 30 \text{ V}$$

A view of the neon tube experiment

$$\therefore T = 4.8 \times 10^{-3} \log 60/30 = 1/300 \text{ second}$$

$$\therefore \text{Frequency of time base} = 1/T = \mathbf{300 \text{ Hz}}$$

### 22.9. Transients in R-C Series Circuits (A.C.)

In this case, the resultant currents can be determined in the same way as for an  $R$ - $L$  circuit (Art. 22.7). It is given by

Fig. 22.11

$$i = i_s + i_t = I_m \sin(\omega t + \psi + \phi) + I_0 e^{-t/\lambda} \quad \text{where} \quad I_m = V_m / \sqrt{R^2 + X_C^2}$$

$$\text{and} \quad v = V_m \sin(\omega t + \psi)$$

The value of  $I_0$  as found from initial known conditions ( $t=0, i=0$ ) is given by  $I_0 = -I_m \sin(\psi + \phi)$

Hence, the resultant current becomes

$$i = I_m \sin(\omega t + \psi + \phi) - I_m \sin(\psi + \phi) e^{-t/\lambda}$$

As shown in Fig. 22.11, the resultant current at the moment of switch closing is  $OA$  and is made up of steady-state current  $OC$  and transient current  $OB$ .

### 22.10. Double Energy Transients

In an  $R$ - $L$ - $C$  circuit, both electromagnetic and electrostatic energies are involved, hence any sudden change in the conditions of the circuit involves the redistribution of these two forms of energy. The transient currents produced due to this redistribution are known as double-energy transients. The transient current produced may be unidirectional or a decaying oscillatory current.

In an  $R$ - $L$ - $C$  circuit, the transient voltages across the three circuit parameters are  $i_t R$ ,  $L di_t / dt$  and  $q_t / C$ . Hence, the equation of the transient voltage is

$$i_t R + L \frac{di_t}{dt} + \frac{q_t}{C} = 0 \quad \dots (i)$$

Differentiating the above equation and putting  $i_t$  for  $dq_t / dt$ , we get

$$\frac{d^2 i_t}{dt^2} + \frac{R}{L} \frac{di_t}{dt} + \frac{1}{LC} i_t = 0 \quad \dots (ii)$$

This is a linear differential equation of the second order with constant coefficient like 2 (i) given in Art. No. 22.3. Its solution is given by

$$i_t = k_1 e^{\lambda_1 t} + k_2 e^{\lambda_2 t} \quad \dots \text{ (iii)}$$

where  $k_1$  and  $k_2$  are constants whose values are found from the boundary conditions. The values of  $\lambda_1$  and  $\lambda_2$  are given by

$$\lambda_1 = -\frac{R}{2L} - \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}} \quad \text{and} \quad \lambda_2 = -\frac{R}{2L} + \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}}$$

Depending on the value of  $\lambda_1$  and  $\lambda_2$ , four different conditions of the circuit are distinguishable. We will now examine these four conditions in the case of an  $R$ - $L$ - $C$  circuit.

**Case 1. Loss-free Circuit,  $R = 0$  i.e. Undamped**

$$\text{In this case, } \lambda_1 = \sqrt{-\frac{1}{LC}} = j - 1\sqrt{LC} = -j\omega \quad \text{and} \quad \lambda_2 = -\sqrt{-\frac{1}{LC}} = -j - 1\sqrt{LC} = -j\omega$$

Hence, Eq. (iii) given above becomes

$$\begin{aligned} i_t &= k_1 e^{j\omega t} + k_2 e^{-j\omega t} = k_1 (\cos \omega t + j \sin \omega t) + k_2 (\cos \omega t - j \sin \omega t) \\ &= (k_1 + k_2) \cos \omega t + j(k_1 - k_2) \sin \omega t \end{aligned}$$

$$\text{or} \quad i_t = A \cos \omega t + B \sin \omega t \quad \dots \text{ (iv)}$$

where  $A = k_1 + k_2$  and  $B = j(k_1 - k_2)$

Eq. (iv) can be still further simplified to

$$i_t = I_m \sin(\omega t + \phi) \quad \dots \text{ (v)}$$

where  $I_m = \sqrt{A^2 + B^2}$  and  $\phi = \tan^{-1}(A/B)$

As seen from Eq. (v), the transient current in this case is sinusoidal wave of constant peak value and frequency  $f = 1/2\pi\sqrt{LC}$  as shown in Fig. 22.12 (a). The values of two constant terms  $I_m$  and  $\phi$  can be determined from any two known initial circuit conditions which are (i) the initial current in the inductance and (ii) the initial voltage across the capacitor.

**Case 2. Low-loss Circuit:  $\frac{R^2}{4L^2} < \frac{1}{LC}$  i.e. Under-damped**

In this case,  $\lambda_1$  and  $\lambda_2$  would be conjugate complex numbers because the term under the square root sign in each case would be negative.

$$\therefore \lambda_1 = -\frac{R}{2L} + j\sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}}$$

$$\text{If } a = \frac{R}{2L} \text{ and } \omega = \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}} \text{ then } \lambda_1 = -a + j\omega \text{ and } \lambda_2 = -a - j\omega$$

Putting these values in equation (v), we get

$$i_t = k_1 e^{(-a+j\omega)t} + k_2 e^{(-a-j\omega)t} = e^{-at} (k_1 e^{j\omega t} + k_2 e^{-j\omega t})$$

This equation can be reduced, as before, to the form

$$i_t = I_m e^{-at} \sin(\omega t + \phi) \quad \dots \text{ (iv)}$$

where  $I_m$  and  $\phi$  are constants as before. Equation (iv) represents damped transient oscillatory current as shown in Fig. 22.12 (b).

Fig. 22.12

The exponential term  $e^{-at}$  which accounts for the decay of oscillations, is called the decay or damping factor or merely **decrement**. It makes each current peak a definite fraction less than that preceding it. The logarithm to the Naperian base 'e' of the ratio of peaks one cycle apart in time is  $a/f = R/2fL$  and is referred to as **logarithmic decrement**. The frequency of damped oscillations is given by

$$f = \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}} \text{ and is called the natural frequency of the circuit}$$

$$\text{If } \frac{R^2}{4L^2} < \frac{1}{LC}, \text{ then } f = \frac{1}{2\pi\sqrt{LC}}$$

**Case 3. High-loss Circuit:**  $\frac{R^2}{4L^2} > \frac{1}{LC}$  i.e. **overdamped**

In this case,  $\lambda_1$  and  $\lambda_2$  will be pure numbers.

$$\lambda_1 = -\frac{R}{2L} + \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}} = -a + \gamma \text{ and } \lambda_2 = -a - \gamma$$

$$\therefore i_t = k_1 e^{(-a+\gamma)t} + k_2 e^{(-a-\gamma)t} = e^{-at} (k_1 e^{\gamma t} + k_2 e^{-\gamma t})$$

$$\text{Now } e^{\gamma t} = \sinh \gamma t + \cosh \gamma t$$

$$\text{and } e^{-\gamma t} = \cosh \gamma t - \sinh \gamma t$$

$$\therefore i_t = e^{-at} \{(k_1 + k_2) \cosh \gamma t + (k_1 - k_2) \sinh \gamma t\}$$

$$\text{or } i_t = e^{-at} (A \cosh \gamma t + B \sinh \gamma t)$$

A typical curve of this equation is shown in Fig. 22.12(c)

**Case 4.**  $\frac{R^2}{4L^2} = \frac{1}{LC}$  *i.e. Critical Damping*

In this case,  $\lambda_1 = \lambda_2 = -\frac{R}{2L}$

Hence, equation (iii) is reduced to

$$i_t = (k_1 + k_2 t)e^{-\frac{R}{2L}t} \text{ or } i_t = (k_1 + k_2 t)e^{-at}$$

It is a case of critical damping because current is reduced to almost zero in the shortest possible time. The above equation has been plotted in Fig. 22.12 (d).

Hence, we can summarize as follows:

1. Transient current is an undamped sine wave if  $R = 0$
2. Transient current is non-oscillatory if  $R < 2\sqrt{L/C}$
3. Transient current is non-oscillatory if  $R \geq 2\sqrt{L/C}$
4. Critical damping occurs if  $R = 2\sqrt{L/C}$

**Example 22.9.** A  $5\text{-}\mu\text{F}$  capacitor is discharged suddenly through a coil having an inductance of  $2\text{H}$  and a resistance of  $200\ \Omega$ . The capacitor is initially charged to a voltage of  $10\text{ V}$ . Find

(a) an expression for the current

(b) the additional resistance required to give critical damping.

**Solution.** Since there is no battery or generator in the circuit (Fig. 22.13), the steady-state current must be zero. It means that resultant current is simply the transient current.

Fig. 22.13

$$\begin{aligned} \text{Value of } 2\sqrt{L/C} &= 2\sqrt{2/5 \times 10^{-6}} \\ &= 1265\ \Omega \end{aligned}$$

Since  $R < 2\sqrt{L/C}$ , the circuit is originally oscillatory.

(a) the expression for the transient current, therefore, is

$$i_t = I_m e^{-at} \sin(\omega t + \phi)$$

where  $a = R/2L = 200/2 \times 2 = 50$

$$\sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}} = \sqrt{100,000 - 2500} = 312.3 \text{ rad/s}$$

$$\therefore i_t = I_m e^{-50t} \sin(312.3t + \phi) = i \quad \dots (i)$$

Two initial conditions are known from which  $I_m$  and  $\phi$  can be found (a) at  $t = 0$ ;  $i = 0$  and (b) at  $t = 0$ ;  $v_c = 10$  V. Applying condition (a) to Eq. (i), we get

$$0 = I_m \sin \phi, \text{ hence } \phi = 0 \quad \therefore i = I_m e^{-50t} \sin 312.3t \quad \dots (ii)$$

Now, at  $t = 0$ , the voltage across the inductance must be 10 V because the current in the resistance is zero.

$$\text{i.e. } (L di / dt)_{t=0} = 10 \text{ V} \therefore (di / dt)_{t=0} = 10 / L = 5 \text{ A/s} \quad \dots (iii)$$

Now, from equation (ii), we have

$$\frac{di}{dt} = -50 I_m e^{-50t} \sin 312.3t + 312.3 I_m e^{-50t} \cos 312.3t \quad \dots (iv)$$

Putting  $t = 0$ , it becomes  $(di / dt)_{t=0} = 312.3 I_m$

From equation (iii), we have

$$312.3 I_m = 5 \quad \therefore I_m = 5 / 312.3 = 0.016 \text{ A}$$

Hence, the general expression for the current becomes

$$i = 0.016 e^{-50t} \sin 312.3t$$

It is roughly plotted (the first few cycles only) in Fig. 22.13 (b).

(b) Critical damping is achieved when  $R = 2\sqrt{L/C}$

$$\therefore R = 2\sqrt{2/5 \times 10^{-6}} = 1265 \Omega$$

$$\therefore \text{Additional resistance reqd.} = 1265 - 200 = 1065 \Omega$$

**Example 22.10.** A damped oscillation has the equation  $i = 50e^{-10t} \sin 628t$ . Find the number of oscillations which occurs before the amplitude of the oscillations decays to 1/10th of its undamped value.

**Solution.** Undamped amplitude = 50 A

$$1/10\text{th amplitude} = (1/10) \times 50 = 5 \text{ A}$$

Let the time required for this decay be  $t$ . Now, the decay of the peak of the oscillations is given by the term  $50e^{-10t}$

$$\therefore 5 = 50e_1^{-10t} \therefore e_1^{10t_1} = 10 \text{ or } 10t_1 = \log h^{10} = 2.3 \log_{10}^{10} = 2.3$$

$$\therefore t_1 = 0.23 \text{ second}$$

$$\text{Frequency of oscillations} = 628 / 2\pi = 100 \text{ Hz.}$$

Hence, the number of oscillations which occur before the amplitude falls to 1/10th of its undamped value is =  $0.23 \times 100 = 23$

**Example 22.11.** If, in Fig. 22.14, a break occurs at a point marked X, what would be the voltage across the break? It may be assumed that prior to the break, steady conditions existed in the circuit.

**Solution.** Steady-state current through the inductance =  $120/60 = 2 \text{ A}$

Energy stored in the inductor prior to the break

$$= \frac{1}{2} LI^2 = \frac{1}{2} \times 12 \times 10^{-3} \times 4 = 24 \times 10^{-3} \text{ J}$$

Energy initially stored in the capacitor

$$= \frac{1}{2} CV^2 = \frac{1}{2} \times 10^{-8} \times 120^2 = 72 \times 10^{-6} \text{ J} = 0\text{-practically}$$

Fig. 22.14

When the break occurs, the energy stored in the inductor is transferred to the capacitor. If loss of energy during first transfer is neglected, then maximum energy stored in the capacitor is

$$= 20 \times 10^{-3} \text{ J} \therefore \frac{1}{2} CV_m^2 = 24 \times 10^{-3}$$

$$\therefore V_m = \sqrt{2 \times 24 \times 10^{-3} \times 10^8} = 2,190 \text{ V}$$

Maximum voltage across the break is = 2190 + 120 = 2310 V

The voltage would be oscillatory because the energy alternates between the inductor and capacitor.

Frequency of voltage oscillation is

$$f = 1/2\pi\sqrt{LC} = 10^5 / 2\pi \times \sqrt{1.2} = 14,530 \text{ Hz}$$

Decay or damping factor =  $e^{-at}$  Art. 22.10, Case 2

Here,  $a = R/2L = 60/2 \times 12 \times 10^{-3} = 2500$   $\therefore$  damping factor =  $e^{-2500t}$

Hence, voltage across the break is

$$= 120 + 2190 e^{-2500t} \sin 2\pi \times 14,500t = \mathbf{120 + 2190 e^{-2500t} \sin 91,290t}$$

### Tutorial Problem No. 22.1

1. Deduce an expression for the growth of current in an inductive circuit.

A 15-H inductance coil of 10  $\Omega$  resistance is suddenly connected to a 20 V d.c. supply. Calculate:

- the initial rate of change of current
- the current after 2 second
- the rate of change of current after 2 second
- the energy stored in the magnetic field in this time
- the energy lost as heat in this time
- the time constant.

3. A circuit consisting of a 20  $\Omega$  resistor, 20 mH inductor and a 100  $\mu\text{F}$  capacitor in series is connected to a 200 V, d.c. supply. The capacitor is initially uncharged. Determine the equation relating the instantaneous current to the time and find the maximum instantaneous current.

**[( $20 e^{-500t} \sin 500t$ ) A; 6.44 A]**

4. Find an expression for the value of current at any instant after a sinusoidal voltage of amplitude 600 V at 50 Hz is applied to a series circuit of resistance 10  $\Omega$  and inductance 0.1 H, assuming that voltage is zero at the instant of switching. Also, find the value of transient current at  $t = 0.02$  second.

**[- 15.14 A; 2.17 A] (*Electric Circuits and Fields, Gujarat Univ.*)**

5. A 40  $\Omega$  resistor and a 50  $\mu\text{F}$  capacitor are connected in series and supplied with an alternating voltage  $v = 283 \sin 314t$ . The supply is switched on at the instant when the voltage is zero. Determine the expression for the instantaneous current at time  $t$ .

**[-  $3.18 e^{-500t} + 3.76 \sin(314t + 57^\circ 50')$ ]**

6. A d.c. voltage of 100 V is suddenly applied to a circuit consisting of a 100  $\Omega$  resistor, a 0.1 H inductor and a 100  $\mu\text{F}$  capacitor in series. The capacitor is initially uncharged. Obtain the equation which shows how the capacitor voltage varies with time.

**[ $100 - 115.3 e^{-500t} \sin(866t + \pi/3 \text{ V})$ ]**

7. The voltage  $v = 200 \sin 314t$  is suddenly applied at  $t = 0$  to a circuit consisting of a  $10 \Omega$  resistor in series with a  $0.1 \text{ H}$  inductor. Deduce an equation showing how the current varies with time.

$$[5.78 e^{-100t} + 6.06 \sin(314t - 72^\circ 20')]$$

8. A  $20 \Omega$  resistor, a  $0.01 \text{ H}$  inductor and a  $100 \mu\text{F}$  capacitor are connected in series. A d.c. voltage of  $100 \text{ V}$  is suddenly applied to the circuit. Obtain the equation showing how the current through the circuit varies with time. Find the maximum current and the time at which it occurs.

$$[10^4 e^{-100t}; 3.67 \text{ A}; 0.001 \text{ second}]$$

9. A  $4 \mu\text{F}$  capacitor is initially charged to  $300 \text{ V}$ . It is discharged through a  $100 \text{ mH}$  inductance and a resistor in series:

- find the frequency of the discharge if the resistance is zero.
- how many cycles at the above frequency will occur before the discharge oscillation decays to  $1/10$  of its initial value if the resistance is  $1 \Omega$ .
- find the value of the resistance which would just prevent oscillations.

$$[(a) 796 \text{ Hz} (b) 36.6 (c) 100 \Omega]$$

### OBJECTIVE TESTS – 22

- Transient disturbance is produced in a circuit whenever
  - it is suddenly connected or disconnected from the supply
  - it is shorted
  - its applied voltage is changed suddenly
  - all of the above.
- There are no transients in pure resistive circuits because they
  - offer high resistance
  - obey Ohm's law
  - have no stored energy
  - are linear circuits.
- Transient currents in electrical circuit are associated with
  - inductors
  - capacitors
  - resistors
  - both (a) and (b).
- The transients which are produced due to sudden but energetic changes from one steady state of a circuit to another are called ..... transients.
 

(a) initiation	(b) transition
(c) relaxation	(d) subsidence
- In an  $R-L$  circuit connected to an alternating sinusoidal voltage, size of transient current primarily depends on
  - the instant in the voltage cycle at which circuit is closed
  - the peak value of steady-state current
  - the circuit impedance
  - the voltage frequency.
- Double-energy transients are produced in circuits consisting of
  - two or more resistors
  - resistance and inductance
  - resistance and capacitance
  - resistance, inductance and capacitance.
- The transient current in a loss-free  $L-C$  circuit when excited from an ac source is  $a/$  an ..... sine wave.
 

(a) over damped	(b) undamped
(c) under damped	(d) critically damped.
- Transient current in an  $R-L-C$  circuit is oscillatory when
 

(a) $R = 0$	(b) $R > 2\sqrt{L/C}$
(c) $R < 2\sqrt{L/C}$	(d) $R = 2\sqrt{L/C}$

### ANSWERS

1. (d) 2. (c) 3. (d) 4. (b) 5. (a) 6. (d) 7. (b) 8. (c)

## CHAPTER 23

**Learning Objectives**

- Introduction
- The Positive-sequence Components
- The Negative-sequence Components
- The Zero-sequence Components
- Graphical Composition of Sequence Vectors
- Evaluation of  $V_{A1}$  or  $V_1$
- Evaluation of  $V_{A2}$  or  $V_2$
- Evaluation  $V_{A0}$  or  $V_0$
- Zero Sequence Components of Current and Voltage
- Unbalanced Star Load form Unbalanced Three-phase Three-Wire System
- Unbalanced Star Load Supplied from Balanced Three-phase Three-wire System
- Measurement of Symmetrical Components of Circuits
- Measurement of Positive and Negative-sequence Voltages
- Measurement of Zero-sequence Component of Voltage

**SYMMETRICAL COMPONENTS**

Any unbalanced 3-phase system of vectors (whether representing voltages or currents) can be resolved into three balanced systems of vectors which are called its 'symmetrical components'

### 23.1. Introduction

The method of symmetrical components was first proposed by C.L. Fortescue and has been found very useful in solving unbalanced polyphase circuits, for analytical determination of the

Fig. 23.1

Fig. 23.2

performance of polyphase electrical machinery when operated from a system of unbalanced voltages and for calculation of currents resulting from unbalanced faults. According to Fortescue's theorem, any unbalanced 3-phase system of vectors (whether representing voltages or currents) can be resolved into three **balanced** systems of vectors which are called its '**symmetrical components**'. In Fig. 23.1 (a) is shown a set of three unbalanced voltage vectors  $V_A$ ,  $V_B$  and  $V_C$  having phase sequence  $A \rightarrow B \rightarrow C$ . These can be regarded as made up of the following symmetrical components :-

(i) A balanced system of 3-phase vectors  $V_{A1}$ ,  $V_{B1}$  and  $V_{C1}$  having the phase sequence  $A \rightarrow B \rightarrow C$  as the original set of three unbalanced vectors. These vectors constitute the positive-sequence components [Fig. 23.1 (b)].

(ii) A balanced system of 3-phase vectors  $V_{A2}$ ,  $V_{B2}$  and  $V_{C2}$  having phase sequence  $A \rightarrow C \rightarrow B$  which is opposite to that of the original unbalanced vectors. These vectors constitute the negative-sequence components [Fig. 23.1 (c)].

(iii) A system of three vectors  $V_{A0}$ ,  $V_{B0}$  and  $V_{C0}$  which are equal in magnitude and are in phase with each other *i.e.*  $V_{A0} = V_{B0} = V_{C0}$ . These three co-phasal vectors form a uniphase system and are known as zero-sequence components [Fig. 23.1(d).]

Hence, it means that an unbalanced 3-phase system of voltages or current can be regarded as due to the superposition of two symmetrical 3-phase systems having opposite phase sequences and a system of zero phase sequence *i.e.* ordinary single-phase current or voltage system. In Fig. 23.2, each of the original vectors has been

3-phase monitor continuously monitors 3-phase wave lines for abnormal conditions

reconstructed by the vector addition of its positive-sequence, negative - sequence and zero-sequence components. It is seen that

$$V_A = \overset{-ve}{V_{A1}} + \overset{-ve}{V_{A2}} + \overset{zero}{V_{A0}} \quad \dots (i)$$

$$V_B = V_{B1} + V_{B2} + V_{B0} \quad \dots (ii)$$

$$V_C = V_{C1} + V_{C2} + V_{C0} \quad \dots (iii)$$

### 23.2. The Positive - sequence Components

As seen from above, the positive-sequence components have been designated as  $V_{A1}$ ,  $V_{B1}$  and  $V_{C1}$ . The subscript 1 is meant to indicate that the vector belongs to the positive-sequence system. The letter refers to the original vector of which the positive-sequence vector is a component part.

These positive-sequence vectors are completely determined when the magnitude and phase of any one of these is known. Usually, these vectors are related to each other with the help of the operator  $a$  (for details, please refer to Art. 12.11). As seen from Fig. 23.1 (b).

$$\mathbf{V}_{A1} = V_{A1}; \mathbf{V}_{B1} = a^2 V_{A1} = V_{A1} \angle -120^\circ; \mathbf{V}_{C1} = a V_{A1} = V_{A1} \angle 120^\circ$$

### 23.3. The Negative - sequence Components

This system has a phase sequence of  $A \rightarrow C \rightarrow B$ . Since this system is also balanced, it is completely determined when the magnitude and phase of one of the vectors becomes known. The suffix 2 indicates that the vector belongs to the negative-sequence system. Obviously, as seen from Fig. From 23.1 (c).

$$\mathbf{V}_{A2} = V_{A2}; \mathbf{V}_{B2} = a V_{A2} = V_{A2} \angle 120^\circ; \mathbf{V}_{C2} = a^2 V_{A2} = V_{A2} \angle -120^\circ$$

### 23.4. The Zero - sequence Components

These three vectors are equal in magnitude and phase and hence form what is known as uniphase system. They are designated as  $V_{A0}$ ,  $V_{B0}$  and  $V_{C0}$ . Since these are identical in magnitude

$$\therefore V_{A0} = V_{B0} = V_{C0}$$

### 23.5. Graphical Composition of Sequence Vectors

Fig. 23.2 Shows how the original vector  $V_A$  has been obtained by the addition of  $V_{A1}$ ,  $V_{A2}$  and  $V_{A0}$ . The same applies to other vectors  $V_B$  and  $V_C$ .

For simplicity, let us write  $V_{A1}$  as  $V_1$ ,  $V_{A2}$  as  $V_2$  and  $V_{A0}$  as  $V_0$ . Then

$$\mathbf{V}_A = \mathbf{V}_1 + \mathbf{V}_2 + \mathbf{V}_0 \quad \dots (iv)$$

$$\mathbf{V}_B = a^2 \mathbf{V}_1 + a \mathbf{V}_2 + \mathbf{V}_0 \quad \dots (v)$$

$$\mathbf{V}_C = a \mathbf{V}_1 + a^2 \mathbf{V}_2 + \mathbf{V}_0 \quad \dots (vi)$$

### 23.6. Evaluation of $V_{A1}$ or $V_1$

The procedure for evaluating  $V_1$  is as follows :

Multiplying (v) by  $a$  and (vi) by  $a^2$ , we get

$$a \mathbf{V}_B = a^3 \mathbf{V}_1 + a^2 \mathbf{V}_2 + a \mathbf{V}_0; \quad a^2 \mathbf{V}_C = a^3 \mathbf{V}_1 + a^4 \mathbf{V}_2 + a^2 \mathbf{V}_0$$

Now  $a^3 = 1$  and  $a^4 = a$ , hence

$$a\mathbf{V}_B = \mathbf{V}_1 + a^2\mathbf{V}_2 + a\mathbf{V}_0 \quad \dots \text{(vii)}$$

$$a^2\mathbf{V}_C = \mathbf{V}_1 + a\mathbf{V}_2 + a^2\mathbf{V}_0 \quad \dots \text{(viii)}$$

Adding (iv), (vii) and (viii), we get

$$\mathbf{V}_A + a\mathbf{V}_B + a^2\mathbf{V}_C = 3\mathbf{V}_1 + \mathbf{V}_2(1 + a + a^2) + \mathbf{V}_0(1 + a + a^2) = 3\mathbf{V}_1$$

$$\therefore \mathbf{V}_1 = \frac{1}{3}(\mathbf{V}_A + a\mathbf{V}_B + a^2\mathbf{V}_C) = \frac{1}{3}(\mathbf{V}_A + \mathbf{V}_B \angle 120^\circ + \mathbf{V}_C \angle -210^\circ)$$

$$\frac{1}{3} V_A \quad V_B \quad \frac{1}{2} j \frac{\sqrt{3}}{2} \quad V_C \quad \frac{1}{2} j \frac{\sqrt{3}}{2}$$

This shows that, geometrically speaking,  $V_1$  is a vector one-third as large as the vector obtained by the vector addition of the three original vectors  $V_A$ ,  $V_B \angle 120^\circ$  and  $V_C \angle -120^\circ$ .

### 23.7. Evaluation of $V_{A2}$ or $V_2$

Multiplying (vi) by  $a$  and (v) by  $a^2$  and adding them to (iv) we get

$$a\mathbf{V}_C = a^2\mathbf{V}_1 + a^3\mathbf{V}_2 + a\mathbf{V}_0; a^2\mathbf{V}_B = a^4\mathbf{V}_1 + a^3\mathbf{V}_2 + a^2\mathbf{V}_0$$

$$\mathbf{V}_A + a^2\mathbf{V}_B + a\mathbf{V}_C = \mathbf{V}_1(1 + a + a^2) + 3\mathbf{V}_2 + \mathbf{V}_0(1 + a + a^2) = 3\mathbf{V}_2 \quad \text{Now, } 1 + a + a^2 = 0$$

$$\therefore \mathbf{V}_2 = \frac{1}{3}(\mathbf{V}_A + a^2\mathbf{V}_B + a\mathbf{V}_C) = \frac{1}{3}(\mathbf{V}_A + \mathbf{V}_B \angle -120^\circ + \mathbf{V}_C \angle 120^\circ)$$

$$= \frac{1}{3} \left[ \mathbf{V}_A + \mathbf{V}_B \left( -\frac{1}{2} - j \frac{\sqrt{3}}{2} \right) + \mathbf{V}_C \left( -\frac{1}{2} + j \frac{\sqrt{3}}{2} \right) \right]$$

### 23.8. Evaluation of $V_{A0}$ or $V_0$

Adding (iv), (v) and (vi), we get  $\mathbf{V}_A + \mathbf{V}_B + \mathbf{V}_C = \mathbf{V}_1(1 + a + a^2) + \mathbf{V}_2(1 + a + a^2) + 3\mathbf{V}_0 = 3\mathbf{V}_0$

$$\therefore \mathbf{V}_0 = \frac{1}{3}(\mathbf{V}_A + \mathbf{V}_B + \mathbf{V}_C)$$

It shows that  $V_0$  is simply a vector one third as large as the vector obtained by adding the original vectors  $V_A$ ,  $V_B$  and  $V_C$ .

To summarize the above results, we have

$$\text{(i) } \mathbf{V}_1 = \frac{1}{3}(\mathbf{V}_A + a\mathbf{V}_B + a^2\mathbf{V}_C) \quad \text{(ii) } \mathbf{V}_2 = \frac{1}{3}(\mathbf{V}_A + a^2\mathbf{V}_B + a\mathbf{V}_C)$$

$$\text{(iii) } \mathbf{V}_0 = \frac{1}{3}(\mathbf{V}_A + \mathbf{V}_B + \mathbf{V}_C)$$

**Note.** An unbalanced system of 3-phase currents can also be likewise resolved into its symmetrical components. Hence

$$\mathbf{I}_A = \mathbf{I}_1 + \mathbf{I}_2 + \mathbf{I}_0; \mathbf{I}_B = a^2\mathbf{I}_1 + a\mathbf{I}_2 + \mathbf{I}_0; \mathbf{I}_C = a\mathbf{I}_1 + a^2\mathbf{I}_2 + \mathbf{I}_0$$

$$\text{Also, as before } \mathbf{I}_1 = \frac{1}{3}(\mathbf{I}_A + a\mathbf{I}_B + a^2\mathbf{I}_C); \mathbf{I}_2 = \frac{1}{3}(\mathbf{I}_A + a^2\mathbf{I}_B + a\mathbf{I}_C); \mathbf{I}_0 = \frac{1}{3}(\mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C) \quad \dots \text{(ix)}$$

It shows that  $I_0$  is one-third of the neutral or earth-return current and is zero for an unearthed 3-wire system. It is seen from (ix) above that  $I_0$  is zero if the vector sum of the original current vectors is zero. This fact can be used with advantage in making numerical calculations because the original system of vectors can then be reduced to two balanced 3-phase systems having opposite phase sequences.

**Example 23.1.** Find out the positive, negative and zero-phase sequence components of the following set of three unbalanced voltage vectors:

$$V_A = 10\angle 30^\circ; V_B = 30\angle -60^\circ; V_C = 15\angle 145^\circ$$

Indicate on an approximate diagram how the original vectors and their different sequence components are located. **(Principles of Elect. Engg. – I, Jadavpur Univ.)**

**Solution. (i) Positive-sequence vectors**

As seen from Art. 23.6

$$\begin{aligned} \mathbf{V}_1 &= \frac{1}{3}(\mathbf{V}_A \ a\mathbf{V}_B \ a^2\mathbf{V}_C) = \frac{1}{3}(10 \ 30 \ a.30 \ 60 \ a^2.15 \ 145) \\ &= \frac{1}{3}(10\angle 30^\circ + 30\angle 60^\circ + 15\angle 25^\circ) = 12.42 + j12.43 = 17.6\angle 45^\circ \end{aligned}$$

$$\therefore \mathbf{V}_{A1} \ 17.6 \ 45^\circ; \mathbf{V}_{B1} \ 17.6 \ 45^\circ \quad 120^\circ \ 17.6 \ 75^\circ$$

$$\mathbf{V}_{C1} \ 17.6 \ 45^\circ \quad 120^\circ \ 17.6 \ 165^\circ$$

These are shown in Fig. 23.1 (b)

**(ii) Negative-sequence vectors**

As seen from Art. 23.7,

$$\begin{aligned} \mathbf{V}_2 &= \frac{1}{3}(\mathbf{V}_A \ a^2\mathbf{V}_B \ a\mathbf{V}_C) = \frac{1}{3}(10 \ 30 \ a^2.30 \ 60 \ a.15 \ 145) \\ &= \frac{1}{3}(10\angle 30^\circ + 30\angle -180^\circ + 15\angle 265^\circ) = -7.55 - j3.32 = 8.24\angle -156.2^\circ \end{aligned}$$

$$\mathbf{V}_{A2} \ 8.24 \ 156.2^\circ; \mathbf{V}_{B2} \ 8.24 \ 156.2^\circ \quad 120^\circ \ 8.24 \ 36.2^\circ$$

$$\mathbf{V}_{C2} \ 8.24 \ 156.2^\circ \quad 120^\circ \ 8.24 \ 276.2^\circ$$

These vectors are shown in Fig. 23.1 (c)

**(iii) Zero sequence vectors**

$$\begin{aligned} \mathbf{V}_0 &= \frac{1}{3}(\mathbf{V}_A + \mathbf{V}_B + \mathbf{V}_C) \\ &= \frac{1}{3}(10\angle 30^\circ + 30\angle -60^\circ + 15\angle 145^\circ) = 3.8 - j4.12 = 5.6\angle -47.4^\circ \end{aligned}$$

These vectors are shown in Fig. 23.1 (d).

**Example 23.2.** Explain how an unsymmetrical system of 3-phase currents can be resolved into 3 symmetrical component systems.

Determine the values of the symmetrical components of a system of currents

$$I_R = 0 + j120A; I_Y = 50 - j100A; I_B = -100 - j50A$$

Phase sequence is RYB.

**(Elect. Engg.-I Bombay, Univ.)**

**Solution.**  $\mathbf{I}_R \ 0 \ j120 \ 120 \ 90$

$$\mathbf{I}_Y \ 50 \ j100 \ 111.8 \ 63.5^\circ; \mathbf{I}_B \ 100 \ j50 \ 111.8 \ 153.5$$

**(i) Positive-sequence Components**

$$\mathbf{I}_1 = \frac{1}{3}(\mathbf{I}_R \ a\mathbf{I}_Y \ a^2\mathbf{I}_B) = \frac{1}{3}(0 \ j120) + \frac{1}{2}j\frac{\sqrt{3}}{2}(50 \ j100) + \frac{1}{2}j\frac{\sqrt{3}}{2}(100 \ j50)$$

$$= 22.8 + j108.3 = 110.7 \angle 78.1^\circ \therefore \mathbf{I}_{R1} \quad 110.7 \quad 78.1; \mathbf{I}_{Y1} \quad 110.7 \quad 41.9; \mathbf{I}_{B1} \quad 110.7 \quad 198.1$$

(ii) Negative-sequence components

$$\mathbf{I}_2 = \frac{1}{3}(\mathbf{I}_R - a^2\mathbf{I}_Y - a\mathbf{I}_B) = \frac{1}{3}(18.3 - j65.1 - 6.1 - j21.7 - 22.5 - 105.7)$$

$$\therefore \mathbf{I}_{R2} \quad 22.5 \quad 105.7; \mathbf{I}_{Y2} \quad 22.5 \quad 225; \mathbf{I}_{B2} \quad 22.5 \quad 14.3$$

(iii) Zero-sequence component

$$\mathbf{I}_0 = \frac{1}{3}(\mathbf{I}_R + \mathbf{I}_Y + \mathbf{I}_B) = \frac{1}{3}[(0 - j120) + (50 - j100) + (100 - j50)] = 16.7 - j10$$

As a check, it may be found that

$$\mathbf{I}_R = \mathbf{I}_{R1} + \mathbf{I}_{R2} + \mathbf{I}_0; \mathbf{I}_Y = \mathbf{I}_{Y1} + \mathbf{I}_{Y2} + \mathbf{I}_0; \mathbf{I}_B = \mathbf{I}_{B1} + \mathbf{I}_{B2} + \mathbf{I}_0$$

**Example 23.3.** In a 3-phase, 4-wire system, the currents in the R, Y and B lines under abnormal conditions of loading were as follows:

$$I_R = 100 \angle 30^\circ; I_Y = 50 \angle 300^\circ; I_B = 30 \angle 180^\circ$$

Calculate the positive, negative and zero-phase sequence currents in the R-line and the return current in the neutral conductor.

**Solution.** (i) The positive-sequence components of current in the R-line is

$$\mathbf{I}_1 = \frac{1}{3}(\mathbf{I}_R + a\mathbf{I}_Y + a^2\mathbf{I}_B)$$

$$\text{Now } \mathbf{I}_R = 100 \angle 30^\circ = 50(\sqrt{3} - j)$$

$$\mathbf{I}_Y = 50 \angle 300^\circ = 50 \left( \frac{1}{2} + j\frac{\sqrt{3}}{2} \right) = 25(1 + j\sqrt{3})$$

$$\mathbf{I}_B = 30 \angle 180^\circ = (-30 + j0)$$

$$\mathbf{I}_1 = \frac{1}{3} [50(\sqrt{3} - j) + 25(1 + j\sqrt{3}) - 30] = \frac{1}{2} \left( \frac{\sqrt{3}}{2} - j \right) + (30) \left( \frac{1}{2} + j\frac{\sqrt{3}}{2} \right) = 58 - j48.4$$

(ii) The negative-sequence components of the current in the R-line is

$$\mathbf{I}_2 = \frac{1}{3}(\mathbf{I}_R + a^2\mathbf{I}_Y + a\mathbf{I}_B)$$

$$= \frac{1}{3} [50(\sqrt{3} - j) + 25(1 - j\sqrt{3}) - 30] = \frac{1}{2} \left( \frac{\sqrt{3}}{2} - j \right) - (30) \left( \frac{1}{2} + j\frac{\sqrt{3}}{2} \right) = 18.9 - j24.9$$

(iii) The zero-sequence component of current in the R-line is

$$\mathbf{I}_0 = \frac{1}{3}(\mathbf{I}_R + \mathbf{I}_Y + \mathbf{I}_B) = \frac{1}{3}[50(\sqrt{3} - j) + 25(1 + j\sqrt{3}) - 30] = 27.2 - j4.7$$

The neutral current is

$$\mathbf{I}_N = \mathbf{I}_R + \mathbf{I}_Y + \mathbf{I}_B = 3 \mathbf{I}_0 = 3(27.2 - j4.7) = 81.6 - j14.1$$

**Example 23.4.** A 3-phase, 4-wire system supplies loads which are unequally distributed on the three phases. An analysis of the currents flowing in the direction of the loads in the R, Y and B lines shows that in the R-line, the positive phase sequence current is  $200 \angle 0^\circ$  A and the

negative phase sequence current is  $100 \angle 60^\circ$ . The total observed current flowing back to the supply in the neutral conductor is  $300 \angle 300^\circ$  A. Calculate the currents in phase and magnitude in the three lines.

Assuming that the 3-phase supply voltages are symmetrical and that the power factor of the load on the R-phase is  $\sqrt{3}/2$  leading, determine the power factor of the loads on the two other phases.

**Solution.** It is given that in R-phase [Fig. 23.3 (a)]

$$\mathbf{I}_{R1} = 200 \angle 0^\circ = (200 + j0) \text{ A}; \mathbf{I}_{R2} = 100 \angle 60^\circ = (50 + j86.6) \text{ A}$$

$$\mathbf{I}_{R0} = \frac{1}{3} \mathbf{I}_N = (300/3) \angle 300^\circ = (50 - j86.6) \text{ A}$$

$$\mathbf{I}_R \quad \mathbf{I}_{R1} \quad \mathbf{I}_{R2} \quad \mathbf{I}_{R0} \quad (200 \quad j0) \quad (50 \quad j86.6) \quad (50 \quad j86.6) \quad (300 \quad j0) \quad 300 \quad 0$$

Similarly, as seen from Fig. 23.3 (b) for the Y-phase

$$\begin{aligned} \mathbf{I}_Y &= \mathbf{I}_{Y1} + \mathbf{I}_{Y2} + \mathbf{I}_{Y0} = a^2 \mathbf{I}_{R1} + a \mathbf{I}_{R2} + \mathbf{I}_{R0} \\ &= 200 \angle 0^\circ - 120^\circ + 100 \angle 60^\circ + 120^\circ \\ &\quad + 100 \angle 300^\circ = -100 - j173.2 - 100 + 50 - j86.6 = -150 - j259.8 = 300 \angle 240^\circ \text{ A} \end{aligned}$$

Similarly, as seen from Fig. 23-3 (c) for the B-phase

$$\mathbf{I}_B \quad \mathbf{I}_{B1} \quad \mathbf{I}_{B2} \quad \mathbf{I}_{B0} \quad a \mathbf{I}_{R1} \quad a^2 \mathbf{I}_{R2} \quad \mathbf{I}_{R0} \quad 200 \quad 0 \quad 120 \quad 100 \quad 60 \quad 120 \quad 100 \quad 300 \quad 0$$

Fig. 23.3

Since the power factor of the  $R$ -phase is  $\sqrt{3}/2$  leading, the current  $I_R$  leads the voltage  $V_R$  by  $30^\circ$  [Fig. 23.3(d)]

(d) Now, phase angle of  $I_Y$  is  $240^\circ$  relative to  $I_R$  so that  $I_Y$  leads its voltage  $V_Y$  by  $30^\circ$ . Hence, power factor of  $Y$  phase is also  $\sqrt{3}/2$  leading. The power factor of  $B$  line is indeterminate because the current in this line is zero.

**Example 23.5.** Prove that in a 3-phase system if  $V_1$ ,  $V_2$  and  $V_3$  are the three balanced voltages whose phasor sum is zero, the positive and negative sequence components can be expressed as

$$V_{1p} = \left\{ \frac{1}{\sqrt{3}} (V_1 + V_2 \angle 60^\circ) \right\} \angle 30^\circ; V_{1N} = \left\{ \frac{1}{\sqrt{3}} (V_1 + V_2 \angle -60^\circ) \right\} \angle -30^\circ$$

Phase sequence is 1-2-3.

A system of 3-phase currents is given as  $I_1 = 10 \angle 180^\circ$ ,  $I_2 = 14.14 \angle -45^\circ$  and  $I_3 = 10 \angle 90^\circ$ . Determine phasor expression for the sequence components of these currents. Phase sequence is 1-2-3. **(Elect. Engg-I, Bombay Univ.)**

**Solution.** As seen from Art. 23.6

$$\mathbf{V}_{1P} = \frac{1}{3}(\mathbf{V}_1 + a\mathbf{V}_2 + a^2\mathbf{V}_3); \text{ Now, } \mathbf{V}_1 + \mathbf{V}_2 + \mathbf{V}_3 = 0 \therefore \mathbf{V}_3 = -(\mathbf{V}_1 + \mathbf{V}_2)$$

$$\mathbf{V}_{1P} = \frac{1}{3}[\mathbf{V}_1 + a\mathbf{V}_2 - a^2(\mathbf{V}_1 + \mathbf{V}_2)] = \frac{1}{3}[\mathbf{V}_1(1 - a^2) + \mathbf{V}_2(a - a^2)]$$

$$\text{Now, } 1 - a^2 = \frac{2}{3} + j\frac{\sqrt{3}}{2} \text{ and } a - a^2 = j\sqrt{3}$$

$$\therefore \mathbf{V}_{1P} = \frac{1}{3} \mathbf{V}_1 \left[ \frac{2}{3} + j\frac{\sqrt{3}}{2} \right] + \frac{j\sqrt{3}}{3} \mathbf{V}_2 = \frac{1}{\sqrt{3}} \mathbf{V}_1 \left[ \frac{\sqrt{3}}{2} + j\frac{1}{2} \right] + j\mathbf{V}_2$$

$$= \frac{1}{\sqrt{3}} [\mathbf{V}_1 \angle 30^\circ + \mathbf{V}_2 \angle 90^\circ] = \left[ \frac{1}{\sqrt{3}} (\mathbf{V}_1 + \mathbf{V}_2 \angle 60^\circ) \right] \angle 30^\circ$$

Similarly, the negative-sequence component is given by

$$\mathbf{V}_{1N} = \frac{1}{3}(\mathbf{V}_1 + a^2\mathbf{V}_2 + a\mathbf{V}_3) = \frac{1}{3}[\mathbf{V}_1 + a^2\mathbf{V}_2 - a(\mathbf{V}_1 + \mathbf{V}_2)] = \frac{1}{3}[\mathbf{V}_1(1 - a) + \mathbf{V}_2(a^2 - a)]$$

$$\text{Now, } a^2 - a = -j\sqrt{3}$$

$$\begin{aligned} \therefore \mathbf{V}_{1N} &= \frac{1}{3} \left[ \mathbf{V}_1 \left( \frac{3}{2} - j\frac{\sqrt{3}}{2} \right) - j\sqrt{3}\mathbf{V}_2 \right] = \frac{1}{\sqrt{3}} \left[ \mathbf{V}_1 \left( \frac{\sqrt{3}}{2} - j\frac{1}{2} \right) - j\mathbf{V}_2 \right] \\ &= \frac{1}{\sqrt{3}} [\mathbf{V}_1 \angle -30^\circ + \mathbf{V}_2 \angle -90^\circ] = \left\{ \frac{1}{\sqrt{3}} (\mathbf{V}_1 + \mathbf{V}_2 \angle -60^\circ) \right\} \angle -30^\circ \end{aligned}$$

$$\text{Now } \mathbf{I}_1 = 10 \angle 180^\circ = -10 + j0; \mathbf{I}_2 = 14.14 \angle -45^\circ = 10 - j10$$

$$\mathbf{I}_3 = 10 \angle 90^\circ = j10$$

$$a\mathbf{I}_2 = 14.14 \cdot 75 \cdot 3.66 \cdot j13.66; a^2\mathbf{I}_2 = 14.14 \cdot 165 \cdot 13.66 \cdot j3.66$$

$$a\mathbf{I}_3 = 14.14 \cdot 21 \cdot 12.25 \cdot j7.07; a^2\mathbf{I}_3 = 14.14 \cdot 30 \cdot 12.25 \cdot j7.07$$

$$\mathbf{I}_{1P} = \frac{1}{3}(\mathbf{I}_1 + a\mathbf{I}_2 + a^2\mathbf{I}_3) = \frac{1}{3}(5.91 - j6.59) = 1.97 - j2.2$$

$$\mathbf{I}_{1N} = \frac{1}{3}(\mathbf{I}_1 + a^2\mathbf{I}_2 + a\mathbf{I}_3) = \frac{1}{3}(35.91 + j10.73) = 11.97 + j3.58$$

$$\mathbf{I}_{10} = \frac{1}{3}(\mathbf{I}_1 + \mathbf{I}_2 + \mathbf{I}_3) = 0$$

### Tutorial Problems No. 23.1

1. The following currents were recorded in the  $R$ ,  $Y$ , and  $B$  lines of a 3-phase system under abnormal conditions:

$$[\mathbf{I}_R = 300\angle 300^\circ \text{ A}; \mathbf{I}_Y = 500\angle 240^\circ \text{ A}; \mathbf{I}_B = 1,000\angle 60^\circ \text{ A}]$$

Calculate the values of the positive, negative and zero phase-sequence components.

$$[\mathbf{I}_1 = 536\angle -44^\circ 20' \text{ A}; \mathbf{I}_2 = 372\angle 171^\circ \text{ A}; \mathbf{I}_0 = 145\angle 23^\circ 20']$$

2. Determine the symmetrical components of the three currents  $I_0 = 10\angle 0^\circ$ ;  $\mathbf{I}_b = 100\angle 250^\circ$  and  $\mathbf{I}_c = 10\angle 110^\circ \text{ A}$

$$[\mathbf{I}_1 = (39.45 + j52.2) \text{ A}; \mathbf{I}_2 = (-20.24 + j22.98) \text{ A}; \mathbf{I}_0 = (-9.21 - j28.19) \text{ A}]$$

(*Elect. Meas & Measuring Instru., Madras Univ.*)

3. The three current vectors of a 3-phase, four-wire system have the following values;  $\mathbf{I}_A = 7 + j_0$ ,  $\mathbf{I}_B = -12 - j13$  and  $\mathbf{I}_C = -2 + j3$ . Find the symmetrical components. The phase sequence is  $A, B, C$

$$[\mathbf{I}_0 = -2.33 - j3.33; \mathbf{I}_{A1} = (27.75 - j3.67); \mathbf{I}_{B1} = (-17.05 - j22.22); \mathbf{I}_{C1} = (-10.7 + j25.9);$$

$$\mathbf{I}_{A2} = (0.25 + j13.67) \text{ A}; \mathbf{I}_{B2} = (-11.97 - j6.62) \text{ A}; \mathbf{I}_{C2} = (11.73 - j7.05) \text{ A}]$$

### 23.9. Zero-Sequence Components of Current and Voltage

Any circuit which allows the flow of positive-sequence currents will also allow the flow of negative-sequence currents because the two are similar. However, a fourth wire is necessary if zero-sequence components are to flow in the lines of the 3-phase system. It follows that the line currents of 3-phase 3-wire system can contain no zero sequence components whether it is delta - or star-connected. The zero sequence components of line-to-line voltages are non-existent regardless of the degree of imbalance in these voltages. It means that a set of unbalanced 3-phase, line-to-line voltages may be represented by a positive system and a negative system of balanced voltages. This fact is of considerable importance in the analysis of 3-phase rotating machinery. For example, the operation of an induction motor when supplied from an unbalanced system of 3-phase voltages, may be analysed on the basis of two balanced systems of voltages of opposite phase sequence.

Let us consider some typical 3-phase connections with reference to zero-sequence components of current and voltage.

(a) **Four-wire Star Connection.** Due to the presence of the fourth wire, the zero sequence currents may flow. The neutral wire carries only the zero-sequence current which is the sum of the zero-sequence currents in the three lines. Since the sum of line voltages is zero, there can be no zero sequence component of line voltages.

(b) **Three-wire Star Connection.** Since there is no fourth or return wire, zero-sequence components of current cannot flow. The absence of zero-sequence currents may be explained by considering that the impedance offered to these currents is infinite and that this impedance is situated between the star points of the generator and the load. If the two star points were joined by a neutral, only zero-sequence currents will flow through it so that only zero-sequence voltage can exist between the load and generator star points. Obviously, no zero-sequence component of voltage appears across the phase load.

(c) **Three-wire Delta Connection.** Due to the absence of fourth wire, zero-sequence components of currents cannot be fed into the delta-connected load. However, though line currents

have to sum up to zero (whereas phase currents need not do so) it is possible to have a zero-sequence current circulating in the delta-connected load.

Similarly, individual phase voltages will generally possess zero-sequence components though components are absent in the line-to-line voltage.\*

### 23.10. Unbalanced Star Load Supplied from Unbalanced Three-phase Three-wire System

In this case, line voltages and load currents will consist of only positive and negative-sequence components (but no zero-sequence component). But load voltages will consist of positive, negative and zero-sequence components.

Let the line voltages be denoted by  $V_{RY}$ ,  $V_{YB}$  and  $V_{BR}$ , line (and load) currents by  $I_R$ ,  $I_Y$  and  $I_B$ , the load voltages by  $V_{RN}$ ,  $V_{YN}$  and  $V_{BN}$  and load impedances by  $Z_R$ ,  $Z_Y$ , and  $Z_B$  (their values being the same for currents of any sequence).

Obviously,  $V_{RN} = I_R Z_R$ ;  $V_{YN} = I_Y Z_Y$  and  $V_{BN} = I_B Z_B$

If  $V_{RN1}$ ,  $V_{RN2}$  and  $V_0$  are the symmetrical components of  $V_{RN}$ , then we have

$$\begin{aligned} V_0 &= \frac{1}{3}(V_{RN} + V_{YN} + V_{BN}) = \frac{1}{3}(I_R Z_R + I_Y Z_Y + I_B Z_B) \\ &= \frac{1}{3}[Z_R(I_{R1} + I_{R2}) + Z_Y(I_{Y1} + I_{Y2}) + Z_B(I_{B1} + I_{B2})] \\ &= \frac{1}{3}[Z_R(I_{R1} + I_{R2}) + Z_Y(a^2 I_{R1} + a I_{R2}) + Z_B(a I_{R1} + a^2 I_{R2})] \\ &= I_{R1} \cdot \frac{1}{3}(Z_R + a^2 Z_Y + a Z_B) + I_{R2} \cdot \frac{1}{3}(Z_R + a Z_Y + a^2 Z_B) = I_{R1} Z_{R2} + I_{R2} Z_{R1} \end{aligned} \quad \dots (i)$$

$$\begin{aligned} V_{RN1} &= \frac{1}{3}(V_{RN} + a V_{YN} + a^2 V_{BN}) = \frac{1}{3}(I_R Z_R + a I_Y Z_Y + a^2 I_B Z_B) \\ &= \frac{1}{3}[Z_R(I_{R1} + I_{R2})] + a Z_Y(I_{Y1} + I_{Y2}) + a^2 Z_B(I_{B1} + I_{B2}) \\ &= I_{R1} \cdot \frac{1}{3}(Z_R + Z_Y + Z_B) + I_{R2} \cdot \frac{1}{3}(Z_R + a^2 Z_Y + a Z_B) = I_{R1} Z_0 + I_{R2} Z_{R2} \end{aligned} \quad \dots (ii)$$

$$V_{RN2} = I_{R2} Z_0 + I_{R1} Z_{R1}$$

Similarly,  $V_{YN1} = I_{Y1} Z_0 + I_{Y2} Z_{Y2} = a^2 (I_{R1} Z_0 + I_{R2} Z_{R2}) = a^2 V_{RN1}$

$$V_{BN1} = I_{B1} Z_0 + I_{B2} Z_{B2} = a (I_{R1} Z_0 + I_{R2} Z_{R2}) = a V_{RN1}$$

$$V_{YN2} = I_{Y2} Z_0 + I_{Y1} Z_{Y1} = a (I_{R2} Z_0 + I_{R1} Z_{R1}) = a V_{RN2}$$

$$V_{BN2} = I_{B2} Z_0 + I_{B1} Z_{B1} = a^2 (I_{R2} Z_0 + I_{R1} Z_{R1}) = a^2 V_{RN2}$$

Now,  $V_{RN1}$  and  $V_{RN2}$  may be determined from the relation between the line and phase voltages as given below:

$$V_{RY} = V_{RN} + V_{NY} = V_{RN} - V_{YN} = V_0 + V_{RN1} + V_{RN2} - (V_0 + V_{RN1} + V_{YN2})$$

\* However, under balanced conditions, the phase voltages will possess no zero-sequence components.

$$= \mathbf{V}_{RN1}(1-a^2) + \mathbf{V}_{RN2}(1-a) = \frac{1}{2}\sqrt{3}[\mathbf{V}_{RN1}(\sqrt{3} + j1) + \mathbf{V}_{RN2}(\sqrt{3} - j1)] \quad \dots (iii)$$

$$\begin{aligned} \mathbf{V}_{YB} &= \mathbf{V}_{YN} + \mathbf{V}_{NB} = \mathbf{V}_{YN} - \mathbf{V}_{BN} = \mathbf{V}_0 + \mathbf{V}_{YN1} + \mathbf{V}_{YN2} - (\mathbf{V}_0 + \mathbf{V}_{BN1} + \mathbf{V}_{BN2}) \\ &= \mathbf{V}_{RN1}(a^2 - a) - \mathbf{V}_{RN2}(a - a^2) = -j\sqrt{3} \cdot \mathbf{V}_{RN1} + j\sqrt{3}\mathbf{V}_{RN2} \end{aligned}$$

$$\therefore \mathbf{V}_{RN2} = \mathbf{V}_{RN1} - j\mathbf{V}_{YB} / \sqrt{3}$$

Substituting this value of  $\mathbf{V}_{RN2}$  in Eq. (iii) above and simplifying, we have

$$\mathbf{V}_{RN1} = \frac{1}{3}[\mathbf{V}_{RY} + \frac{1}{2}\mathbf{V}_{YB}(1 + j\sqrt{3})] \quad \dots (iv)$$

$$\mathbf{V}_{RN2} = \frac{1}{3}[\mathbf{V}_{RY} + \frac{1}{2}\mathbf{V}_{YB}(1 - j\sqrt{3})] \quad \dots (v)$$

Having known  $\mathbf{V}_{RN1}$  and  $\mathbf{V}_{RN2}$ , the currents  $\mathbf{I}_{R1}$  and  $\mathbf{I}_{R2}$  can be determined from the following equations:

$$\mathbf{I}_{R1} = \frac{(\mathbf{V}_{RN1}\mathbf{Z}_0 - \mathbf{V}_{RN2}\mathbf{Z}_{R2})}{\mathbf{Z}_0^2 - \mathbf{Z}_{R1}\mathbf{Z}_{R2}} \quad \dots (vi)$$

$$\mathbf{I}_{R2} = \frac{(\mathbf{Z}_{RN2}\mathbf{Z}_0 - \mathbf{V}_{RN1}\mathbf{Z}_{R1})}{\mathbf{Z}_0^2 - \mathbf{Z}_{R1}\mathbf{Z}_{R2}} \quad \dots (vii)$$

Alternatively, when  $\mathbf{I}_{R1}$  becomes known,  $\mathbf{I}_{R2}$  may be found from the relation

$$\mathbf{I}_{R2} = \frac{\mathbf{V}_{RN2} - \mathbf{I}_{R1}\mathbf{Z}_{R1}}{\mathbf{Z}_0} \quad \dots (viii)$$

The symmetrical components of the currents in other phases can be calculated from  $\mathbf{I}_{R1}$  and  $\mathbf{I}_{R2}$  by using the relations given in Art. 23.8.

The phase voltages may be calculated by any one of the two methods given below:

(i) directly by calculating the products  $\mathbf{I}_R\mathbf{Z}_R$ ,  $\mathbf{I}_Y\mathbf{Z}_Y$  and  $\mathbf{I}_B\mathbf{Z}_B$ .

(ii) by first calculating the zero-sequence component  $\mathbf{V}_0$  of the phase or load voltages and then adding this to the appropriate positive and negative sequence components.

For example,  $\mathbf{V}_{RN} = \mathbf{V}_0 + \mathbf{V}_{RN1} + \mathbf{V}_{RN2}$

### 23.11. Unbalanced Star Load Supplied from Balanced Three-phase, Three-wire System

It is a special case of the general case considered in Art. 23.10 above. In this case, the symmetrical components of the load voltages consist only of positive and zero-sequence components. This fact may be verified by substituting the value of  $\mathbf{V}_{YB}$  in Eq. (v) of Art. 23.10. Now, in a balanced or symmetrical system of positive-phase sequence

$$\mathbf{V}_{YB} = \mathbf{V}_{RY} \frac{1}{2} j\frac{\sqrt{3}}{2}$$

Substituting this value in Eq. (v) above, we have

$$\begin{aligned} \mathbf{V}_{RN2} &= \frac{1}{3}[\mathbf{V}_{RY} + \frac{1}{2}\mathbf{V}_{YB}(1 - j\sqrt{3})] \\ &= \frac{1}{3}\left[\mathbf{V}_{RY} + \frac{1}{2}\mathbf{V}_{RY}\left(-\frac{1}{2} - j\frac{\sqrt{3}}{2}\right)(1 - j\sqrt{3})\right] = \frac{1}{3}(\mathbf{V}_{RY} - \mathbf{V}_{RY}) = 0 \end{aligned}$$

Hence, substituting this value of  $V_{RN2}$  in Eq. (iv) and (vi) of Art. 23.10, we get

$$V_{RN1} = jV_{YB}\sqrt{3} = \frac{1}{2}V_{RY} - j\frac{1}{2}V_{RY}/\sqrt{3} \quad \dots (i)$$

$$I_{R1} = V_{RN1}Z_0 / (Z_0^2 - Z_{R1}Z_{R2}) = V_{RN1} \frac{Z_R + Z_Y + Z_B}{Z_R Z_Y + Z_Y Z_B + Z_B Z_R} \quad \dots (ii)$$

$$I_{R2} = -I_{R1} \cdot Z_{R1} / Z_0 = -I_{R1} = -I_{R1} \frac{Z_R + aZ_Y + a^2Z_B}{Z_R + Z_Y + Z_B} \quad \dots (iii)$$

Example 23.6 illustrates the procedure for calculating the current in an unbalanced star-connected load when supplied from a symmetrical three-wire system.

**Example 23.6.** A symmetrical 3-phase, 3-wire, 440-V system supplies an unbalanced Y-connected load of impedances  $Z_R = 5 \angle 30^\circ \Omega$ ;  $Z_Y = 10 \angle 45^\circ \Omega$ ,  $Z_B = 10 \angle 60^\circ \Omega$ . Phase sequence is  $R \rightarrow Y \rightarrow B$ . Calculate in the rectangular complex form the symmetrical components of the currents in the R-line. **(Elect. Engg.-I, Bombay Univ.)**

**Solution.** As shown in Fig. 23.4, the branch impedances are

Fig. 23.4

$$Z_R \quad 5 \quad 30 \quad (4.33 \quad j2.5)$$

$$Z_Y \quad 10 \quad 45 \quad (7.07 \quad j7.07)$$

$$Z_B \quad 10 \quad 60 \quad (5 \quad j8.66)$$

$$aZ_Y = 10 \angle 165^\circ = 10(-0.966 + j0.259) = -9.66 + j2.59 \Omega$$

$$a^2Z_Y \quad 10 \quad 75 \quad 10(0.259 \quad j0.966) \quad 2.59 \quad j9.66$$

$$aZ_B \quad 10 \quad 180 \quad (10 \quad j0)$$

$$a^2Z_B \quad 10 \quad 60 \quad 10(0.5 \quad j0.866) \quad (5 \quad j8.66)$$

The symmetrical component impedances required for calculation purposes are as follows:

$$Z_0 = \frac{1}{3}(Z_R \quad Z_Y \quad Z_B) = \frac{1}{3}(16.4 \quad j18.23) \quad (5.47 \quad j6.08)$$

$$\begin{aligned} Z_{R1} &= \frac{1}{3}(Z_R + Z_Y + a^2Z_B) \\ &= \frac{1}{3}(4.33 + j2.5 - 9.66 + j2.59 + 5 - j8.66) \\ &= \frac{1}{3}(-0.33 - j3.57) = -0.11 - j1.19 \end{aligned}$$

$$\begin{aligned} Z_{R2} &= \frac{1}{3}(Z_R + aZ_Y + aZ_B) \\ &= \frac{1}{3}(4.33 + j2.5 + 2.59 - j9.66 - 10 + j0) = \frac{1}{3}(-3.08 - j7.16) = -1.03 - j2.55 \end{aligned}$$

Now

$$\begin{aligned} \mathbf{Z}_0^2 \mathbf{Z}_{R1} \mathbf{Z}_{R2} &= \frac{1}{3} (\mathbf{Z}_R \mathbf{Z}_Y + \mathbf{Z}_Y \mathbf{Z}_B + \mathbf{Z}_B \mathbf{Z}_R) \\ &= \frac{1}{3} [50 \ 75 \ 100 \ 105 \ 50 \ 90] \begin{pmatrix} 4.31 & \\ & j65 \end{pmatrix} \end{aligned}$$

Let  $\mathbf{V}_{RY}$  be taken as the reference vectors so that  $\mathbf{V}_{RY} = (440 + j0)$

$$\text{Then, } \mathbf{V}_{RN1} = \frac{1}{2} \mathbf{V}_{RY} - j \frac{1}{2} \mathbf{V}_{RY} / \sqrt{3} = \frac{1}{2} (440 + j0) - j \frac{1}{2} (440 + j0) / \sqrt{3} = (220 - j127)$$

$$\text{Now, } \mathbf{I}_{R1} = \frac{\mathbf{V}_{RN1} \cdot \mathbf{Z}_0}{(\mathbf{Z}_0^2 \mathbf{Z}_{R1} \mathbf{Z}_{R2})} = \frac{(220 \ j127) \begin{pmatrix} 5.47 & \\ & j6.08 \end{pmatrix}}{\begin{pmatrix} 4.31 & \\ & j65 \end{pmatrix}} = \frac{1986 \ j643}{\begin{pmatrix} 4.31 & \\ & j65 \end{pmatrix}}$$

$$= \frac{2088 \angle 18^\circ}{66.4 \angle 93.8^\circ} = 31.6 \angle -75.8^\circ = (7.75 - j30.6) \text{ A}$$

$$\mathbf{I}_{R2} = -\mathbf{I}_{R2} \mathbf{Z}_{R1} / \mathbf{Z}_0$$

$$= \frac{-(7.75 - j30.6)(-0.11 - j1.19)}{(5.47 + j6.08)} = \frac{(37.25 + j5.88)}{(5.47 + j6.08)}$$

$$= \frac{37.75 \angle 9^\circ}{8.18 \angle 48^\circ} = 4.61 \angle -39^\circ = (3.28 - j2.66) \text{ A}$$

Hence, the symmetrical components of  $\mathbf{I}_R$  are:-

Positive-sequence component =  $(7.75 - j30.6) \text{ A}$

Negative-sequence component =  $(3.28 - j2.66) \text{ A}$

**Note. (i)**  $\mathbf{I}_R = \mathbf{I}_{R1} + \mathbf{I}_{R2}$

**(ii)** Symmetrical components of other currents are

$$\mathbf{I}_Y = a^2 \mathbf{I}_{B1} \text{ and } \mathbf{I}_{Y2} = a \mathbf{I}_{R2}; \mathbf{I}_{B1} = a \mathbf{I}_{R1} \text{ and } \mathbf{I}_{B2} = a^2 \mathbf{I}_{R2}$$

**Example 23.7.** A balanced star-connected load takes 75 A from a balanced 3-phase, 4-wire supply. If the fuses in two of the supply lines are removed, find the symmetrical components of the line currents before and after the fuses are removed.

**Solution.** The circuit is shown in Fig. 23.5.

Fig. 23.5

**Before fuses are removed**

$$\mathbf{I}_R \ 75 \ 0; \mathbf{I}_Y \ 75 \ 120; \mathbf{I}_B \ 75 \ 120$$

$$\mathbf{I}_1 = \frac{1}{3} (\mathbf{I}_R \ a \mathbf{I}_Y \ a^2 \mathbf{I}_B) = \frac{1}{3} (75 \ 0 \ 75 \ 0 \ 75 \ 360) = 75 \ 0 \ \text{A}$$

$$\mathbf{I}_2 = \frac{1}{3} (\mathbf{I}_R \ a^2 \mathbf{I}_Y \ a \mathbf{I}_B) = \frac{1}{3} (75 \ 0 \ 75 \ 120 \ 75 \ 240) = 0$$

$$\mathbf{I}_0 = \frac{1}{3} (\mathbf{I}_R \ \mathbf{I}_Y \ \mathbf{I}_B) = \frac{1}{3} (75 \ 0 \ 75 \ 120 \ 75 \ 120) = 0.$$

After fuses are removed

$$\mathbf{I}_R = 75 \angle 0^\circ; \mathbf{I}_Y = \mathbf{I}_B = 0$$

$$\mathbf{I}_1 = \frac{1}{3} (75 \ 0 \ 0 \ 0) = 25 \ 0$$

$$\mathbf{I}_2 = 25\angle 0^\circ, \mathbf{I}_0 = 25\angle 0^\circ$$

**Example 23.8.** Explain the terms: positive-, negative- and zero-sequence components of a 3-phase voltage system. A star-connected load consists of three equal resistors, each of  $1 \Omega$  resistance. When the load is connected to an unsymmetrical 3-phase supply, the line voltages are 200 V, 346 V and 400 V.

Find the magnitude of the current in any one phase by the method of symmetrical components. **(Power Systems-II, A.M.I.E.)**

**Solution.** This question could be solved by using the following two methods:

(a) As shown in Fig. 23.6(a), the line voltages form a closed right-angled triangle with an angle =  $\tan^{-1}(346/200) = \tan^{-1}(1.732) = 60^\circ$

Hence, if  $\mathbf{V}_{AB} = 200 \angle 0^\circ$ , then  $\mathbf{V}_{BC} = 346 \angle -90^\circ = -j346$  and  $\mathbf{V}_{CA} = 400 \angle 120^\circ$ .

As seen from Eq. (iv) and (v) of Art. 23.10

$$\begin{aligned} \mathbf{V}_{AN1} &= \frac{1}{3} \left[ \mathbf{V}_{AB} + \frac{1}{2} \mathbf{V}_{BC} (1 + j\sqrt{3}) \right] \\ &= \frac{1}{3} \left[ 200 + \left( \frac{1}{2} + j\frac{\sqrt{3}}{2} \right) (-j346) \right] = 166.7 - j57.7 \end{aligned}$$

$$\begin{aligned} \mathbf{V}_{AN2} &= \frac{1}{3} \left[ \mathbf{V}_{AB} + \mathbf{V}_{BC} \left( \frac{1}{2} - \frac{j\sqrt{3}}{2} \right) \right] \\ &= \frac{1}{3} \left[ 200 + \left( \frac{1}{2} - j\frac{\sqrt{3}}{2} \right) (-j346) \right] = -33.3 - j57.7 \end{aligned}$$

Fig. 23.6

Now,  $\mathbf{Z}_A + \mathbf{Z}_B + \mathbf{Z}_C = 3$

$$\mathbf{Z}_{A1} = \mathbf{Z}_A + a\mathbf{Z}_B + a^2\mathbf{Z}_C = 0 \text{ (because } \mathbf{Z}_A = \mathbf{Z}_B = \mathbf{Z}_C \text{ and } 1 + a + a^2 = 0)$$

Similarly,  $\mathbf{Z}_{A2} = \mathbf{Z}_A + a^2\mathbf{Z}_B + a\mathbf{Z}_C = 0$

Hence, from Eq. (ii) of Art. 23.10 we have  $\mathbf{V}_{AN1} = \mathbf{I}_{A1}\mathbf{Z}_0 \therefore \mathbf{I}_{A1} = \mathbf{V}_{AN1}/\mathbf{Z}_0$

$$\text{Now, } \mathbf{Z}_0 = \frac{1}{3}(\mathbf{Z}_A + \mathbf{Z}_B + \mathbf{Z}_C) = 3/3 = 1 \therefore \mathbf{I}_{A1} = (166.7 - j57.7) \text{ A}$$

$$\mathbf{I}_{A2} = \mathbf{V}_{AN2}/\mathbf{Z}_0 = -33.3 - j57.7 \therefore \mathbf{I}_A = \mathbf{I}_{A1} + \mathbf{I}_{A2} \quad (\mathbf{I}_0 = 0)$$

$$\therefore \mathbf{I}_A = (166.7 - j57.7) + (-33.3 - j57.7) = 133.4 - j115.4 = 176.4 \angle 40.7^\circ \text{ A}$$

(b) Using Millman's theorem and taking the line terminal  $A$  as reference point, the voltage between  $A$  and the neutral point  $N$  is

$$\mathbf{V}_{NA} = \frac{\mathbf{V}_{BA} \mathbf{Y}_B + \mathbf{V}_{CA} \mathbf{Y}_C}{\mathbf{Y}_A + \mathbf{Y}_B + \mathbf{Y}_C} = \frac{200 \angle 180^\circ \cdot 1 + 400 \angle 120^\circ \cdot 1}{3} = 133.3 - j115.3 \text{ V}$$

$$\mathbf{V}_{AN} = 176.4 - j139.3 \text{ V} \quad \mathbf{I}_A = \mathbf{I}_{AN} / \mathbf{Z} = 176.4 - j40.7 \text{ A} \quad \dots \text{ as before}$$

**Example 23.9.** Three equal impedances of  $(8 + j6)$  are connected in star across a 3-phase, 3-wire supply. The phase voltages are  $V_A = (220 + j0)$ ,  $V_B = (-j220)$  and  $V_C = (-100 + j220)$  V. If there is no connection between the load neutral and the supply neutral, calculate the symmetrical components of A-phase current and the three line currents.

**Solution.** Since there is no fourth wire, there is no zero-component current. Moreover,  $\mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C = 0$ . The symmetrical components of the A-phase voltages are

$$\mathbf{V}_0 = \frac{1}{3}(220 - j220 - 100 + j220) = 40 \text{ V}^*$$

$$\mathbf{V}_{A1} = \frac{1}{3}[220 + (0.5 - j0.866)(-j220) + (0.5 + j0.866)(-100 + j220)]$$

$$= \frac{1}{3}[(660 + j86.6)] = (220 + j28.9) \text{ V}$$

$$\mathbf{V}_{A2} = \frac{1}{3}[220 + (0.5 + j0.866)(-j220) + (0.5 - j0.866)(-100 + j220)]$$

$$= \frac{1}{3}(-120 - j86.6) = (-40 - j28.9) \text{ V}$$

The component currents in phase A are

$$\mathbf{I}_{A1} = \frac{\mathbf{V}_{A1}}{(8 + j6)} = \frac{220 + j28.9}{(8 + j6)} = (19.33 - j10.89) \text{ A}$$

$$\mathbf{I}_{A2} = \frac{\mathbf{V}_{A2}}{(8 - j6)} = \frac{(-40 - j28.9)}{(8 - j6)} = (4.93 + j0.09) \text{ A}$$

$$\mathbf{I}_A = \mathbf{I}_{A1} + \mathbf{I}_{A2} = (14.4 - j10.8) \text{ A}; \mathbf{I}_B = \mathbf{I}_{B1} + \mathbf{I}_{B2} = a^2 \mathbf{I}_{A1} + a \mathbf{I}_{A2}$$

$$\mathbf{I}_B = \frac{1}{2} - j\frac{\sqrt{3}}{2} (19.33 - j10.89) + \frac{1}{2} + j\frac{\sqrt{3}}{2} (4.93 + j0.09)$$

**Example 23.10.** Two equal impedance arms  $AB$  and  $BC$  are connected to the terminals  $A$ ,  $B$ ,  $C$  of a 3-phase supply as shown in Fig. 23.7. Each capacitor has a reactance of  $X = \sqrt{3}R$ . A high impedance voltmeter  $V$  is connected to the circuit at points  $P$  and  $Q$  as shown. If the supply line voltages  $V_{AB}$ ,  $V_{BC}$ ,  $V_{CA}$  are balanced, determine the reading of the voltmeter (a) when the phase sequence of the supply voltages is  $A \rightarrow B \rightarrow C$  and (b) when the phase sequence is reversed. Hence, explain how this network could be employed to measure, respectively, the positive and negative phase sequence voltage components of an unbalanced 3-phase supply.

\* However, it is not required in the problem.

**Solution.** The various currents and voltages are shown in Fig. 23.7.

### Phase Sequence ABC

Fig. 23.7

Taking  $\mathbf{V}_{AB}$  as the reference vector, we have

$$\mathbf{V}_{AB} = V(1 + j0); \mathbf{V}_{BC} = a^2V; \mathbf{V}_{CA} = aV$$

As seen from the diagram,

$$\mathbf{I}_{AB} = \frac{\mathbf{V}_{AB}}{3R + jX} = \frac{V}{3R + j\sqrt{3}R} = \frac{V}{\sqrt{3}R(\sqrt{3} + j)}$$

$$\mathbf{I}_{BC} = \frac{\mathbf{V}_{BC}}{3R + jX} = \frac{a^2V}{\sqrt{3}R(\sqrt{3} + j)}$$

$$\text{Now, } \mathbf{V}_{PO} + \mathbf{V}_{OQ} = \mathbf{V}_{PQ}$$

$$\text{Also, } \mathbf{V}_{PQ} = \mathbf{I}_{AB}(R - jX) + \mathbf{I}_{BC}.2R$$

$$= \frac{V}{\sqrt{3}R(\sqrt{3} + j)}.R(1 - j\sqrt{3}) + \frac{a^2V}{\sqrt{3}R(\sqrt{3} + j)}.2R$$

$$= \frac{V}{\sqrt{3}(\sqrt{3} + j)}.(1 - j\sqrt{3} + 2a^2) \quad a^2 \quad \frac{1}{2} \quad j\frac{\sqrt{3}}{2}$$

$$= \frac{V}{\sqrt{3}(\sqrt{3} + j)}.(-j2\sqrt{3}) \quad \therefore V_{PQ} = \frac{V}{\sqrt{3}} \cdot \frac{1}{2} \cdot 3\sqrt{3} = V$$

Hence, the voltmeter which is not phase sensitive will read the line voltage when phase sequence is  $A \rightarrow B \rightarrow C$ .

### Phase Sequence ACB

$$\text{In this case, } \mathbf{V}_{AB} = V(1 + j0); \mathbf{V}_{BC} = aV; \mathbf{V}_{CA} = a^2V$$

$$\text{Also, } \mathbf{V}_{PQ} = \mathbf{V}_{PO} + \mathbf{V}_{OQ}$$

$$= \mathbf{I}_{AB}(R - jX) + \mathbf{I}_{BC}.2R = \frac{V(R - jX)}{\sqrt{3}.R(\sqrt{3} + j)} + \frac{aV.2R}{\sqrt{3}.R(\sqrt{3} + j)}$$

$$= \frac{V}{\sqrt{3}(\sqrt{3} + j)}(1 - j\sqrt{3} + 2a) = \frac{V}{\sqrt{3}(\sqrt{3} + j)}(1 - j\sqrt{3} - 1 + j\sqrt{3}) = 0$$

Hence, when the phase sequence is reversed, the voltmeter reads zero.

It can be proved that with sequence  $ABC$ , the voltmeter reads the positive sequence component ( $\mathbf{V}_1$ ) and with phase sequence  $ACB$ , it reads the negative sequence component ( $\mathbf{V}_2$ ) with phase sequence  $ABC$

$$\mathbf{V}_{PQ} = \frac{\mathbf{V}_{AB}}{3R + j\sqrt{3}R}(R - j\sqrt{3}R) + \frac{\mathbf{V}_{BC}}{3R + j\sqrt{3}R}.2R = \frac{1}{3} \frac{1}{j\sqrt{3}} [(\mathbf{V}_1 \quad \mathbf{V}_2)(1 \quad j\sqrt{3}) \quad 2(a^2\mathbf{V}_1 \quad a\mathbf{V}_2)]$$

$$= \frac{1}{3 - j\sqrt{3}} [\mathbf{V}_1(1 - j\sqrt{3} + 2a^2) + \mathbf{V}_2(1 - j\sqrt{3} + 2a)] = \frac{1}{3 - j\sqrt{3}} \mathbf{V}_1(-j2\sqrt{3}) \quad \therefore \mathbf{V}_{PQ} = \mathbf{V}_1$$

With phase sequence  $ACB$

$$\begin{aligned} \mathbf{V}_{PQ} &= \frac{1}{3-j\sqrt{3}} [(\mathbf{V}_1 \ \mathbf{V}_2) (1 \ j\sqrt{3}) \ 2(a \ \mathbf{V}_1 \ a^2 \ \mathbf{V}_2)] \\ &= \frac{1}{3-j\sqrt{3}} [\mathbf{V}_1(1-j\sqrt{3}+2a) + \mathbf{V}_2(1-j\sqrt{3}+2a^2)] \\ &= \frac{1}{3-j\sqrt{3}} [\mathbf{V}_2(-j2\sqrt{3})] \therefore V_{PQ} = V_2 \end{aligned}$$

### 23.12. Measurement of Symmetrical Components of Circuits

The apparatus consists of two identical current transformers, two impedances of the same ohmic value, one being more inductive than the other to the extent that its phase angle is  $60^\circ$  greater and two identical ammeters  $A_1$  greater and two identical ammeters  $A_1$  and  $A_2$  as shown in Fig. 23.8 (a). It can be shown that  $A_1$  reads positive-sequence current only while  $A_2$  reads negative-sequence current only. If the turn ratio of the current transformer is  $K$ , then keeping in mind that zero-sequence component is zero, we have

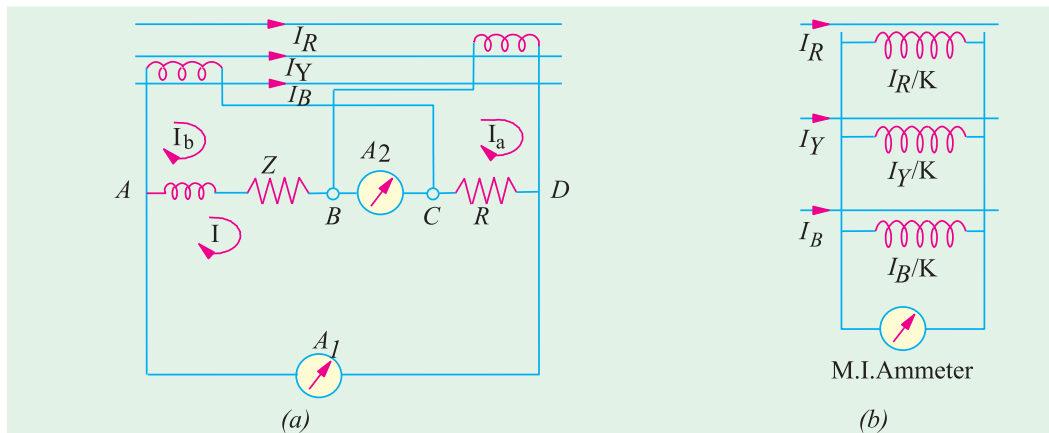

Fig. 23.8

$$\mathbf{I}_a = \mathbf{I}_R / K = (\mathbf{I}_1 + \mathbf{I}_2) / K$$

where  $\mathbf{I}_1$  and  $\mathbf{I}_2$  are the positive and negative-sequence components of the line current respectively.

Similarly,

$$\mathbf{I}_b = \mathbf{I}_Y / K = (a^2 \mathbf{I}_1 + a \mathbf{I}_2) / K$$

If the impedance of each ammeter is  $R_A + jX_A$ , then impedance between points  $B$  and  $D$  is

$$\mathbf{Z}_{BD} = (R \ R_A \ jX_A)$$

The value of  $\mathbf{Z}$  is so chosen that

$$\mathbf{Z}_{AC} = \mathbf{Z} \ R_A \ jX_A = (R \ R_A \ jX_A) \ 60 \ \mathbf{Z}_{BD} \ 60$$

For finding the current read by  $A_1$ , imagine a break at point  $X$ . Thevenin voltage across the break  $X$  is

Current transformers

$V_{th} = I_b Z_{AC} + I_a Z_{BD} = I_b Z_{BD} = I_b Z_{BD} \angle 60^\circ + I_a Z_{BD} = (I_b \angle 60^\circ + I_a) Z_{BD}$   
 Total impedance in series with this Thevenin voltage is

$$Z_T = Z_{AC} + Z_{BD} + Z_{BD} = 60 + Z_{BD} + \frac{3}{2} j \frac{\sqrt{3}}{2} Z_{BD}$$

The current flowing normally through the wire in which a break has been imagined is

$$\begin{aligned} I &= \frac{V_{th}}{Z_T} = \frac{I_b \angle 60^\circ + I_a}{(3/2) + j(\sqrt{3}/2)} = \frac{1}{K} \frac{(a^2 I_1 + a I_2) \angle 60^\circ + I_1 + I_2}{\sqrt{3} \angle 30^\circ} \\ &= \frac{1}{K} \frac{I_1 (1 \ 300 \ 1) \ I_2 (1 \ 180 \ 1)}{\sqrt{3} \ 30} = \frac{I_1}{K} \ 60 \end{aligned}$$

It means that  $A_1$  reads positive-sequence current only. The ammeter  $A_2$  reads current which is

$$\begin{aligned} &= I_a \ I_b \ I = \frac{1}{K} (I_1 + I_2 + I_1 \angle 240^\circ + I_2 \angle 120^\circ - I_2 \angle -60^\circ) \\ &= \frac{I_1}{K} \left( 1 - \frac{1}{2} - j \frac{\sqrt{3}}{2} - \frac{1}{2} + j \frac{\sqrt{3}}{2} \right) + \frac{I_2}{K} (1 + 1 \angle 120^\circ) = \frac{I_2}{K} \angle 60^\circ \end{aligned}$$

In other words,  $A_2$  reads negative-sequence current only.

Now, it will be shown that the reading of the moving-iron ammeter of Fig. 23-8(b) is proportional to the zero-sequence component.

$$\begin{aligned} I_0 &= \frac{1}{3} (I_R + I_Y + I_B) = \frac{K}{3} \left( \frac{I_R}{K} + \frac{I_Y}{K} + \frac{I_B}{K} \right) \\ &= \frac{K}{3} \times (\text{current through the ammeter}) = \frac{K}{3} \times \text{ammeter reading.} \end{aligned}$$

It is obvious that for  $I_0$  to be present, the system must be 3-phase, 4-wire. However, when the fourth wire is available, then  $I_0$  may be found directly by finding the neutral current  $I_N$ . In that case  $I_0 = \frac{1}{3} I_N$ .

### 23.13. Measurement of Positive and Negative-sequence \*Voltages

With reference to Fig. 23.9 (a), it can be shown that the three voltmeters indicate only the positive-sequence component of the 3-phase system.

Fig. 23.9

\* It is supposed to possess infinite impedance.

The line-to-neutral voltage can be written (with reference to the red phase) as

$$\mathbf{V}_{RN} = \mathbf{V}_1 + \mathbf{V}_2 + \mathbf{V}_0; \mathbf{V}_{YN} = a^2\mathbf{V}_1 + a\mathbf{V}_2 + \mathbf{V}_0; \mathbf{V}_{BN} = a\mathbf{V}_1 + a^2\mathbf{V}_2 + \mathbf{V}_0$$

$$\mathbf{V}_{RY} = \mathbf{V}_{RN} + \mathbf{V}_{NY} = \mathbf{V}_{RN} - \mathbf{V}_{YN} = (1-a^2)\mathbf{V}_1 + (1-a)\mathbf{V}_2$$

$$\mathbf{V}_{YB} = \mathbf{V}_{YN} + \mathbf{V}_{NB} = \mathbf{V}_{YN} - \mathbf{V}_{BN} = (a^2-a)\mathbf{V}_1 + (a-a^2)\mathbf{V}_2$$

$$\therefore \mathbf{V}_{DY} = \frac{\mathbf{V}_{RY}(r \ 1/j \ C)}{(R \ r \ 1/j \ C)} \quad \mathbf{V}_{YE} = \frac{\mathbf{V}_{YB} \cdot R}{(R \ r \ 1/j \ C)}$$

$$\therefore \mathbf{V}_{DE} = \frac{(r \ 1/j \ C)}{(R \ r \ 1/j \ C)} \mathbf{V}_{RY} - \frac{R}{(r \ 1/j \ C)} \mathbf{V}_{YB}$$

The different equation of the bridge circuit are so chosen that

$$\frac{R}{r + j1/\omega C} = -a^2 = \frac{1}{2} + j \frac{\sqrt{3}}{2} \quad \text{or} \quad R = \frac{r}{2} + \frac{\sqrt{3}}{2\omega C} + \frac{1}{j2\omega C} + j \frac{\sqrt{3}r}{2}$$

Equating the  $j$ -terms or quadrature terms on both sides, we have

$$0 = \frac{1}{j2\omega C} + j \frac{\sqrt{3}}{2} \quad \therefore \frac{1}{\omega C} = \sqrt{3}r \quad \dots (i)$$

Similarly, equating the reference or real terms, we have

$$R = \frac{r}{2} + \frac{\sqrt{3}}{2\omega C} = \frac{r}{2} + \frac{3r}{2} = 2r \quad \dots (ii)$$

$$\therefore \frac{r + 1/j\omega C}{R + r + 1/\omega C} = \frac{r - j\sqrt{3}r}{3r - j\sqrt{3}r} = \frac{r(1 - j\sqrt{3})}{r(3 - j\sqrt{3})} = \frac{1}{\sqrt{3}} \angle -30^\circ$$

$$\text{and} \quad \mathbf{V}_{DE} = \frac{1 \angle -30^\circ}{\sqrt{3}} [(1-a^2)\mathbf{V}_1 + (1-a)\mathbf{V}_2 - a^2(a^2-a)\mathbf{V}_1 - a^2(a-a^2)\mathbf{V}_2]$$

$$= \frac{1 \angle -30^\circ}{\sqrt{3}} (1-a^2 - a^4 + a^3)\mathbf{V}_1$$

$$[1 - a = a^2(a - a^2)] = \sqrt{3}\mathbf{V}_1 \angle -30^\circ$$

Hence, the voltmeter connected between points  $D$  and  $E$  measures  $\sqrt{3}$  times the positive sequence component of the phase voltage. So do the other two voltmeters.

In Fig. 23.9 (b), the elements have been reversed. It can be shown that provided the same relation is maintained between the elements, the high impedance voltmeter measures  $\sqrt{3}$  times the negative-sequence component of phase voltage.

### 23.14. Measurement of Zero-sequence Component of Voltage

The zero-sequence voltage is given by

$$\mathbf{V}_0 = \frac{1}{3}(\mathbf{V}_{RN} + \mathbf{V}_{YN} + \mathbf{V}_{BN})$$

Fig. 23.10

Fig. 23.10 indicates one method of measuring  $V_0$ . As seen

$$V_{N'N} = \frac{V_{RN}Y + V_{YN}Y + V_{BN}Y}{3Y}$$

$$= \frac{1}{3}(V_{RN} + V_{YN} + V_{BN}) = V_0$$

Hence, voltmeter connected between the neutral points measures the zero-sequence component of the voltage.

### Tutorial Problem No. 23.2

1. Explain the essential features in the representation of an unsymmetrical three-phase system of voltages or currents by symmetrical components.

In a three-phase system, the three line currents are;  $I_R = (30 + j50)A$ ,  $I_Y = (15 - j45)A$ ,  $I_B = (-40 + j70)A$ .

A. Determine the values of the positive, negative and zero sequence components.

[52.2 A, 19.3 A, 25.1 A] (London Univ.)

2. The phase voltages of a three-phase, four-wire system are;  $V_{RN} = (200 + j0) V$ ,  $V_{YN} = (0 - j200) V$ ,  $V_{BN} = (-100 + j100) V$ . Show that these voltages can be replaced by symmetrical components of positive, negative and zero sequence and calculate the magnitude of each component.

Sketch vector diagrams representing the positive, negative and zero-sequence components for each of the three phases.

[176 V, 38 V, 47.1 V] (London Univ.)

3. Explain, with the aid of a diagram of connections, a method of measuring the symmetrical components of the currents in an unbalanced 3-phase, 3-wire system.

If in such a system, the line currents, in amperes, are

$$I_R = (10 - j2), I_Y = (-2 - j4), I_B = (-8 + j6)$$

Calculate their symmetrical components.

$$[I_{R0} = I_{Y0} = I_{B0} = 0; I_{R1} = 7.89 + j0.732; I_{Y1} = a^2 I_{R1}; I_{B1} = a I_{R1}; I_{R2} = 2.113 - j2.732; I_{Y2} = a I_{R2}; I_{B2} = a^2 I_{R2}]$$

### OBJECTIVE TESTS – 23

- The method of symmetrical components is very useful for
  - solving unbalanced polyphase circuits
  - analysing the performance of 3-phase electrical machinery
  - calculating currents resulting from unbalanced faults
  - all of the above
- An unbalanced system of 3-phase voltages having *RYB* sequence actually consists of
  - a positive-sequence component
  - a negative-sequence component
  - a zero-sequence component
  - all of the above.
- The zero-sequence component of the unbalanced 3-phase system of vectors  $V_A$ ,  $V_B$  and  $V_C$  is .... of their vector sum.
  - one-third
  - one-half
  - two-third
  - one-fourth
- In the case of an unbalanced star-connected load supplied from an unbalanced 3- $\phi$ , 3 wire system, load currents will consist of
  - positive-sequence components
  - negative-sequence components
  - zero-sequence components
  - only (a) and (b).

## INTRODUCTION TO ELECTRICAL ENERGY GENERATION

Electricity is generated at power plants and transmitted to different substations from where it will be distributed to individual customers

### 24.1. Preference for Electricity

Energy is vital for all living-beings on earth. Modern life-style has further increased its importance, since a faster life means faster transport, faster communication, and faster manufacturing processes. All these lead to an increase in energy required for all those modern systems.

Arising out of comparison of status of nations, the progress is related in terms of per capita consumption of electrical energy (i.e. kWh consumed per person per year). At present, this parameter for India is about 300, for UK it is 12 to 15 times more, and for USA, it is about 30 times more.

It simply means that Electrical energy is the most popular form of energy, whether we require it in the usable thermal form (= heating applications), in mechanical form (= electrical motor-applications in Industries), for lighting purposes (= illumination systems), or for transportation systems.

Following are the main reasons for its popularity.

1. Cleaner environments for user
2. Higher efficiency
3. Better controllability
4. Easier bulk-power, long-distance transportation of power using overhead transmission or underground cables
5. Most versatile devices of energy conversions from Electrical to other forms are available for different purposes, such as thermal, illumination, mechanical, sound, chemical, etc.

### 24.2. Comparison of Sources of Power

While selecting a method of generating electricity, following factors are taken into account for purposes of comparison:

- (a) Initial cost: For a given rating of a unit (in the minds of planners), investment must be known. Naturally, lower the initial cost, better it is.
- (b) Running Cost:- To produce a given amount of electrical energy, the cost of conversion process (including proportional cost of maintenance/repairs of the system) has to be known.
- (c) Limitations:- Whether a particular resource is available, whether a unit size of required rating is available from a single unit or from an array of large number of units, and whether a particular method of generation is techno-economically viable and is time-proven, are typical queries related to the limitations of the concerned method.
- (d) (1) perpetuity, (2) efficiency, (3) reliability, (4) cleanliness and (5) simplicity.

It is naturally desirable that the source must have perpetuity (= be of endless duration), high conversion efficiency, and reliability (in terms of availability in appropriate quantity). The energy conversion must be through a cleaner process (specially from the view- points of toxicity, pollution or any other hazardous side effects). Further, a simpler overall system is always preferred with regards to maintenance/repairs problems and is supposed to be more reliable.

### 24.3. Sources for Generation of Electricity

Following types of resources are available for generating electrical energy (No doubt, this list can be extended to include some more up-coming resources. The following list, however, gives the popular and potential resources).

#### (a) Conventional methods

- (a) **Thermal:** Thermal energy (from fossil fuels) or Nuclear Energy used for producing steam for turbines which drive the alternators (= rotating a.c. generators).
- (b) **Hydro-electric:** Potential of water stored at higher altitudes is utilized as it is passed through water-turbines which drive the alternators.

#### (b) Non-conventional methods

- (c) **Wind power:** High velocities of wind (in some areas) are utilized in driving wind turbines coupled to alternators. Wind power has a main advantage of having zero production cost. The cost of the equipment and the limit of generating-unit-rating is suitable for a particular

location (= geographically) are the important constraints. This method has exclusive advantages of being pollution free and renewable. It is available in plentiful quantity, at certain places. It suffers from the disadvantages of its availability being uncertain (since dependent on nature) and the control being complex (since wind-velocity has wide range of variation, as an input, and the output required is at constant voltage and constant frequency). Single large-power units cannot be planned due to techno-economic considerations.

Use of Wind Powder

- (d) **Fuel cells:** These are devices which enable direct conversion of energy, chemically, into electrical form. This is an up-coming technology and has a special merit of being pollution-free and noise-free. It is yet to become popular for bulk-power generation.
- (e) **Photo voltaic cells:** These directly convert solar energy into electrical energy through a chemical action taking place in solar cells. These operate based on the photo-voltaic effect, which develops an emf on absorption of ionizing radiation from Sun.

### Power Scenario In India:-

Following approximate statistical data give an idea about some aspects in this regard.

Total installed capacity	:	150,000 MW
Hydropower	:	50,000 MW
Nuclear	:	10,000 MW
Thermal (fossil fuels)	:	80,000 MW
Other methods	:	10,000 MW

Other methods include partly exploited Potential such as Wind, Solar, Co-generation, Methods using Bio-fuels, etc.

## 24.4. Brief Aspects of Electrical Energy Systems

### 24.4.1. Utility and Consumers

At generating stations, power is generated at the best locations. Load-centres are generally away from these. Generation-units and Loads are connected by transmission systems. Thus, the energy system is divided into two main parts.

- (a) Utility (including sources and transmission network) and,  
 (b) Consumers (who utilize the electrical energy)

### 24.4.2. Why is the three- phase a. c. system most popular?

- (a) It is well known that a.c. generation is simpler (than d.c. generation through electrical machines because of absence of commutators in a.c. machines). Further, mechanical commutation system in d.c. machines sets an upper limit of their size, while the rating of the individual generators in **modern power stations** is too large, say about 1500 times the rating of a single largest feasible d.c. machine. A.C. further facilitates in stepping down or stepping-up of a voltage to suit a particular requirement, with the help of a simple device, the well-known transformer.
- (b) Changing over from a.c. to d.c. is very easy these days due to the rectifiers of sufficiently high power ratings, so that a wide range of d.c. – applications can now be catered to.
- (c) As the number of phases goes on increasing the power-output (from a device using a given quantity of active material, namely, that used for core and for winding) increases, but the number of circuits (*i.e.* connecting lines/ wires, switches, etc) also increases. These two points are contradictory. A choice will be in favour of such a number (of phases) which will be high enough from power-output point of view but low enough from viewpoints

of complexity of connecting/controlling large number of phases. There is a Golden compromise. It has resulted into popularity of the three-phase a. c. systems over the entire time period. Now it has almost become a standard practice for all purposes.

#### 24.4.3. Cost of Generation

Cost of generation for one unit of electrical energy depends on the method of generation, formulae worked to assess its running cost under the specified conditions, and the cost of transmission line loss to transport power upto the load. These days, a modern utility (= electricity board) has a large number of generators sharing the responsibility of supplying power to all the customers connected to the Grid (= common supply-network). Then, for an increase in load-demand, at a known location, the most economical generating unit is to be identified and that unit should be monitored to meet the increased demand.

#### 24.4.4. Staggering of Loads during Peak-demand Hours

Incentives to consumers (by way of supplying at reduced rates during light load hours e.g. Late night 'hours, after noon hours) help in even demand throughout the day.

#### 24.4.5. Classifications of Power Transmission

- (a) Using underground cables or using overhead transmission lines.
- (b) Extra High Voltage A.C.-versus-Extra High Voltage D.C. transmission systems.

#### 24.4.6. Selecting A.C. Transmission Voltage for a Particular Case

In general, for transporting a given power of  $VI$  watts, either  $V$  can be high or  $V$  can be low. Accordingly, the current can be either low or high respectively. Higher voltage means higher cost of insulation, and larger clearances. Higher current means larger cross section of conductors. Considering these together, the most economical voltage has to be found out for a particular requirement.

Kelvin's Laws give a guideline for this. (These are discussed in Art. 47.21 in Vol. III, of this book).

### 24.5. Conventional Sources of Electrical Energy

Thermal (coal, gas, nuclear) and hydro-generations are the main conventional methods of generation of Electrical Energy. These enjoy the advantages of reaching perfections in technologies for these processes. Further, single units rated at large power-outputs can be manufactured along with main components, auxiliaries and switch-gear due to vast experiences during the past century. These are efficient and economical.

These suffer from the disadvantages listed below:

1. The fuels are likely to be depleted in near future, forcing us to conserve them and find alternative resources.
2. Toxic, hazardous fumes and residues pollute the environment.
3. Overall conversion efficiency is poor.
4. Generally, these are located at remote places with respect to main load centres, increasing the transmission costs and reducing the system efficiency.
5. Maintenance costs are high.

Out of these, only two such types will be dealt here, which have a steam turbine working as the prime mover. While remaining two use Internal Combustion Engines (I.C. engines) or Gas turbine as the prime mover, and these will *not* be dealt with, in this Introductory treatment.

The steam-turbine driven systems are briefly discussed below.

#### 24.5.1. Steam Power Stations (Coal-fired)

India has rich stocks of coal as a natural resource. Chemical energy stored within the coal is finally transformed into Electrical energy through the process of these stations. Heat released by the combustion of coal produces steam in a boiler at elevated temperatures and pressures. It is then passed through steam turbines, which drive the alternator, the output of which is the electrical energy.

Figure 24.1 shows a simple schematic diagram of a modern coal-fired thermal station.

In India, coal is generally of low grade containing ash upto 40 %. It poses two problems.

(i) Calorific value is low and hence system efficiency can be increased only by additional processes like pulverizing the coal and using oil firing to start with, (ii) large volumes of ash have to be handled after ensuring that ash is extracted to the maximum possible extent (upto 99 %) by using electrostatic precipitators, before flue gases from boiler are finally passed on to the atmosphere.

Coal is burnt in the boiler. This heat converts water into steam when passed through the boiler tubes. Modern plants have super heaters to raise the temperature and pressure of steam so that plant efficiency is increased. Condenser and cooling tower deal with steam coming out of turbine. Here, maximum heat is extracted from steam (which then takes the form of water) to pre-heat the incoming water and also to recycle the water for its best utilization.

Steam-turbine receives controlled steam from boiler and converts its energy into mechanical energy which drives the 3-ph a. c. generator (=alternator). The alternator delivers electrical energy, at its rated voltage (which may be between 11 to 30 kV). Through a circuit breaker, the step up transformer is supplied. Considering the bulk-power to be transmitted over long distances, the secondary rating

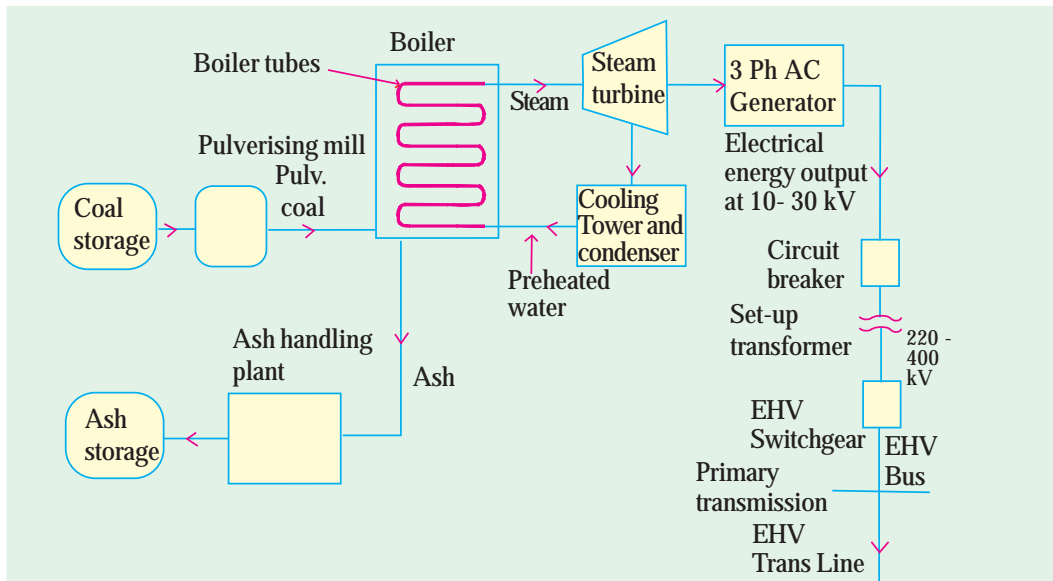

Fig. 24.1. Schematic Diagram of a Coal-fired Thermal Station

of this transformer may be 220 or 400 kV (as per figures for India). Through Extra-High Voltage Switch gear, the Bus is energized and the EHV primary transmission line can transport power to the Load centres connected to it.

A modern coal-fired thermal power station consumes about 10 % of its power for supplying to the Auxiliaries. These are mainly as follows.

- (a) Main-exciter for alternator.
- (b) Water pumps.
- (c) Fans: Forced draught and Induced draught fans for Pre-heaters and Chimney.
- (d) Coal handling plant including pulverising mill.
- (e) Ash handling plant including Electrolytic Precipitator.

Naturally, whenever such a station is to be brought into operation (either at commissioning or after repairs/maintenance schedule) the power required for the auxiliaries has to be supplied by the grid. Once the system is energized fully, it will look after supplying power to its own auxiliaries.

### Merits of Coal-fired thermal stations

1. Fuel (=coal) is cheap.
2. Less initial cost is required.
3. It requires less space.
4. As a combination of all above points, the cost of generating unit of electrical energy is less.

**Demerits**

1. Atmospheric pollution is considerable.
2. Coal may have to be transported over long distances, in some cases, after some years, and then the energy cost may be quite high.

**24.5.2. Nuclear Power Stations**

Nuclear energy is available as a result of fission reaction. In a typical system, Uranium 235 is bombarded with neutrons and Heat energy is released. In chain-reaction, these release more neutrons, since more Uranium 235 atoms are fissioned. Speeds of Neutrons must be reduced to critical speeds for the chain reaction to take place. Moderators (= speed-reducing agents like graphite, heavy water, etc). are used for this purpose. Nuclear fuel rods (of Uranium 235) must be embedded in speed-reducing agents. Further, control rods (made of cadmium) are required since they are strong neutron-absorbers and help in finely regulating this reaction so that power control of the generator is precisely obtainable. When control rods are pulled out and are away from fuel rods, intensity of chain reaction increases, which increases the power output of the system. While if they are pushed in and closer to the fuel rods, the power-output decreases. Thus, the electrical load demand on the generator decides (automatically) the control-rod positions through a very sophisticated control system.

Fig. 24.2 shows a basic scheme of such a Nuclear power-station.

**Advantages of Nuclear Generation**

1. Quantity of fuel required is small for generating a given amount of electrical energy, compared to that with other fuels.
2. It is more reliable, cheaper for running cost, and is efficient when operated at rated capacity.

**Disadvantages**

1. Fuel is expensive and not abundantly available everywhere.
2. It has high capital cost.
3. Maintenance charges are high.
4. Nuclear waste disposal is a problem.

Fig. 24.2. Schematic Diagram of a Nuclear Power Station indicating Main Components

**24.5.3. Hydroelectric Generation**

Water-reservoir at higher altitudes is a pre-requisite for this purpose. Power-house is located at a lower level. The difference in these two levels is known as "Head."

Based on the "Heads", the Hydroelectric stations are categorized below:

1. Low head up to 60 metres.
2. Medium head between 60 and 300 metres.
3. High heads above 300 metres.

In this method of generation, water from higher height is passed through penstock as controlled in the valve-house, into the water turbine. Thus, potential energy of water stored at higher altitudes is first converted into Kinetic energy. As the water reaches the turbine, it gains speed after losing the Potential energy. Kinetic energy of this speedy water drives the water turbine, which converts this into mechanical output. It drives the coupled generator, which gives Electrical energy output.

A schematic diagram of such a system is shown in fig.

The valve house has a controlling valve (=main sluice valve) and a protecting valve (= an automatic, isolating, “butterfly” type valve). As is obvious, power control is done by the main sluice valve, while “butterfly” valve comes into action if water flows in opposite direction as a result of a sudden drop in load on the generator. Otherwise, the penstock is subjected to extreme strains and it has a tendency to burst due to pressure of water as a result of sudden load reduction.

Fig. 24.3. Schematic of a typical Hydroelectric station

**Note:** Variation of Head (low-, medium-, or high-head) will affect the block-schematic

After doing the work (of imparting its energy to the water turbine), the water is allowed to pass into the tail-race reservoir.

The water turbines are essentially low-speed prime movers. In that, the best operating speed is dependent on the head. Alternators coupled to water turbines thus have large number of poles (since  $P = 120 f/N$ ). Such alternators have the Salient-Pole type rotor.

There are different types of water turbines suitable for different cases (i.e. Heads, Power rating, Load-variation curve, etc). Since, this is only an elementary treatment, these aspects will not be discussed here.

## 24.6. Non-Conventional Energy Sources

Considering the previously discussed thermal methods of conventional energy-generations, it is necessary to understand the non-conventional energy sources, since they have two points in their favour.

- (a) Non-polluting processes are used.
- (b) Perpetuity and renewability of the main source (which is a natural atmospheric resource) generally exists.

The non-conventional energy sources are further advantageous due to virtually zero running cost, since wind energy or solar energy is the input-source of power.

However, they are disadvantageous due to high initial cost (per MW of installed capacity) and due to uncertainty resulting out of weather changes. For example, dense clouds (or night hours) lead to non-availability of solar energy. Similarly, “still-air” condition means no possibility of wind power generation, and during stormy weathers, wind turbines cannot be kept in operation (due to dangerously high speeds they would attain if kept in operation).

### 24.6.1. Photo Voltaic Cells (P.V. Cells or SOLAR Cells)

When ionized solar radiation is incident on a semi-conductor diode, energy conversion can take place with a voltage of 0.5 to 1 volt (d.c.) and a current density of 20-40 mA/cm<sup>2</sup>, depending on the

Fig. 24.4. Photo Voltaic (or Solar Cell)

materials used and the conditions of Sunlight. Area of these solar cells decides the current output. An array of large number of such diodes (i.e. Solar cells) results into higher d.c. output voltage.

Since, the final form of electrical energy required is generally an alternating current, it is realized from d.c. using inverters.

At quite a few locations in India, for realizing few hundred kilowatts of power-rating, huge arrays are accommodated in horizontal as well as vertical stacks, so that land area required is not too vast. Electrically, they are connected in series and in parallel

combinations of cells so that rated voltage and current are realized.

Just to understand the principle of operation of solar cells, let a semi-conductor diode receive ionized radiation from Sun, as in fig. 24.4.

Typical materials used for these cells are: material doped with boron, cadmium sulphide, gallium-arsenide, etc. Their choice is mainly decided by conversion efficiency. Best material may lead to the efficiency being typically 15%. Since solar energy is available free of cost, this low-efficiency does not matter.

This method suffers from the disadvantages of having high initial cost and uncertainty (since dependent on weather conditions) including non operative night periods. Main advantages are: **(i)** no running cost (however, replacements of components may be a botheration), **(ii)** no pollution, **(iii)** location can be near the load (hence transportation of power is not required over long distances), **(iv)** since natural source is involved, it is perpetual.

Individual stations using solar cells are in operation with ratings of the order of 250-1000 kW. With manufacturing costs of semi-conductor devices going down and with the advent of better and better quality of cells which will be available in future, this method of generation has bright prospects.

## 24.6.2. Fuel Cells

### 24.6.2.1. Principle of Operation

In Fuel cells, negative porous electrode is fed by hydrogen and the positive porous electrode is fed by oxygen. Both the electrodes are immersed in an electrolyte. The porous electrodes are made of such a conducting material that both the fuel (oxygen and hydrogen) and the electrolyte can pass through them. Such a material for electrodes is nickel. The electrolyte is a solution of sulphuric acid or potassium hydroxide. The electrodes have a catalyst (= platinum or sintered nickel) which break the fuel compound into more reactive atoms.

### 24.6.2.2. Chemical Process (with Acidic Electrolyte)

These hydrogen ions enter the solution (=electrolyte) leaving behind electrons which pass through external circuit to the positive electrode.

Thus, the combination of Hydrogen and Oxygen results into water at the positive electrode. Water is the waste-product of the cell, which is harmless. The process is, thus, pollution free. There is no source of energy required, since the process is basically “**chemical**” in nature.

### 24.6.2.3. Schematic Diagram.

It is given in fig 24.5

Fig. 24.5. Fuel Cell

### 24.6.2.4. Array for Large outputs

A fuel cell has a d. c. output voltage typically of 1.23 volts at normal atmospheric pressure and temperature. Raising pressure and temperature increases this voltage. To realize large output parameters (= voltage, current, and hence power), an array of a large number of fuel cells (connected in series as well as in parallel) is made. Voltage levels of 100 to 1000 V and power levels in kilowatts can be realized.

### 24.6.2.5. High Lights

1. Pollution-free, noiseless.
2. No outside source of energy is required.
3. Efficient.
4. No restriction on location
  - (a) High initial cost.
  - (b) Working life is short.

**Note:** Solar energy can also be used for generating electrical energy through an intermediate stage of producing steam, which is used later for driving an alternator. However, this method is not discussed here.

## 24.6.3. Wind Power

### 24.6.3.1. Background

Wind power has been in use for serving the mankind, since centuries through what has been popularly known as “Wind-mills.” There is no “electrical” stage of energy in old-styled uses where wind-velocity is directly used for performing the jobs such as wheat-grinding, pumping water for irrigation, sailing vessels, etc. It enjoys the advantages of being plentiful, inexhaustible, renewable and non-polluting, over and above being cheap for running costs. It suffers from disadvantages of being unreliable, and being economically un-viable for large power generation. In India, a large number of such units with small and medium power ratings (up to 100 kW) are already in operation mainly in coastal or hilly areas. With the modern system, it is now preferred to have suitable power-control circuits on the output side of wind-generators so that these can pump energy into low voltage lines of the grid over a wide range of variation of wind speeds.

### 24.6.3.2. Basic Scheme

A large variety of wind-turbines naturally exist arising out of large variation in wind-pattern

Fig. 24.6 (a) . Wind-generation, a Schematic view

Fig. 24.6 (b). Part-side-view to show a typical three bladed wind turbine

all over and out of different manufacturers producing systems with different designs. Since the aim here is to understand the basic system, only one type of system is presented here.

In Fig. 24.6 (a) an arrangement wherein, a horizontal three-bladed system is shown mounted on a tower. Through rotation-transformation using gears to step up the speed and to link the horizontal axis of turbine with vertical axis of generator.

The speed of wind varies, as such turbine speed also varies so that output frequency and voltage of three-phase alternator vary over a wide range. Further, its waveform is also a distorted one. To increase its utility, it is necessary to modulate (through proper power-control) to derive line-frequency constant voltage output and hook-up to local grid for pumping the available wind-energy into it. This is schematically represented in fig 24.7.

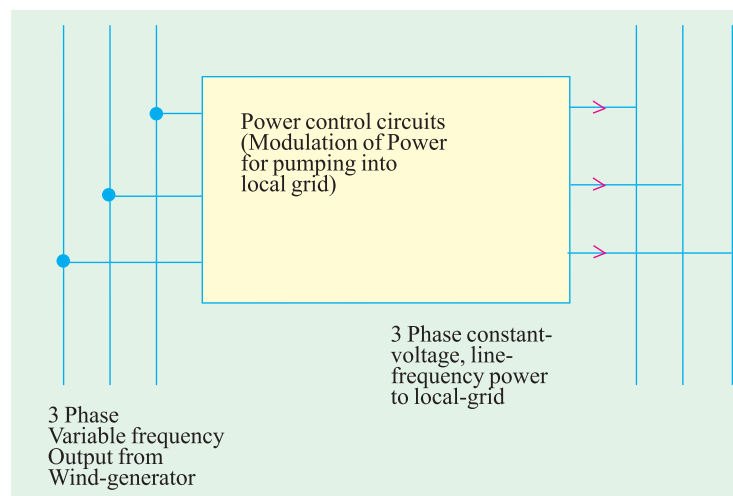

Fig. 24.7

### 24.6.3.3. Indian Scenario

Wind farms have been located where a large number of wind generators of ratings of few hundred kilowatts are in operation. For every unit, there is a safe wind - speed zone. If the wind-speed is below this, there is no appreciable power output, hence, it is better that the system is *not* brought into operation. If the wind speeds are too high, it is mechanically unsafe and hence it is *not* to be operated, even if the energy available is higher. This is decided by automated system. Such forms are located in coastal regions and in hilly areas. Because of the metering of energy received by the local grid, the investor can get a good return through payment from the grid-authorities. Hence, this has become a medium-level and attractive industrial investment.

# CHAPTER 25

## Learning Objectives

- Introduction
- Salient aspects of conversions
- Energy-balance
- Magnetic-field system: Energy and Co-energy
- Linear System
- A Simple Electro-mechanical System
- In terms of Field Energy
- In terms of field Co-energy
- Energy in terms of Electrical parameters
- Rotary Motion
- Description of Simple System
- Energy stored in the coils
- Different Categories
- One coil each on Stator and on Rotor
- Vital Role of Air-gap
- Statically induced emf and Dynamically induced emf.

## **ELEMENTS OF ELECTRO- MECHANICAL ENERGY CONVERSION**

An electric motor is a machine which converts electrical energy into mechanical (rotational or kinetic) energy

### 25.1. Introduction

“Energy can *neither* be created *nor* be destroyed”. We can only change its forms, using appropriate energy-conversion processes.

An interesting aspect about the energy in “Electrical form” is that neither it is so available *directly from nature* nor it is required to be finally consumed in that form. Still, it is the most popular form of Energy, since it can be transported at remote Load-locations, for optimum utilization of resources. Further, technological progress has now made it possible to devise Electrical-Power-modulation systems so flexible and controllable that modern systems tend to be energy-efficient, with increase in life-span of main equipment and the associated auxiliary components (like switches, connecting cables, contactors, etc.) since it is now

Generator

possible to avoid overstrain (= over-currents or over-voltage) on the system. This means a lot for the total production process (for which electrical energy is being used) since the quality of the production improves, and plant-maintenance is minimal. Energy-conversion systems then assume still higher importance.

Energy conversion takes place between well known pairs of forms of Energy: Electrical ↔ Chemical, Electrical ↔ Thermal, Electrical ↔ Optical, Electrical ↔ Sound, and Electrical ↔ Mechanical are the common forms with numerous varieties of engineering - applications. Electrical ↔ mechanical conversion is the focus of discussion in this chapter.

The elements of electro-mechanical energy conversion shall deal with basic principles and systems dealing with this aspect. Purpose of the study is to have a general approach to understand to design, and later to modify the system with the help of modern technologies, for overall improvisation.

It is necessary to be aware about:

- (a) basic conditions to be fulfilled by the conversion system.
- (b) methods for innovating the conversion systems.

Electromechanical energy-conversion finds applications in following categories of systems:

- (a) transducers: Devices for obtaining signals for measurement / control,
- (b) force-producing devices: Solenoid-actuators, relays, electromagnets,
- (c) devices for continuous-energy-conversion: Motors / Generators

These systems have different configurations. But the principles of their working are common. Understanding these principles enables us to analyze / design / improvise / innovate such systems. As a result of such development, newer types of motors and the associated modern power controllers have recently been manufactured and become popular. Controllers using power-

electronics switching devices offer energy-efficient, user-friendly, and high-performance drives. Their initial investment may be larger but two important parameters justify their use: *(i)* Considerable energy is saved, resulting into payback periods as short as 18-24 months, *(ii)* The controllers ensure to limit the currents to pre-set values under conditions of starting /overload/ unbalanced supply. Hence, the entire system enjoys longer life. Both these effects lead to better production-process and hence these are readily acceptable by industries.

## 25.2 Salient Aspects of Conversions

Purpose of electro-mechanical conversion device is to change the form of energy. Here, for simpler discussion, only rotary systems will be dealt with. When it is converting mechanical input to electrical output the device is “generating”. With electrical input, when mechanical output is obtained, the device is motoring.

Some simple aspects of an electrical machine (motor / generator) have to be noted at this place:

- (1) Electrical machine has a Stator, a Rotor, and an air-gap in between the two. For a flux path, the magnetic circuit has these three parts in series. In general, magnetic poles are established in Stator and in Rotor.
- (2) Magnetic effects of following types can be categorized:
  - (a) **Electromagnetic:** Due to currents passed through windings on Stator and / or Rotor, producing certain number of poles on these members.
  - (b) **Permanent Magnets:** One side (Stator or Rotor) can have permanent magnets.
  - (c) **Reluctance variation:** Surface of Rotor near the air-gap can be suitably shaped to have a particular pattern of Reluctance-variation so as to control the machine behaviour as per requirements.
- (3) Basic conditions which must be satisfied by such devices are:
  - (a) Equal number of poles must be created on the two sides.
  - (b) In some cases, reluctance-variation is primarily used for machine-action. The Stator side must accommodate a winding carrying current for the electromagnetic effect, when rotor surface is shaped so as to have the desired pattern of reluctance variation. Or, non-cylindrical rotor cannot have the current -carrying winding for machine action.
- (4) Out of stator, rotor and air-gap, maximum energy-storage at any angular position takes place in the air-gap, since its reluctance is highest out of the three members.
- (5) Stored energy must depend on rotor-position and the device tends to occupy that angular position which corresponds to maximum stored energy. If this position varies as a function of time, the device produces continuous torque.
- (6) Ideal output of a motor is a constant unidirectional torque with given currents through its windings. In some cases, the output torque (as a compromise) is an average value of a cyclically varying torque.
- (7) Where current-switching is done for motor-control, as in modern controllers, instantaneous effect has to be understood to conclude on any of the points mentioned above.
- (8) A device can work either as a generator or as a motor, provided pertinent conditions are satisfied for the concerned mode of operation.

Stator and Rotor

### 25.3. Energy – Balance

For an electro-mechanical system, following terms are important:

- (i) Electrical port (= armature terminals): receiving / delivering electrical energy.
- (ii) Mechanical port (= shaft): delivering / receiving mechanical energy.
- (iii) Coupling field: Magnetic field *or* Electric field.

Even though, theoretically, both the types of fields mentioned above are able to convert the energy, the magnetic medium is most popular since the voltage levels required are not very high, and the devices of given power rating are smaller in size and are economical. Hence, only those will be dealt with.

It is obvious that an electrical motor receives energy at the electrical port and delivers it at the mechanical port. While an electric generator receives the energy at the mechanical port and delivers it at the electrical port. It is also known

that the following losses take place in such systems and are dissipated away as heat: (i)  $i^2r$  losses in the windings of the machines, (ii) friction and windage losses, (iii) core-losses.

These can be either neglected or attached to electrical port, mechanical port and coupling magnetic field respectively, for simpler analysis. With this, the simple energy balance equation can be written as:

Change in Electrical Energy = Change in Mechanical Energy + Change in Field-Energy

$$dW_{elec} = dW_{mech} + dW_{fld} \quad \dots (25.1)$$

It is natural that this equation has +ve signs for electrical and mechanical-energy-terms when the device is motoring. For generating mode, however, both the terms assume –ve signs.

In case no mechanical work is done, eqn. (25.1) reduces to eqn. (25.2) below indicating that Electrical energy - input is stored in the magnetic field.

$$dW_{elec} = dW_{fld} \quad \dots (25.2)$$

### 25.4. Magnetic-field System: Energy and Co-energy

#### 25.4.1 Linear System

Fig. 25.1 (a) Magnetic circuit

Conversion of electrical energy into mechanical energy

Fig. 25.1 (b) Characteristic of a magnetic circuit

Fig. 25.1 (c) Energy and co-energy

A simple magnetic circuit is shown in Fig 25.1 (a), with assumptions that air-gap length at the joints is negligible, and the magnetic medium is not saturated. With  $A$  as the cross-sectional area of the core and  $L_m$  as the mean length of the path, a coil with  $N$  turns carrying a current of  $i$  amp has an mmf of  $F$ , establishing a flux of  $\phi$ , related by

$$\phi = F \times \rho_m$$

where  $\rho_m$  = Permeance of the Magnetic circuit

$$= \mu_o \mu_r A / L_m$$

with  $\mu_r$  = relative permeability of the magnetic medium,

This corresponds to the following relationships:

Coil Inductance,  $L = N^2 \rho_m = N\phi / i = \lambda / i$

where  $\lambda$  = flux-linkage of the coil, in weber-turns

$$W_{fld} = \text{Energy stored in the coil} = \frac{1}{2} Li^2 = \frac{1}{2} N^2 \rho_m i^2 = \frac{1}{2} F^2 \rho_m$$

$$= \frac{1}{2} F(F\rho_m) = \frac{1}{2} F\phi \quad \dots (25.3)$$

In this eqn.,  $\rho_m$  is the slope of the characteristic in Fig 25.1 (b). Hence, the inductance is proportional to the slope of  $F$ - $\phi$  plot. In Fig., 25.1 (b), for the operating point  $A$ , the mmf is  $F_1$  and the flux  $\phi_1$ . At the point  $A$ , the energy stored in the field is given by eqn. below:

$$W_{fld} = \frac{1}{2} F_1 \phi_1$$

$F_1$  is due to the current  $i_1$ .  $W_{fld}$  is given by area  $OATO$  in Fig 25.1(b).

In Fig 25.1(b), the origin refers to the system without magnetization.

The system can reach the point  $A$ , starting from  $O$  as the current in the coil is increased from  $O$  to  $i_1$ .

Let us understand the intermediate events.

At point  $B$ , the flux is  $\phi$  due to the mmf  $F$ .

An increment in coil current results into increase in mmf by  $dF$ . This increases the core-flux by  $d\phi$ . New operating point is  $C$ .

Eqn. (25.3) is to be suitably re-written in terms of these incremental values.

$$W_{fld} = \int dW_{fld} = \int_0^{\phi_1} Fd\phi = \int_0^{\phi_1} (\text{area of the strip } NBB'Q) = \text{area of triangle } OAT$$

$$= (1/\rho_m) \int_0^{\phi_1} \phi \cdot d\phi = \frac{1}{2} \phi_1 \cdot F_1 \quad \dots (25.4)$$

Alternatively, we have the area of elemental strip  $kBB''M = \phi \cdot dF$

$$\begin{aligned} \text{Area of } \Delta OAS &= \int_0^{F_1} \phi \cdot dF \quad (\text{area of the strip } KBB''M) \\ &= \int_0^{F_1} \phi \cdot dF = \mathcal{O}_m \int_0^{F_1} F \, dF = \mathcal{O}_m \frac{F_1^2}{2} = \frac{1}{2} F_1 \phi_1 \quad \dots (25.5) \end{aligned}$$

In order to distinguish with respect to the terms in eqn. (25.4), this area is called as the “Co-energy of the field” and is represented by  $W'_{fld}$ . For a Linear system, however, for a given operating point, say A, the two energy-terms are equal. Hence,

$$W_{fld} = W'_{fld} = \frac{1}{2} F_1 \phi_1 = \frac{1}{2} Li_1^2 \quad \dots (25.6)$$

In order to have a simple and clear distinction between the two energy terms, it can be said that the differential variable “**Current**” (or mmf) is related to Co-energy and the differential variable “flux - linkage” (or flux) is related to Energy.

This energy stored in the magnetic field comes from the electrical source connected to the coil in Fig. 25.1(a).

### 25.4.2. A Simple Electromechanical System

A simple electro-mechanical system is shown in Fig. 25.2(a).

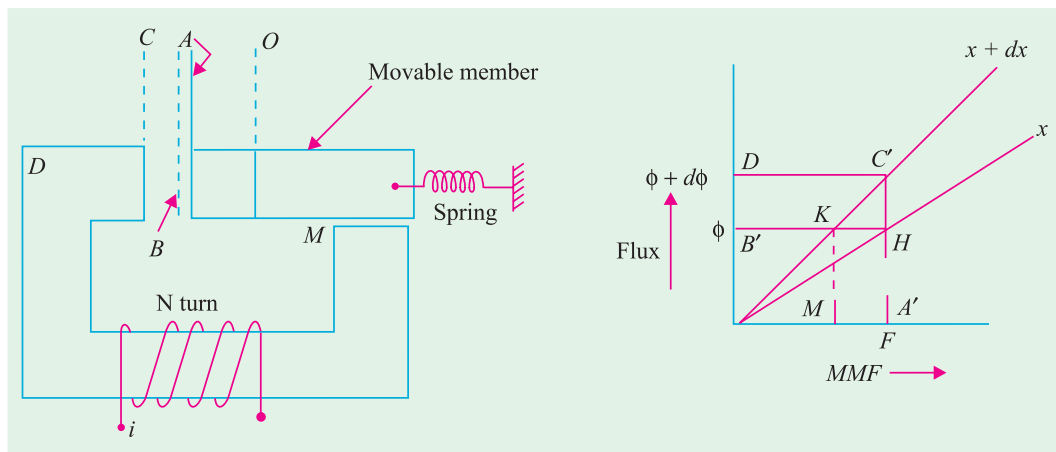

Fig. 25.2 (a)

Fig. 25.2 (b)

Reference point  $O$  corresponds to the unstretched spring. Energy stored in the spring is then Zero. In position  $A$  of the movable member, the spring is elongated by  $x$ , and the corresponding energy stored in the spring is  $\frac{1}{2} K_s x^2$ , where  $K_s$  is “spring-constant” of the linear system in  $Nw / m$ . In Fig 25.2 (a), the distance  $OA$  is  $x$ . The elemental distance  $AB$  is  $dx$ , so that  $OB$  is  $x + dx$ . For simpler analysis, it is assumed that magnetic material is highly permeable and that the clearance at point  $M$  (for movement of the member) is negligible. So that the mmf of the coil is required to drive the flux in the region  $OABC$  only. The flux-mmf

A simple electro-mechanical system

relationships are plotted for these two positions in Fig 25.2 (b). In position A, the movable member has moved a distance of  $x$  from its unstretched position or reference point. Let the operating point be  $H$ , so that the coil-mmfmf  $OA (=F)$  establishes a flux  $OB (=ϕ)$ . In this position, the movable member experiences a force in such a direction that the energy stored in the field tends to increase. It tends to reach  $B$ , so that an additional displacement of  $dx$  shifts the characteristic upwards and final operating point in position  $B$  is  $C'$ . From  $H$  to  $C'$ , the operating point can move in any one of the following ways:

(a)  $HC'$  vertically, if the mechanical movement is too slow so that change of flux is slow and induced emf in the coil is negligible. This corresponds to the coil-mmfmf remaining constant at  $F$  during the transition. Constant mmfmf means vertical travel of the operating point from  $H$  to  $C'$ .

(b)  $H$  to  $K$  horizontally and then  $K$  to  $C'$  along the characteristic corresponding to  $(x + dx)$  as the displacement of the movable part. This is possible when the motion is very fast, resulting into flux remaining constant till the operating point traverses from  $H$  to  $K$ . Then, from  $K$  to  $C'$ , the flux increases, an emf is induced in the coil and the mmfmf finally reaches its value of  $F$ , at the point  $C'$ .

(c) In reality, the transition from  $H$  to  $C'$  will be somewhere in between these two extremes mentioned above.

However, for simplicity, one of these extreme conditions has to be accepted. In (a) above, the mmfmf remains constant. In (b) above, the flux (and hence the flux-linkage) remains constant. Let us take the case of constant-mmfmf. If the process has taken a time of  $dt$ ,

$$\begin{aligned} \text{Electrical-energy input during the process} &= dW_{\text{elec}} \\ &= (\text{voltage applied to the coil}) \times \text{current} \times dt = e idt \\ &= d\lambda / dt \times i \times dt = id\lambda = i N d\phi = F d\phi = \text{area of rectangle } B'HC'D \end{aligned}$$

In this case, coil-resistance has been neglected.

### 25.4.2.1. In terms of Field Energy

At the previous operating point  $H$ , the energy stored in the magnetic field,

$$W_{\text{fld1}} = \text{area of } \Delta OHB'$$

At the new position corresponding to the operating point  $C'$ , the field energy stored is given

by  $W_{\text{fld2}} = \text{area of the } \Delta OC'D$

The difference of these two is the change in the energy stored in the

$$\begin{aligned} \text{magnetic field} \quad &= dW_{\text{fld}} = \frac{1}{2} [OA' \times A'C' - OA' \times A'H] \\ &= \frac{1}{2} OA' [A'C' \times A'H] = \frac{1}{2} OA' HC' \\ &= \frac{1}{2} \cdot F \cdot d\phi = \frac{1}{2} dW_{\text{elec}} \end{aligned}$$

Out of the energy delivered by the source, half is stored in the magnetic field. Where has the remaining half been utilized? Obviously, this must have been transformed into the mechanical work done. In this case, neglecting losses, it is finally stored in the stretched spring due to its elongation by  $dx$ .

Comparing this with the equation (25.1),

$$\begin{aligned} dW_{\text{elec}} &= dW_{\text{mech}} + dW_{\text{fld}} \\ &= dW_{\text{mech}} + \frac{1}{2} dW_{\text{elec}} \end{aligned}$$

or  $dW_{\text{mech}} = dW_{\text{fld}} = \frac{1}{2} dW_{\text{elec}}$

Consider that a force  $F$  is operative at the displacement of  $x$ . This force is in such a direction that  $x$  increases or the movable member is attracted towards  $D$ . In the same direction, a

displacement by  $dx$  results into the increase in the energy stored by the spring. Relating the concerned terms,

$$\begin{aligned}
 & F = k_s \cdot x \\
 dW_{\text{mech}} &= \text{mechanical work done against the force of the stretched spring} \\
 &= -F dx = dW_{\text{fld}} \\
 \text{or } F &= -dW_{\text{fld}}/dx, \text{ in this case} \\
 &= -\delta W_{\text{fld}}/\delta x, \text{ in general}
 \end{aligned}$$

Alternatively, the difference in the energy stored in the spring also gives a very useful relationship.

In the position corresponding to  $x + dx$ , the energy stored in the spring =  $\frac{1}{2} k_s (x + dx)^2$ . Similarly, at  $x$ , the energy =  $\frac{1}{2} k_s x^2$

$$\begin{aligned}
 \text{Difference} &= \frac{1}{2} k_s [(x + dx)^2 - (x)^2] \\
 &= \frac{1}{2} k_s [x^2 + 2 \cdot x \cdot dx + (dx)^2 - x^2] \\
 &= \frac{1}{2} k_s [2 \cdot x \cdot dx], \text{ neglecting } (dx)^2 \\
 &= k_s \cdot x \cdot dx = F dx
 \end{aligned}$$

This difference is nothing but  $dW_{\text{mech}}$ , which is equal in magnitude to  $dW_{\text{fld}}$  and confirms the relationship obtained earlier.

#### 25.4.2.2. In terms of field Co-energy

Proceeding along lines similar to those while dealing with field-energy above, following relationships exist. For simpler discussion, the transition is assumed to be along  $HKC'$ . Neglecting area of the small triangle  $HKC'$ , we have

$$\begin{aligned}
 \text{at } x, W'_{\text{fld1}} &= \text{area of } \Delta OA'H \\
 \text{at } x + dx, W'_{\text{fld2}} &= \text{area of } \Delta OA'C' \text{ (neglecting } \Delta HKC') \\
 dW'_{\text{fld}} &= W'_{\text{fld2}} - W'_{\text{fld1}} = \phi \cdot dF \text{ where } dF = MA' \\
 &= \text{Co-energy in the field } F dx
 \end{aligned}$$

$$\begin{aligned}
 \text{Hence, } F &= + dW'_{\text{fld}}/dx, \text{ in this case} \\
 &= + \delta W'_{\text{fld}}/\delta x, \text{ in general}
 \end{aligned}$$

### 25.5. Energy in Terms of Electrical Parameters

In the preceding article, the energy and force were related in terms of magnetic-system parameters, namely flux and mmf, through the third parameter, the permeance.

It is at times convenient to relate these things in terms of electrical-system-parameters, namely, the inductances and currents. That is being dealt with here only for linear systems. Let  $\rho$  be the permeance of the magnetic circuit and  $L$  be the coil-inductance.

$$\begin{aligned}
 W_{\text{fld}} = \text{Field-energy} &= \frac{1}{2} F \phi = \frac{1}{2} Ni (Ni \rho) = \frac{1}{2} (N^2 \rho) i^2 \\
 &= \frac{1}{2} Li^2 \\
 F &= -dW_{\text{fld}}/dx = -\frac{1}{2} \cdot i^2 \cdot dL/dx
 \end{aligned}$$

Thus, a force exists if the coil-inductance is dependent on  $x$ . Such analysis is more suitable when the system has more than one coils coupled through the magnetic circuit. If two such coils are considered, following data should be known for evaluation of the force, in case of linear displacement:

$$\begin{aligned}
 L_{11} &= \text{self inductance of coil - 1} \\
 L_{22} &= \text{self inductance of coil - 2}
 \end{aligned}$$

$L_{12}$  = Mutual inductance between two coils, 1 and 2

$i_1, i_2$  = currents through the two coils.

$W_{fld}$  = Total energy stored in the field =  $\frac{1}{2} L_{11} i_1^2 + \frac{1}{2} L_{22} i_2^2 + L_{12} i_1 i_2$

Magnitude of Force,  $F = dW_{fld}/dx = \frac{1}{2} i_1^2 dL_{11}/dx + \frac{1}{2} i_2^2 dL_{22}/dx + i_1 i_2 dL_{12}/dx$

From the right-hand side of this equation, it is noted that the inductance-term which is dependent on  $x$  contributes to the force.

### 25.6. Rotary Motion

Most popular systems for electro-mechanical energy are Generators and Motors. The preceding discussion dealt with the Linear motions, wherein  $x$  represented the displacement parameter, and force was being calculated.

Now we shall deal with the rotary systems, wherein angular displacement parameters (such as  $\theta$ ) and corresponding torque developed by the system will be correlated, through a systematic procedure for a typical rotary machine.

Rotary motion

#### 25.6.1. Description of Simple System

A simple rotary system has a 'stator' and a 'rotor'. Air-gap separates these two. Stator has two similar coils 'a' and 'b' located at  $90^\circ$  electrical, with respect to each other. Inner surface of the stator is cylindrical. Outer surface of the rotor is also cylindrical resulting into uniform air-gap length for the machine.

The diagram represents a two-pole machine. Axis of coil 'a' may be taken as reference, with respect to which the rotor-coil axis makes an angle of  $\theta$ , at a particular instant of time. For a continuous rotation of the rotor at  $\omega$  radians / sec,  $\theta = \omega t$ . Coil-'b'-axis is perpendicular to the reference, as shown. Due to the uniform air-gap length, and due to the perpendicularity between coils 'a' and 'b', inductance-parameters exhibit the following patterns:

Fig. 25.3. Simple rotary system

Let  $x$  represents the inductance parameter as a function of  $\theta$ . The subscripts indicate the particular parameter.  $x_{aa}$  = self-inductance of coil 'a',  $x_{ab}$  = mutual inductance between coils a and b and so on.  $x$  represents value of the particular inductance parameter, which will help in knowing the variation of inductance with  $\theta$ .

(a) Self inductances of coils 'a' and 'b' are not dependent on rotor position.

$$x_{aa} = L_{aa} \text{ and } x_{bb} = L_{bb}, \text{ at all values of } \theta.$$

(b) Mutual inductance between stator coils 'a' and 'b' is zero, due to perpendicularity.

$$x_{ab} = \text{zero, for all values of } \theta.$$

(c) Self-inductance of rotor-coil is constant and not dependent on  $\theta$ .

$$x_{ra} = L_{rr} \text{ (= constant), at all values of } \theta.$$

(d) When 'r' and 'a' coils have their axes aligned, at  $\theta = 0$ , the mutual inductance between them is maximum, which is denoted by  $x_{ar}$ . At  $\theta = 90^\circ$ , their axes are perpendicular resulting into no coupling or zero mutual inductance. When  $\theta = 180^\circ$ , r and a coils are aligned in anti-parallel way and hence maximum mutual inductance exists between them with negative sign.

Further, whatever happens to coupling between r and a at a value of  $\theta$  happens to that between r and b with a delay of  $90^\circ$ . All these are mathematically represented as :

$$\begin{aligned} x_{ra} &= L_{ra} \cos \theta = L_{ra} \cos(\omega_r t) \\ x_{rb} &= L_{ra} \sin \theta = L_{ra} \sin(\omega_r t) = L_{ra} \cos(\omega_r t - 90^\circ) \end{aligned}$$

Since 'a' and 'b' coils are alike, the maximum mutual inductance is represented by the same term  $L_{ra}$ .

### 25.6.2. Energy stored in the coils

Energy stored in the magnetic field can either be expressed in terms of mmf and flux or be expressed in terms of inductance-terms and coil currents. If  $i_a$ ,  $i_b$  and  $i_r$  are the coil-currents, stored-energy-terms are as given below:

(i)  $W_1 =$  Energy in Self-ind. of coil 'a':  $\frac{1}{2} L_{aa} i_a^2$

(ii)  $W_2 =$  Energy in Self-ind. of coil 'b':  $\frac{1}{2} L_{bb} i_b^2$

(iii)  $W_3 =$  Energy in Self-ind. of coil 'r':  $\frac{1}{2} L_{rr} i_r^2$

(iv)  $W_4 =$  Energy in mutual inductance between 'a' and 'r':  $x_{ra} i_r i_a = x_{ra} i_r i_a = x_{ra} \cos \theta \cdot i_r \cdot i_a$

(v)  $W_5 =$  Energy in mutual inductance between 'b' and 'r':  $x_{rb} i_r \cdot i_b = x_{ra} \sin \theta \cdot i_r \cdot i_b$

$W =$  Total energy stored in the system = Sum of all the energy-terms cited above

$$= W_1 + W_2 + W_3 + W_4 + W_5$$

$T =$  Torque produced =  $\delta W / \delta \theta$

If  $i_a$ ,  $i_b$ ,  $i_r$  are assumed to be constant currents, for simplicity, so that their derivatives with respect to  $\theta$  (and hence with respect to time  $t$ ) are zero, the energy-terms which include constant inductances do not contribute to torque.  $W_1$ ,  $W_2$ , and  $W_3$  thus cannot contribute to torque.  $W_4$  and  $W_5$  contribute to torque related by:

$$\begin{aligned} T &= \delta W / \delta \theta = \delta / \delta \theta [W_4 + W_5] = \delta / \delta \theta [L_{ra} i_r i_a \cos \theta + L_{ra} i_r i_b \sin \theta] \\ &= L_{ra} i_r [-i_a \sin \theta + i_b \cos \theta] \end{aligned}$$

$$\text{If } i_a = i_b = i_s, T = L_{ra} i_r i_s [-\sin \theta + \cos \theta]$$

For such a system, the torque is zero at  $\theta = +45^\circ$ , and the torque is maximum at  $\theta = -45^\circ$ .

If one of the stator currents is reversed, the result differs. For this, let  $i_a = -i_s$  and  $i_b = +i_s$

$$T = L_{ra} i_r i_s [\sin \theta + \cos \theta]$$

And the maximum torque occurs at  $\theta = 45^\circ$ . This is a position for rotor, which is midway between the two stator coils.

25.6.2.1. Different Categories

From the torque expressions above, it is clear that the torque exists only when stator and rotor-coils carry currents. When only stator-coils (or only rotor coil) carry current, torque cannot be produced.

(a) One coil each on Stator and on Rotor

In the above mentioned case, let us excite only one stator-coil. Let  $i_a = i_s$ ,  $i_b = 0$  and  $i_r$  maintained as before.

$$T = -L_{ra} i_r i_s \sin \theta$$

Following observations are made for such a case:

- (i) At  $\theta = 0$ ,  $T = 0$ , Mutual inductance  $x_{ra}$  is maximum ( $= L_{ra}$ ) and hence the stored energy in mutual inductance is maximum, but torque is zero.
- (ii) At  $\theta = 90^\circ$ ,  $T$  is maximum.  $x_{ra}$  is zero, hence the concerned stored energy is zero.
- (iii) As seen earlier,  $W_4 = L_{ra} i_r i_a \cos \theta = L_{ra} i_r i_s \cos \theta$

Torque =  $dW_4 / d\theta = i_r i_s d(L_{ra} \cos \theta) / d\theta$

Contributed by  $W_4$ , the power is related as follows:

Power = rate of change of energy with time  
 $= dW_4 / dt = dW_4 / d\theta \cdot d\theta / dt = T \cdot \omega_r = i_r i_s L_{ra} (-\sin \theta) \omega_r$

Magnitudes of these terms are maximum for  $\theta = 90^\circ$ . If  $\theta$  can be set at  $90^\circ$ , at all instants of time, torque obtained is maximum. Such a situation does exist in a d. c. machine in which rotor carries an armature winding which is a lap- or wave-connected commutator winding. The brushes are so placed on the commutator that rotor-coil-axis satisfies the above-mentioned condition of  $\theta = 90^\circ$ , irrespective of the rotor-position or rotor speed. Such an equivalence of a **rotating** armature coil with such an **effectively stationary** coil is referred to as a **quasi-stationary** coil. It means that a rotating coil is being analyzed as a stationary coil due to its typical behaviour for electro-mechanical energy conversion purposes.

Permanent magnet synchronous motor for washing machine

(b) Two stator coils carrying two-phase currents and rotor-coil carrying d. c.:

Permanent magnet

When two stator coils carry two-phase alternating currents, a synchronously rotating mmf is established. If the rotor-coil carries direct current, and the rotor is run at same synchronous speed, a unidirectional constant torque is developed. Mathematically, similar picture can be visualized, with a difference that the total system is imagined to rotate at synchronous speed. Such a machine is Synchronous machine, (to be discussed in Later chapters). It can be understood through the simple system described here.

(c) Machines with Permanent Magnets.

With suitable interpretation, the field side of the simple system can be imagined to be with permanent magnets in place of coil-excited electromagnets. All the interpretations made above are

valid, except for the difference that in this case there is no scope for controlling the rotor-coil-current-magnitude.

**(d) Machines with no rotor coil, but with premeance variation.**

Smooth cylindrical rotor surfaces do not exist in such cases. There are no rotor-coils. Due to geometry of the rotor surface, stator-coil- self inductances vary with rotor position. Thinking on lines of relating energy terms and their derivatives for torque-calculations, the working principles can be understood. With simple construction, Reluctance motors belong to this category.

**(e) Switched currents in Stator Coils.**

In yet another type, stator coils are distributed and properly grouped. One group carries currents during certain time interval. Then, this current is switched off. Another group carries current in the next time interval and so on. The rotor surface is so shaped that it responds to this current switching and torque is produced. Even though stator-coil-inductances are complicated functions of rotor position, the method of analysis for such machines is same. Prominent types of machines of this type are: switched reluctance motors, stepper motors, etc.

Current in stator coils

### 25.6.2.2. Vital Role of Air-gap

Magnetic circuit of an electrical machine has a flux established due to coil-mmfs. This flux is associated with stator core, rotor core and air-gap. An important point for understanding is to know which out of these three stores major portion of the field energy. Through an illustrative case, it will be clear below, in example 25.1.

**Example 25.1.** Let a machine with following data be considered.

Calculate the energy stored in the air-gap and compare the same with that stored in the cores.

- Stator-core outer diameter = 15 cm
- Stator-core inner diameter = 10.05 cm
- Rotor-core outer diameter = 10.00 cm
- Rotor-core inner diameter = 5 cm
- Axial length of the machine = 8 cm

Effect of slotting is neglected. The core volumes and air-gap volume for the machine shown in Fig 25.4 have to be calculated.

Fig. 25.4

**Solution.**

$$\text{Volume of Stator-core} = (\pi / 4) \times (15^2 - 10.05^2) \times 8 \text{ cm}^3 = 779 \text{ cm}^3$$

$$\text{Volume of Rotor-core} = (\pi / 4) \times (10^2 - 5^2) \times 8 \text{ cm}^3 = 471 \text{ cm}^3$$

$$\begin{aligned} \text{Volume of air-gap in the machine} &= (\pi / 4) \times (10.05^2 - 10^2) \times 8 \text{ cm}^3 \\ &= 6.3 \text{ cm}^3 \end{aligned}$$

Let the relative permeability of the core material be 1000. If the flux density is  $B$  Wb / m<sup>2</sup>, and  $\mu$  is the permeability, the energy-density is  $\frac{1}{2} \times B^2 / \mu$  Joules / m<sup>3</sup>. Let the flux density be 1.20 Wb / m<sup>2</sup>. Energy density in air-gap =  $\frac{1}{2} \times 1.20^2 / (4 \pi \times 10^{-7}) = 572350$  Joules / m<sup>3</sup>  
 = 0.573 Joules / cm<sup>3</sup>

Energy stored in air-gap =  $0.573 \times 6.3 = 3.6$  Joules

Energy-density in Magnetic medium =  $\frac{1}{2} \times 1.20^2 / (4\pi \times 10^{-7} \times 1000) = 573$  J / m<sup>3</sup>

It is assumed only for simplicity that the flux density is same for the entire core of stator and of rotor.

Energy stored in stator-core =  $573 \times 779 \times 10^{-6} = 0.45$  Joule

Energy stored in rotor-core =  $573 \times 471 \times 10^{-6} = 0.27$  Joule

It is worth noting that even though the ratio of volumes is 198, the ratio of energies is 0.2, since, for the present case,

$$K_v = \frac{\text{volume of (Stator - core + Rotor - core)}}{\text{Volume of air - gap}} = \frac{779+471}{6.3} = 198$$

$k_E = \text{Energy stored in cores} / \text{Energy stored in air-gap} = (0.45 + 0.27) / 3.6 = 0.2$

The ratio are like this due to  $\mu_r$  being 1000, and  $k_v / k_E = 198 / 0.2 = 1000$

Alternatively, an air-gap of volume 6.3 cm<sup>3</sup>, [surrounded by the magnetic medium of  $\mu_r = 1000$ ] is equivalent to the magnetic medium of volume  $6.3 \times 1000$  cm<sup>3</sup>.

$$\frac{\text{Converted equivalent volume of air-gap}}{\text{Volume of (Stator + Rotor)}} = \frac{6300}{779+471}$$

$$\frac{\text{Energy stored in air-gap}}{\text{Energy stored in (Stator + Rotor)}} = \frac{3.6}{(0.45+0.27)} = 5$$

This correlates the various parameters and confirms that the stored energy is maximum in the air-gap.

Or, one can now say that in the process of electro-mechanical energy-conversion, the air-gap plays a very vital role.

However, the stator-core and rotor-core help in completing the flux-path in a well defined manner for effective and efficient working of a rotary machine.

**Example 25.2.** An electromagnetic relay has an exciting coil of 800 turns. The coil has a cross-sectional area of 5 cm × 5 cm. Neglect reluctance of the magnetic circuit and fringing.

(a) (i) Find the coil inductance if the air-gap length is 0.5 cm.

(ii) Find the field energy stored for a coil current of 1.25 amp.

(b) Coil-current remaining constant at 1.25 A, find the mechanical energy output based on field-energy changes when the armature moves to a position for which  $x = 0.25$  cm. Assume slow movement of armature.

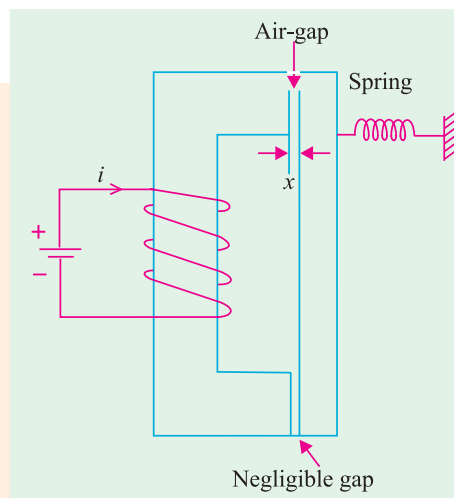

Fig. 25.5 Electro-magnetic relay

- (c) Repeat (b) above based on force-calculations and mechanical displacement.  
 (d) What will be change in above results of mechanical work done, if the mechanical movement is fast, keeping the flux initially constant ?

**Solution.**

$$(a) (i) \text{ Permeance at air-gap} = \frac{\mu_0 5 \times 5 \times 10^{-4}}{0.5 \times 10^{-2}} = 4\pi \times 10^{-7} \times 10^{-2} = 6.28 \times 10^{-7}$$

$$\text{Coil Inductance} = N_2^2 \mathcal{P}_m = 800 \times 800 \times 6.28 \times 10^{-7} = 0.402 \text{ H}$$

$$(ii) \text{ Energy stored in magnetic field} = 1/2 Li^2 = 1/2 \times 0.402 \times 1.25^2 = 0.314 \text{ joule}$$

$$(iii) W'_{fd} = 1/2 L(x)i^2 = 1/2 \left[ \frac{H^2 \mu_0 A}{l_x} \right] = \frac{1/2 \times 800 \times 800 \times 4\pi \times 10^{-7} \times 5 \times 5 \times 10^{-4}}{x} \times i^2$$

$$= \frac{1.005 \times 10^{-3}}{x} \times i^2$$

$$F_f = \frac{\delta [i^2 \times (1.005 \times 10^{-3})]}{\delta_x} = [1.005 \times 10^{-3}] \times i^2 \times \frac{-1}{x^2}$$

This is to be evaluated at  $x = 0.5 \times 10^{-2}$

$$= \frac{-1.005 \times 10^{-3} \times 1.25 \times 1.25}{(0.5 \times 10^{-2})^2} = -62.8 \text{ NW}$$

This force has to be balanced by the spring-tension.

(b) **Energy-computations :** Inductance for  $x = 0.25 \text{ cm}$  is first calculated.  $L(x_2) = N^2 \mathcal{P}_{m_2}$   
 $= 800 \times 800 \times 2 \times 6.28 \times 10^{-7} = 0.804 \text{ Henry}$

If the mechanical movement is slow, net mmf remains unchanged and the operating point moves along  $HC$  vertically upwards and settles at  $C$ . Added Electrical Energy input during change-over of the operating point from  $H$  to  $C$ ,

$$= \text{area of rectangle } BDCH = (\phi_2 - \phi_1) F_1$$

$$\left[ \frac{L(x_2) \cdot i - L(x_1) \cdot i}{N} \right] Ni$$

$$= i^2 [L(x_2) - L(x_1)] = 1.25^2 \times [0.804 - 0.402]$$

$$= 0.628 \text{ joule}$$

Out of this, the additional stored energy in field,  $dW_{fd} = 1/2 [L(x_2) - L(x_1)]$

$$= 0.314 \text{ joule}$$

The remaining 0.314 joule is transformed into mechanical form and is related to the work-done. This is obtained when the force on moving member is multiplied by the displacement.

$$\therefore \int_{x_1}^{x_2} dW_{mech} = 0.314 \text{ joule}$$

(c) As in a (iii) above,

$$F(x) = [1.005 \times 10^{-3} \times 1.25^2] [-1/x^2]$$

**Fig. 25.6** Graphical correlation of energy-terms for the relay

$$\begin{aligned}
 dW_{mech} &= F(x).dx \\
 W_{mech} &= \int_{x_1}^{x_2} F(x)dx = k. \left[ \int_{x_1}^{x_2} -1/x^2 dx \right] = -k. \int_{x_1}^{x_2} x^{-2} dx \\
 &= 1.005 \times 10^{-3} \times 1.25^2 \times \left[ \frac{1}{0.25} - \frac{1}{0.5} \right] \times 10^2 = \frac{1.005 \times 1.25^2}{10} \times 2 = 0.314 \text{ joule}
 \end{aligned}$$

This agrees with answer obtained in (b) above.

With fast movement of armature, the operating point will move from H to K first, then follow the path *KC*.

This means that the energy represented by the area of the triangle *KHC* corresponds to the reduced consumption of energy.

$$OC \text{ has a slope of } \mathcal{P}_{m_2} = 12.56 \times 10^{-7}$$

$$OH \text{ has a slope of } \mathcal{P}_{m_1} = 6.28 \times 10^{-7}$$

*BK* = mmf required for establishing a flux of  $\phi_1$  with an air-gap of 0.25 cm

$$BK = \frac{1}{2} OA = \frac{1}{2} \times (800 \times 1.25) = 500 \text{ amp-turns} = HK \text{ in the present case.}$$

$$\begin{aligned}
 \text{Area of the triangle } KHC &= \frac{1}{2} \times KH \times HC \\
 &= \frac{1}{2} \times 500 \times [\phi_2 - \phi_1] \\
 &= \frac{1}{4} \text{th of area of rectangle } BDCH, \text{ in this case} \\
 &= \frac{1}{4} \times 0.628 = 0.157 \text{ joule.}
 \end{aligned}$$

$$\begin{aligned}
 \text{Hence, Electrical energy fed during this process} &= \text{area } BKCD \\
 &= \text{area } BDCH - \text{area } KHC = 0.628 - 0.157 = 0.471 \text{ joule}
 \end{aligned}$$

$$\begin{aligned}
 \text{Increase in field energy stored } \Delta W'_{fld} &= \text{area } OKH \\
 &= \text{area } OHC - \text{area } KHC = 0.314 - 0.157 = 0.157
 \end{aligned}$$

$$\text{Mechanical Energy output} = 0.471 - 0.157 = 0.314 \text{ Joule}$$

It indicates that with fast movement, the electrical energy-input and the field-stored energy have decreased by 0.157 J each but the mechanical-energy-term remains unaffected by fast or slow movements of armature.

## 25.7. Dynamic Equations and System-model of a Simple System

It is quite necessary to analyze electro-mechanical conversion system for predicting the performance and/or for monitoring the system. A simple system is being taken up here to deal with dynamic equations and a simple model with its components is being related to the system. The details will vary from system to system, and accordingly the equations will vary.

Fig. 25.7 shows different components of such a system meant for electrical to mechanical conversion. On one side, an electrical source feeds the device at the 'electrical port'. On the other side, a force  $f_e$  is developed at the 'mechanical port'. Mechanical load is connected to this port.

**(a) At Electrical Port :** A voltage source is shown to feed the device.  $r$  is its effective internal resistance. At the electrical port, the inputs are  $\lambda$  (= flux linkage with the coil) and  $i$ . From  $\lambda$ , the voltage induced in the coil can always be evaluated.

**(b) Role of the Conversion device:** With these inputs, the device converts the energy into mechanical form, and is available as a force  $f_e$  (in case of linear motions), and, displacement  $x$  measured from a suitable reference.

(c) **At the Mechanical Port:** The possible items are: spring, damper, mass and an applied mechanical force. Their natural and simple dependence on displacement  $x$  and its derivatives are indicated below:

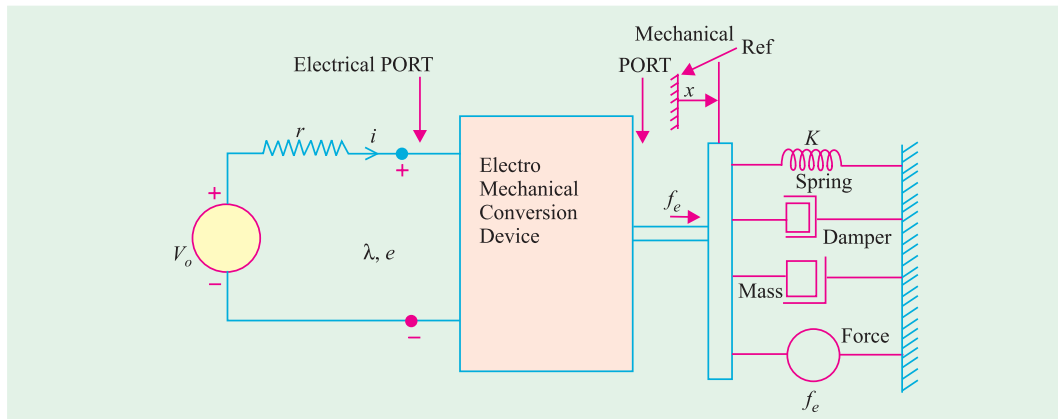

Fig. 25.7 Linear motion: MODEL

- (i) **Spring:** Force required to overcome spring elongation is proportional to the displacement  $x$ .
- (ii) **Damper:** Force required to overcome damping action in the system is proportional to derivative of  $x$ .
- (iii) **Mass:** Force required to overcome acceleration of mass is proportional to second derivative of  $x$ .
- (iv) **Applied force,  $f_o$ :** This has to be overcome by  $f_e$ . In terms of an equation, these terms are related as follows:

$$f_e = k_s (x - x_o) + B\dot{x} + M\ddot{x} + f_o$$

where

$k_s$  = spring constant

$x_o$  = value of  $x$  for unstretched spring

$B$  = damping constant

$M$  = Mass to be accelerated

$f_o$  = External mechanical force applied to the system.

### 25.8. Statically induced emf and Dynamically Induced emf :

In Fig. 25.7 source voltage is  $v_o$ . Let  $L(x)$  be the coil inductance as a function of displacement  $x$ . In a very general case,

$$\begin{aligned} v_o(t) &= ri + d\lambda/dt \\ &= ri + d/dt [L(x) \times i] \\ &= ri + L(x). di/dt + i. dL(x)/dx. dx/dt \end{aligned}$$

The second term on the right-hand side is statically induced emf (or transformer-emf), since change of current with time is responsible for it. This cannot produce any force (or torque) and hence cannot convert energy from electrical to mechanical form (or vice-versa).

The third term on the right hand side includes the speed ( $= dx/dt$ ) and dependence of  $L(x)$  on  $x$ . Any of these, if non-existent, will mean that third term reduces to zero. This term relates dynamically induced emf ( $=$  speed emf) and is the main indicator of the process of electro-

mechanical energy conversion. So, for conversion, there must be an inductance which varies with the system position, and a motion must be there. In addition, coil must carry a current.

Having understood the linear-motion-system, it is easier to understand the system with rotary motion, with due modifications.

**Example 25.3.** A doubly excited rotating machine has the following self and mutual inductances.

$$\begin{aligned} r_s &= 40 \Omega, & L_s &= 0.16 \text{ H} \\ r_r &= 2 \Omega, & L_r &= 0.04 + 0.02 \cos 2\theta \\ M_{sr} &= 0.08 \cos \theta \end{aligned}$$

where  $\theta$  is the space-angle between axes of rotor-coil and of stator-coil. The rotor is revolving at a speed of 100 radians/sec. For  $i_s = 10$  Amp d. c., and  $i_r = 2$  Amp d. c., obtain an expression for torque and corresponding electrical power.

[Rajiv Gandhi Technical University, Bhopal, Summer 2001]

**Solution.**  $W_{fld}$  = Total energy stored

$$\begin{aligned} &= \frac{1}{2} L_s i_s^2 + \frac{1}{2} L_r i_r^2 + M_{sr} i_s i_r \\ &= \frac{1}{2} (0.16) i_s^2 + \frac{1}{2} [0.04 + 0.02 \cos 2\theta] i_r^2 \\ &\quad + [0.08 \cos \theta] i_s i_r \end{aligned}$$

since  $i_s$  and  $i_r$  are direct currents of constant magnitudes, there is no variation with  $\phi$  or with t. Relating torque with  $W_{fld}$  and substituting current-magnitudes,

$$\begin{aligned} \text{Torque, } T &= \frac{-dW_{fld}}{d\theta} = -[0 + \frac{1}{2} \times 0.02 \times 2^2 (-2 \sin 2\theta) + 0.08 (-\sin \theta) (10 \times 2)] \\ &= 0.08 \sin 2\theta + 1.6 \sin \theta \\ &= 1.6 \sin \theta + 0.08 \sin 2\theta \text{ Nw-m} \end{aligned}$$

On the right hand side, the first term is electromagnetic Torque which is dependent on both the currents. Second term is dependent only on one current, and is of the type categorized as Reluctance-torque which depends on non-cylindrical shape, in this case, on the stator side, as shown in Fig. 25.8

Fig. 25.8

Starting from  $W_{fld}$ , electrical power can be expressed, since it is well-known that

Power = time rate of change of energy

$$\begin{aligned} \text{Electrical power, } p &= \frac{dW_{fld}}{dt} \\ &= \frac{d}{dt} \left[ \frac{1}{2} L_s i_s^2 + \frac{1}{2} L_r i_r^2 + M_{sr} i_s i_r \right] \\ &= \frac{1}{2} i_s^2 \frac{d}{dt} (L_s) + \frac{1}{2} i_r^2 \frac{d}{dt} (L_r) + i_s i_r \frac{d}{dt} (M_{sr}) \end{aligned}$$

$$\begin{aligned}
 &= \frac{1}{2} i_s^2 \left[ \frac{d}{d\theta} (L_s) \right] \frac{d\theta}{dt} + \frac{1}{2} i_r^2 \left[ \frac{d}{d\theta} (L_r) \right] \frac{d\theta}{dt} + i_s i_r \left[ \frac{d}{d\theta} (M_{sr}) \right] \frac{d\theta}{dt} \\
 &= \frac{1}{2} i_s^2 [\text{zero}] \times 100 + \frac{1}{2} i_r^2 [-0.02 \times 2 \times \sin 2\theta] \times 100 + i_s i_r [-0.08 \sin \theta] \times 100
 \end{aligned}$$

Substituting numerical values of currents, the electrical power is expressed as a function of  $\theta$ , as below :

$$\begin{aligned}
 p &= [\text{zero} + (-8) \sin 2\theta + (-160) \sin \theta] \text{ watts} \\
 &= [-160 \sin \theta - 8 \sin 2\theta] \text{ watts}
 \end{aligned}$$

Proper interpretation of sign of power (as dependent on  $\theta$ ) is important. Positive power is received by the coils, while negative power is received by the source.

**Example 25.4.** An inductor has an inductance which varies with displacement  $x$  as

$$L = 2 L_o / [1 + (x / x_o)]$$

Where  $L_o = 50 \text{ mh}$ ,  $x_o = 0.05 \text{ cm}$ ,  $x = \text{displacement in cm}$ ,

The coil resistance is  $0.5 \text{ ohm}$ .

- (a) The displacement  $x$  is held constant at  $0.075 \text{ cm}$ , and the current is increased from  $0$  to  $3 \text{ amp}$ . Find the resultant magnetic stored energy in the inductor.  
 (b) The current is then held constant at  $3 \text{ amp}$  and the displacement is increased to  $0.15 \text{ cm}$ . Find the corresponding change in the magnetic stored energy.

**Note.** Assume that all electrical transients are negligible.

**Solution.** (a) Inductance at  $x = 0.075 \text{ cm}$  is calculated first.

$$L_1 = \frac{2L_o}{1 + (0.075/0.05)} = 40 \text{ mH}$$

$\lambda_1 = L_1 \times \text{current} = 120 \times 10^{-3}$ , corresponding to point A in Fig. 25.9

$$W_{fld} = \frac{1}{2} L_1 (3)^2 = \frac{1}{2} (40 \times 10^{-3} \times 9) = 0.18 \text{ joule}$$

(b) Inductance for  $x = 0.15 \text{ cm}$  is to be calculated now.

$$L_2 = \frac{2L_o}{1 + (0.15/0.05)} = 25 \text{ mH}$$

With current held constant at  $3 \text{ amp}$ , the flux-Linkage is now  $\lambda_2 = (25 \times 10^{-3}) \times 3 = 75 \times 10^{-3}$

Since the current is constant at  $3 \text{ amp}$ , magnetic stored energy is reduced by the area of triangle  $OAB$ , in Fig. 25.9

Area of triangle  $OAB = \frac{1}{2} \times 3 \times (120 - 75) 10^{-3} = 0.0675 \text{ joule}$

**Check :** Stored-energy at B in terms of  $L_2$  and  $i$ , is given by

$$W_{fld} = \frac{1}{2} (25 \times 10^{-3}) \times 3^2 = 0.1125 \text{ joule}$$

$$\begin{aligned}
 \text{Alternatively, } W_{fld2} &= W_{fld1} - \text{area of } \Delta OAB \\
 &= 0.18 - 0.0675 = 0.1125 \text{ Joule}
 \end{aligned}$$

Fig. 25.9

**Example 25.5.** If the inductor in the previous case is connected to a voltage source which increases from 0 to 3 V [part (a)] and then is held constant at 3 V [part (b)], repeat the problem, assuming that electrical transients are negligible.

**Solution.** Coil resistance is 0.5 ohm. When the voltage reaches 3 V, the coil current is 6 amp. In part (a),  $L_1 = 40$  mH. Hence,  $W_{fld3} = \text{energy stored} = \frac{1}{2} L_1 i_1^2 = 0.72$  joule, at point C in Fig. 25.10. In part (b),  $L_2 = 25$  mH. The current is held constant at 6 amp. Working on similar lines,

$\Delta W_{fld} = \text{change in the field energy stored} = \text{area of triangle } ODC$  or  $\Delta W_{fld} = W_{fld3} - W_{fld4}$

$$W_{fld} = \frac{1}{2} \times 25 \times 10^{-3} \times 36 = 0.45 \text{ Joule, at point D}$$

$$\text{Change in energy stored in the field} = W_{fld3} - W_{fld4} = 0.72 - 0.45 = 0.27 \text{ joule}$$

Or  $\Delta W_{fld} = \text{area of } \triangle ODC = \frac{1}{2} \times 6 \times (\lambda_3 - \lambda_4)$

$$\text{Here } \lambda_3 = 40 \times 10^{-3} \times 6, \text{ and } \lambda_4 = 25 \times 10^{-3} \times 6$$

$$\Delta W_{fld} = \frac{1}{2} \times 6 \times 6 \times 10^{-3} (40 - 25) = 0.27 \text{ joule}$$

Fig. 25.10

**Example 25.6.** A coil of an electromagnetic relay is associated with a magnetic circuit whose reluctance is given by

$$= a + bx$$

where  $a$  and  $b$  are positive constants decided by the details of the magnetic circuit, in which  $x$  is the length of the air-gap between fixed and movable members. If the coil is connected to an A.C. source where voltage is described by

$$v = V_m \sin \omega t,$$

find the expression for the average force on armature, with air-gap held constant at  $x$ .

**Solution.** If  $\phi = \text{flux established, in Webers}$

$$N = \text{number of turns on the coil, } \lambda = \text{flux-linkage in Weber-turns}$$

$$W_{fld} = \frac{1}{2} \mathcal{R} \phi^2$$

$$\text{And force } F = \frac{\delta W_{fld}}{\delta x} = \frac{1}{2} \phi^2 \frac{\delta \mathcal{R}}{\delta x} = -\frac{1}{2} b \phi^2$$

The current in the coil is given by

$$v = R + L \frac{di}{dt}$$

for which, the steady-state solution for current with an a.c. voltage applied to the coil is given by

$$I = \frac{V}{\sqrt{R^2 + \omega^2 L^2}} \angle -\theta \text{ where } \theta = \tan^{-1} \left( \frac{\omega L}{R} \right)$$

$$\text{RMS voltage, } V = (V_m) / \mathcal{R} \sqrt{2}$$

Instantaneous current  $i$  is expressed as

$$i = \frac{\sqrt{2}V}{\sqrt{R^2 + \omega^2 L^2}} \sin(\omega t - \theta)$$

Further,  $L = N^2/\mathcal{R}$

$$\phi = Ni/\mathcal{R} = \frac{\sqrt{2}NV}{(R\mathcal{R})^2 + (N^2\omega)^2} \sin(\omega t - \theta)$$

$$\text{Force, } F_f = \frac{\mathcal{R} - bN^2V^2}{(R\mathcal{R})^2 + (N^2\omega)^2} \sin^2(\omega t - \theta)$$

The last term  $\sin^2(\omega t - \theta)$  has a time average (over a cycle) of  $1/2$ .

$$\text{Hence, average force, } F_f(\text{av}) = -\frac{1}{2} \frac{\mathcal{R}bN^2V^2}{(R\mathcal{R})^2 + (N^2\omega)^2}$$

Force is in such a direction that  $x$  will be reduced, or that the energy stored tends to increase.

**Example 25.7.** Two coupled coils have self- and mutual-inductances as expressed below:

$$L_{11} = 1 + (1/x),$$

$$L_{22} = 0.5 + (1/x),$$

$$L_{12} = L_{21} = 1/x$$

These expressions are valid over a certain range of linear displacement  $x$ , in cms. The first coil is excited by a constant current of 20 A and the second one, by a constant current of  $-10$  A. Find

(a) mechanical work done if  $x$  changes from 0.5 to 1.0 cm

(b) energy supplied by the two electrical sources in (a) above.

**Solution.** With data given, substituting the values of currents,

$$\begin{aligned} W_{fld} &= \frac{1}{2}L_{11}i_1^2 + L_{12}i_1i_2 + \frac{1}{2}L_{22}i_2^2 \\ &= 225 + (50/x) \end{aligned}$$

$$F_f = -\delta W_{fld} / \delta x = 50/x^2$$

$$\begin{aligned} \text{(a) } \Delta W_{\text{mech}} &= \int_{0.5}^{1.0} (50/x^2) dx \\ &= 50[x^{-1} / -1]_{0.5}^{1.0} = +50 \text{ joules} \end{aligned}$$

At  $x = 0.5$ ,  $W_{fld} = 325$  joules, and

at  $x = 1.0$ ,  $W_{fld} = 275$  joules

Thus, increase in  $x$  from 0.50 to 1.0 cm decreases the stored energy in the field from 325 to 275 joules. The field-system, thus, releases an energy of 50 joules.

(b) Calculations of Energy input from electrical sources –

$$\begin{aligned} \lambda_1 &= L_{11} i_1 + L_{12} i_2 \\ &= 20 [1 + (1/x)] - 10 (1/x) = 20 + (10/x) \end{aligned}$$

At  $x = 0.5$ ,  $\lambda_1 = 20 + 20 = 40$  Wb-turns

$x = 1.0$ ,  $\lambda_1 = 20 + 10 = 30$  Wb-turns

$$\begin{aligned} \Delta W_{elec1} &= i_1 [\text{change in } \lambda_1 \text{ due to displacement}] \\ &= 20 \times (-10) = -200 \text{ Joules} \end{aligned}$$

Similarly,  $\lambda_2 = L_{12} i_1 + L_{22} i_2 = -5 + (10/x)$

At  $x = 0.5$ ,  $\lambda_2 = -5 + 20 = +15$  Wb-turns

$x = 1.0$ ,  $\lambda_2 = -5 + 10 = +5$  Wb-turns

$$\Delta W_{elec2} = (-10)(-10) = +100 \text{ Joules.}$$

Seeing the signs and numerical values, it can be seen that Source 1 receives an energy of 200 Joules, which comes from three constituents:

100 J from source 2,

50 J from field energy stored,

and 50 J from mechanical system.

### Tutorial Problems 25.1

(a) A magnetic circuit has a coil with 1000 turns. Its reluctance is expressed as

$$\mathcal{R} = [8.5 + 40g] \times 10^{-3} \text{ MKS units}$$

where  $g$  = air-gap length in mm, between fixed and movable parts. For a coil current of 2.0 amp held constant and with slow movement, calculate the change in the field energy stored, if the length of the air-gap changes from 0.20 to 0.15 cm. Calculate the mechanical force experienced by the system.

**Hint:**  $\Delta W_e = i(\lambda_2 - \lambda_1)$ ,  $\Delta W_{fld} = \frac{1}{2} \Delta W_e$

Force,  $F = -\Delta W_{fld} / \Delta x$

[Ans.  $\Delta W_{fld} = 6.60$  J, Force = 13200 Nw]

(b) An electro-magnetic relay with an air-gap of  $x$  cm has the current and flux-linkage relationship as

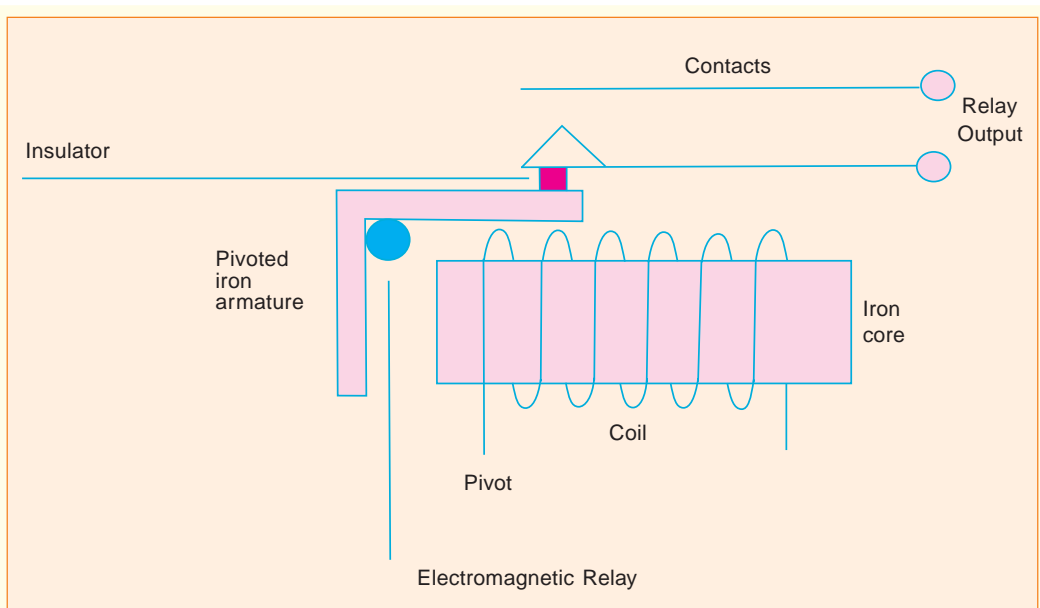

$$i = \lambda^2 + \lambda(0.5 - x)^2 \text{ amp, for } x < 0.5 \text{ cm}$$

Find the force on armature as a function of  $\lambda$  and  $x$ .

**Hint:**  $W_f(\lambda, x) = \int_{0.5}^{1.0} id \lambda$

And  $F_f = -\delta W_f / \delta x$

[Ans.  $W_f(\lambda, x) = (\lambda^3/3) + (\lambda^2/2)(0.5 - x)^2$   
 $F_f = \lambda^2(0.5 - x)$

(c) For a rotary system, the stator-coil and the rotor-coil have self and mutual-inductances as described below, with suffix 1 for stator and 2 for rotor:

$$L_{11} = L_{22} = 4 - (6\theta / \pi) \quad \text{for } 0 < \theta < \pi / 2$$

$$= 1 + (6 / \pi) (\theta - 0.5 \pi) \quad \text{for } \pi / 2 < \theta < \pi$$

(Note: Self inductances cannot be negative.)

$$L_{12} = L_{21} = 6 (1 - 2\theta / \pi) \quad \text{for } 0 < \theta < \pi$$

Evaluate the inductances and the torque for  $\theta = \pi / 4$  and the two coil currents of 5 amp constant in magnitude.

**Hint:**  $\delta L / \delta \theta$  contributes to torque.

$$[\text{Ans. } L_{11} = L_{22} = 2.5 \text{ H}$$

$$L_{12} = + 3 \text{ H}$$

$$T = 450 / \pi \text{ Nw}]$$

## D.C. GENERATORS

Generator converts mechanical energy into electrical energy using electromagnetic induction

### 26.1. Generator Principle

An electrical generator is a machine which converts mechanical energy (or power) into electrical energy (or power).

The energy conversion is based on the principle of the production of dynamically (or motionally) induced e.m.f. As seen from Fig. 26.1, whenever a conductor cuts magnetic flux, dynamically induced e.m.f. is produced in it according to Faraday's Laws of Electromagnetic Induction. This e.m.f. causes a current to flow if the conductor circuit is closed.

Hence, two basic essential parts of an electrical generator are (i) a magnetic field and (ii) a conductor or conductors which can so move as to cut the flux.

### 26.2. Simple Loop Generator

#### Construction

In Fig. 26.1 is shown a single-turn rectangular copper coil  $ABCD$  rotating about its own axis in a magnetic field provided by either permanent magnet or electromagnets. The two ends of the coil

Fig. 26.1

are joined to two slip-rings 'a' and 'b' which are insulated from each other and from the central shaft. Two collecting brushes (of carbon or copper) press against the slip-rings. Their function is to collect the current induced in the coil and to convey it to the external load resistance  $R$ .

The rotating coil may be called 'armature' and the magnets as 'field magnets'.

#### Working

Imagine the coil to be rotating in clock-wise direction (Fig. 26.2). As the coil assumes successive positions in the field, the flux linked with it changes. Hence, an e.m.f. is induced in it which is

proportional to the rate of change of flux linkages ( $e = Nd\Phi/dt$ ). When the plane of the coil is at right angles to lines of flux *i.e.* when it is in position, 1, then flux linked with the coil is maximum but **rate of change of flux linkages is minimum.**

It is so because in this position, the coil sides  $AB$  and  $CD$  do not cut or shear the flux, rather they slide along them *i.e.* they move parallel to them. Hence, there is no induced e.m.f. in the coil. Let us take this no-e.m.f. or vertical position of the coil as the starting position. The angle of rotation or time will be measured from this position.

Fig. 26.2

Fig. 26.3

As the coil continues rotating further, the rate of change of flux linkages (and hence induced e.m.f. in it) increases, till position 3 is reached where  $\theta = 90^\circ$ . Here, the coil plane is horizontal *i.e.* parallel to the lines of flux. As seen, the flux linked with the coil is minimum but **rate of change of flux linkages is maximum.** Hence, maximum e.m.f. is induced in the coil when in this position (Fig. 26.3).

In the next quarter revolution *i.e.* from  $90^\circ$  to  $180^\circ$ , the flux linked with the coil gradually **increases** but the rate of change of flux linkages **decreases**. Hence, the induced e.m.f. decreases gradually till in position 5 of the coil, it is reduced to zero value.

So, we find that in the first half revolution of the coil, no (or minimum) e.m.f. is induced in it when in position 1, maximum when in position 3 and no e.m.f. when in position 5. The direction of this induced e.m.f. can be found by applying Fleming's Right-hand rule which gives its direction from  $A$  to  $B$  and  $C$  to  $D$ . Hence, the direction of current flow is **ABMLCD** (Fig. 26.1). The current through the load resistance  $R$  flows from  $M$  to  $L$  during the first half revolution of the coil.

In the next half revolution *i.e.* from  $180^\circ$  to  $360^\circ$ , the variations in the magnitude of e.m.f. are similar to those in the first half revolution. Its value is maximum when coil is in position 7 and minimum when in position 1. But it will be found that the direction of the induced current is from  $D$  to  $C$  and  $B$  to  $A$  as shown in Fig. 26.1 (b). Hence, the path of current flow is along **DCLMBA** which is just the reverse of the previous direction of flow.

Therefore, we find that the current which we obtain from such a simple generator reverses its direction after every half revolution. Such a current undergoing periodic reversals is known as alternating current. It is, obviously, different from a direct current which continuously flows in one and the same direction. It should be noted that alternating current not only reverses its direction, it does not even keep its magnitude constant while flowing in any one direction. The two half-cycles may be called positive and negative half-cycles respectively (Fig. 26.3).

For making the flow of current unidirectional in the **external** circuit, the slip-rings are replaced by split-rings (Fig. 26.4). The split-rings are made out of a conducting cylinder which is cut into two halves or segments insulated from each other by a thin sheet of mica or some other insulating material (Fig. 26.5).

As before, the coil ends are joined to these segments on which rest the carbon or copper brushes.

It is seen [Fig. 26.6 (a)] that in the first half revolution current flows along **(ABMNLCD)** i.e. the brush No. 1 in contact with segment 'a' acts as the positive end of the supply and 'b' as the negative end. In the next half revolution [Fig. 26.6 (b)], the direction of the induced current in the coil has reversed. But at the same time, the positions of segments 'a' and 'b' have also reversed with the

Fig. 26.4

Fig. 26.5

result that brush No. 1 comes in touch with the segment which is positive i.e. segment 'b' in this case. Hence, current in the load resistance again flows from **M to L**. The waveform of the current through the external circuit is as shown in Fig. 26.7. **This current is unidirectional but not continuous like pure direct current.**

Fig. 26.6

Fig. 26.7

It should be noted that the position of brushes is so arranged that the change over of segments 'a' and 'b' from one brush to the other takes place when the plane of the rotating coil is at right angles to the plane of the lines of flux. It is so because in that position, the induced e.m.f. in the coil is zero.

Another important point worth remembering is that even now the current induced in the coil sides is alternating as before. It is only due to the rectifying action of the split-rings (also called commutator) that it becomes unidirectional in the external circuit. Hence, it should be clearly understood that even in the armature of a d.c. generator, the induced voltage is alternating.

### 26.3. Practical Generator

The simple loop generator has been considered in detail merely to bring out the basic principle

underlying construction and working of an actual generator illustrated in Fig. 26.8 which consists of the following essential parts :

- |                                    |                              |
|------------------------------------|------------------------------|
| 1. Magnetic Frame or Yoke          | 2. Pole-Cores and Pole-Shoes |
| 3. Pole Coils or Field Coils       | 4. Armature Core             |
| 5. Armature Windings or Conductors | 6. Commutator                |
| 7. Brushes and Bearings            |                              |

Of these, the yoke, the pole cores, the armature core and air gaps between the poles and the armature core or the magnetic circuit whereas the rest form the electrical circuit.

Fig. 26.8

#### 26.4. Yoke

The outer frame or yoke serves double purpose :

(i) It provides mechanical support for the poles and acts as a protecting cover for the whole machine and

(ii) It carries the magnetic flux produced by the poles.

In small generators where cheapness rather than weight is the main consideration, yokes are made of cast iron. But for large machines usually cast steel or rolled steel is employed. The modern process of forming the yoke consists of rolling a steel slab round a cylindrical mandrel and then welding it at the bottom. The feet and the terminal box etc. are welded to the frame afterwards. Such yokes possess sufficient mechanical strength and have high permeability.

#### 26.5. Pole Cores and Pole Shoes

The field magnets consist of pole cores and pole shoes. The pole shoes serve two purposes

(i) they spread out the flux in the air gap and also, being of larger cross-section, reduce the reluctance of the magnetic path (ii) they support the exciting coils (or field coils) as shown in Fig. 26.14.

There are two main types of pole construction.

(a) The pole core itself may be a solid piece made out of either cast iron or cast steel but the pole shoe is laminated and is fastened to the pole face by means of counter sunk screws as shown in Fig. 24.10.

(b) In modern design, the complete pole cores and pole shoes are built of thin laminations of annealed steel which are rivetted together under hydraulic pressure (Fig. 26.11). The thickness of laminations varies from 1 mm to 0.25 mm. The laminated poles may be secured to the yoke in any of the following two ways :

- (i) Either the pole is secured to the yoke by means of screws bolted through the yoke and into the pole body or
- (ii) The holding screws are bolted into a steel bar which passes through the pole across the plane of laminations (Fig. 26.12).

Fig. 26.9

Fig. 26.10

Fig. 26.11

Fig. 26.12

### 26.6. Pole Coils

The field coils or pole coils, which consist of copper wire or strip, are former-wound for the correct dimension (Fig. 26.13). Then, the former is removed and wound coil is put into place over the core as shown in Fig. 26.14.

When current is passed through these coils, they electromagnetise the poles which produce the necessary flux that is cut by revolving armature conductors.

### 26.7. Armature Core

It houses the armature conductors or coils and causes them to rotate and hence cut the magnetic flux of the field magnets. In addition to this, its most important function is to provide a path of very low reluctance to the flux through the armature from a  $N$ -pole to a  $S$ -pole.

It is cylindrical or drum-shaped and is built up of usually circular sheet steel discs or laminations approximately 0.5 mm thick (Fig. 26.15). It is keyed to the shaft.

The slots are either die-cut or punched on the outer periphery of the disc and the keyway is located on the inner diameter as shown. In small machines, the armature stampings are keyed directly to the shaft. Usually, these laminations are perforated for air ducts which permits axial flow of air through the armature for cooling purposes. Such ventilating channels are clearly visible in the laminations shown in Fig. 26.16 and Fig. 26.17.

Fig. 26.13

Fig. 26.14

Up to armature diameters of about one metre, the circular stampings are cut out in one piece as shown in Fig. 26.16. But above this size, these circles, especially of such thin sections, are difficult to handle because they tend to distort and become wavy when assembled together. Hence, the circular laminations, instead of being cut out in one piece, are cut in a number of suitable sections or segments which form part of a complete ring (Fig. 26.17).

Fig. 26.15

Fig. 26.16

A complete circular lamination is made up of four or six or even eight segmental laminations. Usually, two keyways are notched in each segment and are dove-tailed or wedge-shaped to make the laminations self-locking in position.

The purpose of using laminations is to reduce the loss due to eddy currents. Thinner the laminations, greater is the resistance offered to the induced e.m.f., smaller the current and hence lesser the  $I^2 R$  loss in the core.

### 26.8. Armature Windings

The armature windings are usually former-wound. These are first wound in the form of flat rectangular coils and are then pulled into their proper shape in a coil puller. Various conductors of the coils are insulated from each other. The conductors are placed in the armature slots which are lined with tough insulating material. This slot insulation is folded over above the armature conductors placed in the slot and is secured in place by special hard wooden or fibre wedges.

### 26.9. Commutator

The function of the commutator is to facilitate collection of current from the armature conductors. As shown in Art. 26.2, it rectified *i.e.* converts the alternating current induced in the armature conductors into unidirectional current in the external load circuit. It is of cylindrical structure and is built up of wedge-shaped segments of high-conductivity hard-drawn or drop forged copper. These

**Fig. 26.17**

**Fig. 26.18**

**Fig. 26.19**

segments are insulated from each other by thin layers of mica. The number of segments is equal to the number of armature coils. Each commutator segment is connected to the armature conductor by means of a copper lug or strip (or riser). To prevent them from flying out under the action of centrifugal forces, the segments have V-grooves, these grooves being insulated by conical micanite rings. A sectional view of commutator is shown in Fig. 26.18 whose general appearance when completed is shown in Fig. 26.19.

### 26.10. Brushes and Bearings

The brushes whose function is to collect current from commutator, are usually made of carbon or

graphite and are in the shape of a rectangular block. These brushes are housed in brush-holders usually of the box-type variety. As shown in Fig. 26.20, the brush-holder is mounted on a spindle and the brushes can slide in the rectangular box open at both ends. The brushes are made to bear down on the commutator by a spring whose tension can be adjusted by changing the position of lever in the notches. A flexible copper pigtail mounted at the top of the brush conveys current from the brushes to the holder. The number of brushes per spindle depends on the magnitude of the current to be collected from the commutator.

Because of their reliability, ball-bearings are frequently employed, though for heavy duties, roller bearings are preferable. The ball and rollers are generally packed in hard oil for quieter operation and for reduced bearing wear, sleeve bearings are used which are lubricated by ring oilers fed from oil reservoir in the bearing bracket.

### 26.11. Armature Windings

Now, we will discuss the winding of an actual armature. But before doing this, the meaning of the following terms used in connection with armature winding should be clearly kept in mind.

### 26.12. Pole-pitch

It may be variously defined as :

- (i) The periphery of the armature divided by the number of poles of the generator *i.e.* the distance between two adjacent poles.
- (ii) It is equal to the number of armature conductors (or armature slots) per pole. If there are 48 conductors and 4 poles, the pole pitch is  $48/4 = 12$ .

### 26.13. Conductor

The length of a wire lying in the magnetic field and in which an e.m.f. is induced, is called a conductor (or inductor) as, for example, length *AB* or *CD* in Fig. 26.21.

### 26.14. Coil and Winding Element

With reference to Fig. 26.21, the two conductors  $AB$  and  $CD$  along with their end connections constitute one coil of the armature winding. The coil may be single-turn coil (Fig. 26.21) or multi-turn coil (Fig. 26.22). A single-turn coil will have two conductors. But a multi-turn coil may have many conductors per coil side. In Fig. 26.22, for example, each coil side has 3 conductors. The

Fig. 26.21

Fig. 26.22

Fig. 26.23

group of wires or conductors constituting a coil side of a multi-turn coil is wrapped with a tape as a unit (Fig. 26.23) and is placed in the armature slot. It may be noted that since the beginning and the end of each coil must be connected to a commutator bar, there are as many commutator bars as coils for both the lap and wave windings (see Example 26.1).

The side of a coil (1-turn or multiturn) is called a winding element. Obviously, the number of winding elements is twice the number of coils.

### 26.15. Coil-span or Coil-pitch ( $Y_s$ )

It is the distance, measured in terms of armature slots (or armature conductors) between two sides of a coil. It is, in fact, the periphery of the armature spanned by the two sides of the coil.

If the pole span or coil pitch is equal to the pole pitch (as in the case of coil  $A$  in Fig. 26.24 where pole-pitch of 4 has been assumed), then winding is called **full-pitched**. It means that coil span is 180 electrical degrees. In this case, the coil sides lie under opposite poles, hence the induced e.m.f.s. in them are additive. Therefore, maximum e.m.f. is induced in the coil as a whole, it being the sum of the e.m.f.s induced in the two coil sides. For example, if there are 36 slots and 4 poles, then coil span is  $36/4 = 9$  slots. If number of slots is 35, then  $Y_s = 35/4 = 8$  because it is customary to drop fractions.

If the coil span is less than the pole pitch (as in coil  $B$  where coil pitch is  $3/4$ th of the pole pitch), then the

Fig. 26.24

winding is fractional-pitched. In this case, there is a phase difference between the e.m.fs. in the two sides of the coil. Hence, the total e.m.f. round the coil which is the vector sum of e.m.fs. in the two coil sides, is less in this case as compared to that in the first case.

**26.16. Pitch of a Winding ( $Y$ )**

In general, it may be defined as the distance round the armature between two successive conductors which are directly connected together. Or, it is the distance between the beginnings of two consecutive turns.

$$Y = Y_B - Y_F \text{ .....for lap winding}$$

$$= Y_B + Y_F \text{ .....for wave winding}$$

In practice, coil-pitches as low as eight-tenths of a pole pitch are employed without much serious reduction in the e.m.f. Fractional-pitched windings are purposely used to effect substantial saving in the copper of the end connections and for improving commutation.

**26.17. Back Pitch ( $Y_B$ )**

The distance, measured in terms of the armature conductors, which a coil advances on the back of the armature is called back pitch and is denoted by  $Y_B$ .

As seen from Fig. 26.28, element 1 is connected on the back of the armature to element 8. Hence,  $Y_B = (8 - 1) = 7$ .

**26.18. Front Pitch ( $Y_F$ )**

The number of armature conductors or elements spanned by a coil on the front (or commutator end of an armature) is called the front pitch and is designated by  $Y_F$ . Again in Fig. 26.28, element 8 is connected to element 3 on the front of the armature, the connections being made at the commutator segment. Hence,  $Y_F = 8 - 3 = 5$ .

Alternatively, the front pitch may be defined as the distance (in terms of armature conductors) between the second conductor of one coil and the first conductor of the next coil which are connected together at the front *i.e.* commutator end of the armature. Both front and back pitches for lap and wave-winding are shown in Fig. 26.25 and 26.26.

Fig. 26.25

Fig. 26.26

Fig. 26.27

**26.19. Resultant Pitch ( $Y_R$ )**

It is the distance between the beginning of one coil and the beginning of the next coil to which it is connected (Fig. 26.25 and 26.26).

As a matter of precaution, it should be kept in mind that all these pitches, though normally

stated in terms of armature conductors, are also sometimes given in terms of armature slots or commutator bars because commutator is, after all, an image of the winding.

### 26.20. Commutator Pitch ( $Y_C$ )

It is the distance (measured in commutator bars or segments) between the segments to which the two ends of a coil are connected. From Fig. 26.25 and 26.26 it is clear that for lap winding,  $Y_C$  is the **difference** of  $Y_B$  and  $Y_F$  whereas for wavewinding it is the **sum** of  $Y_B$  and  $Y_F$ . Obviously, commutator pitch is equal to the number of bars between coil leads. In general,  $Y_C$  equals the 'plex' of the lap-wound armature. Hence, it is equal to 1, 2, 3, 4 etc. for simplex-, duplex, triplex- and quadruplex etc. lap-windings.

Fig. 26.28

### 26.21. Single-layer Winding

It is that winding in which one conductor or one coil side is placed in each armature slot as shown in Fig. 26.27. Such a winding is not much used.

### 26.22. Two-layer Winding

In this type of winding, there are two conductors or coil sides per slot arranged in two layers. Usually, one side of every coil lies in the upper half of one slot and other side lies in the lower half of some other slot at a distance of approximately one pitch away (Fig. 26.28). The transfer of the coil from one slot to another is usually made in a radial plane by means of a peculiar bend or twist at the back end as shown in Fig. 26.29. Such windings in which two coil sides occupy each slot are most commonly used for all medium-sized machines. Sometimes 4 or 6 or 8 coil sides are used in each slot in several layers because it is not practicable to have too many slots (Fig. 26.30). The coil sides lying at the upper half of the slots are numbered odd *i.e.* 1, 3, 5, 7 etc. while those at the lower half are numbered even *i.e.* 2, 4, 6, 8 etc.

Fig. 26.29

Fig. 26.30

### 26.23. Degree of Re-entrant of an Armature Winding

A winding is said to be single re-entrant if on tracing through it once, all armature conductors are included on returning to the starting point. It is double re-entrant if only half the conductors are included in tracing through the winding once and so on.

### 26.24. Multiplex Winding

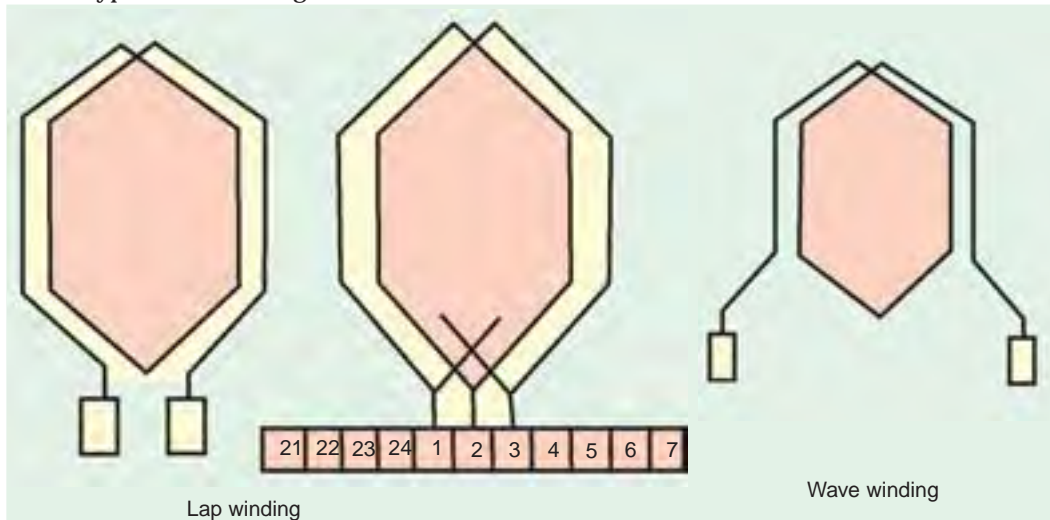

In such windings, there are several sets of completely closed and independent windings. If there is only one set of closed winding, it is called simplex wave winding. If there are two such windings on the same armature, it is called duplex winding and so on. The multiplicity affects a number of parallel paths in the armature. For a given number of armature slots and coils, as the multiplicity increases, the number of parallel paths in the armature increases thereby increasing the current rating but decreasing the voltage rating.

Multiplex Winding

### 26.25. Lap and Wave Windings

Two types of windings mostly employed for drum-type armatures are known as Lap Winding and Wave Winding. The difference between the two is merely due to the different arrangement of the end connections at the front or commutator end of armature. Each winding can be arranged progressively or retrogressively and connected in simplex, duplex and triplex. The following rules, however, apply to both types of the windings :

Lap winding

Wave winding

- (i) The front pitch and back pitch are each approximately equal to the pole-pitch *i.e.* windings should be full-pitched. This results in increased e.m.f. round the coils. For special purposes, fractional-pitched windings are deliberately used (Art. 26.15).
- (ii) Both pitches should be odd, otherwise it would be difficult to place the coils (which are former-wound) properly on the armature. For example, if  $Y_B$  and  $Y_F$  were both even, the *all* the coil sides and conductors would lie either in the upper half of the slots or in the lower

half. Hence, it would become impossible for one side of the coil to lie in the upper half. Hence, it would become impossible for one side of the coil to lie in the upper half of one slot and the other side of the same coil to lie in the lower half of some other slot.

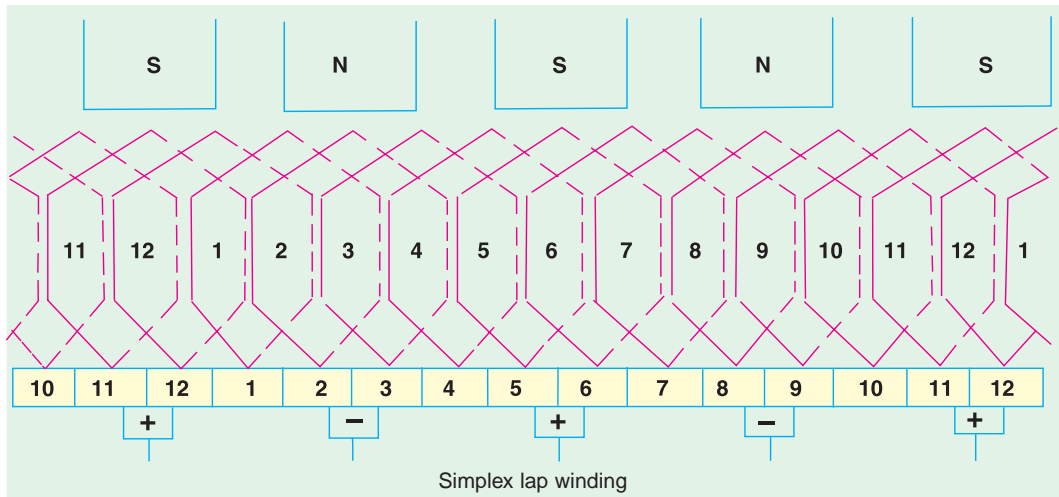

- (iii) The number of commutator segments is equal to the number of slots or coils (or half the number of conductors) because the front ends of conductors are joined to the segments in pairs.
- (iv) The winding must close upon itself *i.e.* if we start from a given point and move from one coil to another, then all conductors should be traversed and we should reach the same point again without a break or discontinuity in between.

### 26.26. Simplex Lap-winding\*

It is shown in Fig. 26.25 which employs single-turn coils. In lap winding, the finishing end of one coil is connected to a commutator segment and to the starting end of the adjacent coil situated under the same pole and so on, till all the coils have been connected. This type of winding derives its name from the fact it doubles or laps back with its succeeding coils.

Following points regarding simplex lap winding should be carefully noted :

1. The back and front pitches are odd and of opposite sign. But they cannot be equal. They differ by 2 or some multiple thereof.
2. Both  $Y_B$  and  $Y_F$  should be nearly equal to a pole pitch.
3. The average pitch  $Y_A = \frac{Y_B + Y_F}{2}$ . It equals pole pitch =  $\frac{Z}{P}$ .
4. Commutator pitch  $Y_C = \pm 1$ . (In general,  $Y_C = \pm m$ )
5. Resultant pitch  $Y_R$  is even, being the arithmetical difference of two odd numbers, *i.e.*,  $Y_R = Y_B - Y_F$
6. The number of slots for a 2-layer winding is equal to the number of coils (*i.e.* half the number of coil sides). The number of commutator segments is also the same.

\* However, where heavy currents are necessary, duplex or triplex lap windings are used. The duplex lap winding is obtained by placing two similar windings on the same armature and connecting the even-numbered commutator bars to one winding and the odd-numbered ones to the second winding. Similarly, in triplex lap winding, there would be three windings, each connected to one third of the commutator bars.

7. The number of parallel paths in the armature =  $mP$  where  $m$  is the multiplicity of the winding and  $P$  the number of poles.

Taking the first condition, we have  $Y_B = Y_F \pm 2$ .\*\*

(a) If  $Y_B > Y_F$  i.e.  $Y_B = Y_F + 2$ , then we get a progressive or right-handed winding i.e. a winding which progresses in the clockwise direction as seen from the commutator end. In this case, obviously,  $Y_C = +1$ .

(b) If  $Y_B < Y_F$  i.e.  $Y_B = Y_F - 2$ , then we get a retrogressive or left-handed winding i.e. one which advances in the anti-clockwise direction when seen from the commutator side. In this case,  $Y_C = -1$ .

(c) Hence, it is obvious that

$$\left. \begin{aligned} Y_F &= \frac{Z}{P} - 1 \\ Y_B &= \frac{Z}{P} + 1 \end{aligned} \right\} \text{for progressive winding and} \quad \left. \begin{aligned} Y_F &= \frac{Z}{P} + 1 \\ Y_B &= \frac{Z}{P} - 1 \end{aligned} \right\} \text{for retrogressive winding}$$

Obviously,  $Z/P$  must be even to make the winding possible.

### 26.27. Numbering of Coils and Commutator Segments

In the d.c. winding diagrams to follow, we will number the coils only (not individual turns). The upper side of the coil will be shown by a firm continuous line whereas the lower side will be shown by a broken line. The numbering of coil sides will be consecutive i.e. 1, 2, 3 ..... etc. and such that odd numbers are assigned to the top conductors and even numbers to the lower sides for a two-layer winding. The commutator segments will also be numbered consecutively, the number of the segments will be the same as that of the upper side connected to it.

**Example 26.1.** Draw a developed diagram of a simple 2-layer lap-winding for a 4-pole generator with 16 coils. Hence, point out the characteristics of a lap-winding.

(Elect. Engineering, Madras Univ. 1981)

**Solution.** The number of commutator segments = 16

Number of conductors or coil sides  $16 \times 2 = 32$  ; pole pitch =  $32/4 = 8$

Now remembering that (i)  $Y_B$  and  $Y_F$  have to be odd and (ii) have to differ by 2, we get for a progressive winding  $Y_B = 9$  ;  $Y_F = -7$  (retrogressive winding will result if  $Y_B = 7$  and  $Y_F = -9$ ). Obviously, commutator pitch  $Y_C = -1$ .

[Otherwise, as shown in Art. 26.26, for progressive winding

$$Y_F = \frac{Z}{P} - 1 = \frac{32}{4} - 1 = 7 \text{ and } Y_B = \frac{Z}{P} - 1 = \frac{32}{4} + 1 = 9]$$

The simple winding table is given as under :

<b>Back Connections</b>		<b>Front Connections</b>
1 to (1 + 9) = 10	—————>	10 to (10 - 7) = 3
3 to (3 + 9) = 12	—————>	12 to (12 - 7) = 5
5 to (5 + 9) = 14	—————>	14 to (14 - 7) = 7
7 to (7 + 9) = 16	—————>	16 to (16 - 7) = 9
9 to (9 + 9) = 18	—————>	18 to (18 - 7) = 11
11 to (11 + 9) = 20	—————>	20 to (20 - 7) = 13
13 to (13 + 9) = 22	—————>	22 to (22 - 7) = 15
15 to (15 + 9) = 24	—————>	24 to (24 - 7) = 17
17 to (17 + 9) = 26	—————>	26 to (26 - 7) = 19
19 to (19 + 9) = 28	—————>	28 to (28 - 7) = 21

\*\* In general,  $Y_B = Y_F \pm 2m$  where  $m = 1$  for simplex lap winding and  $m = 2$  for duplex lap winding etc.

21 to $(21 + 9) = 30$	—————>	30 to $(20 - 7) = 23$
23 to $(23 + 9) = 32$	—————>	32 to $(32 - 7) = 25$
25 to $(25 + 9) = 34 = (34 - 32) = 2$	—————>	2 to $(34 - 7) = 27$
27 to $(27 + 9) = 36 = (36 - 32) = 4$	—————>	4 to $(36 - 7) = 29$
29 to $(29 + 9) = 38 = (38 - 32) = 6$	—————>	6 to $(38 - 7) = 31$
31 to $(31 + 9) = 40 = (40 - 32) = 8$	—————>	8 to $(40 - 7) = 33 = (33 - 32) = 1$

The winding ends here because we come back to the conductor from where we started.

We will now discuss the developed diagram which is one that is obtained by imagining the armature surface to be removed and then laid out flat so that the slots and conductors can be viewed without the necessity of turning round the armature in order to trace out the armature windings. Such a developed diagram is shown in Fig. 26.31.

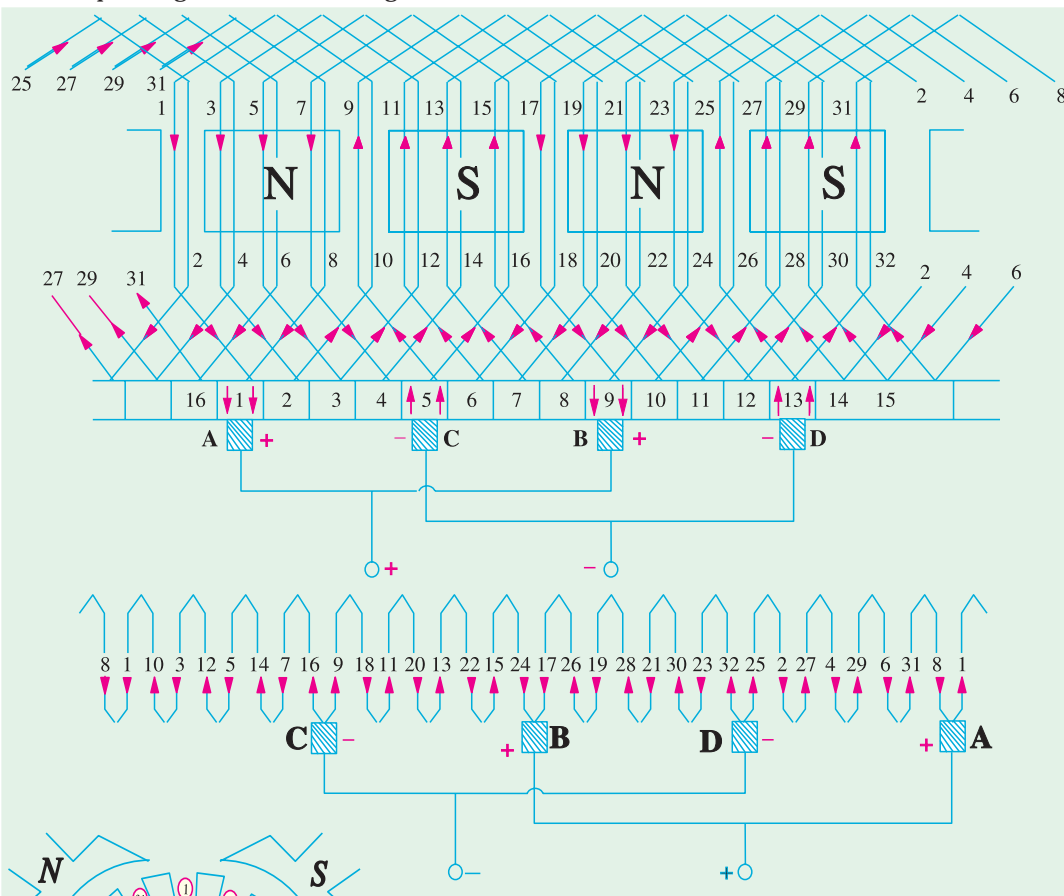

Fig. 26.31

Fig. 26.32

The procedure of developing the winding is this :

Front end of the upper side of coil No. 1 is connected to a commutator segment (whose number is also 1). The back end is joined at the back to the  $1 + 9 = 10$ th coil side in the lower half of 5th slot. The front end of coil side 10 is joined to commutator segment 2 to which is connected the front end of  $10 - 7 = 3$  i.e. 3rd coil side lying in the upper half of second armature slot. In this way, by travelling 9 coil sides to the right at the back and 7 to the left at the

front we complete the winding, thus including every coil side once till we reach the coil side 1 from where we started. Incidentally, it should be noted that all upper coil sides have been given odd numbers, whereas lower ones have been given even numbers as shown in the polar diagram (Fig. 26.32) of the winding of Fig. 26.31.

Brush positions can be located by finding the direction of currents flowing in the various conductors. If currents in the conductors under the influence of a  $N$ -pole are assumed to flow downwards (as shown), then these will flow upwards in conductors under the influence of  $S$ -pole. By putting proper arrows on the conductors (shown separately in the equivalent ring diagram), it is found that commutator bars No. 1 and 9 are the meeting points of e.m.fs. and hence currents are flowing out of these conductors. The positive brushes should, therefore, be placed at these commutator bars. Similarly, commutator bars No. 5 and 13 are the separating points of e.m.fs. hence negative brushes are placed there. In all, there are four brushes, two positive and two negative. If brushes of the same polarity are connected together, then all the armature conductors are divided into four parallel paths.

Fig. 26.33

Division of conductors into parallel paths is shown separately in the schematic diagram of Fig. 26.34. Obviously, if  $I_a$  is the total current supplied by the generator, then current carried by each parallel path is  $I_a/4$ .

Summarizing these conclusions, we have

1. The total number of brushes is equal to the number of poles.
2. There are as many parallel paths in the armature as the number of poles. That is why such a winding is sometimes known as 'multiple circuit' or 'parallel' winding. In general, number of parallel paths in armature =  $mP$  where  $m$  is the multiplicity (plex) of the lap winding. For example, a 6-pole duplex lap winding has  $(6 \times 2) = 12$  parallel paths in its armature.
3. The e.m.f. between the +ve and -ve brushes is equal to the e.m.f. generated in any one of the parallel paths. If  $Z$  is the total number of armature conductors and  $P$  the number of poles, then the number of armature conductors (connected in series) in any parallel path is  $Z/P$ .

$\therefore$  Generated e.m.f.  $E_g = (\text{Average e.m.f./conductor}) \times \frac{Z}{P} = e_{av} \times \frac{Z}{P}$

4. The total or equivalent armature resistance can be found as follows :

Let  $l$  = length of each armature conductor;  $S$  = its cross-section

$A$  = No. of parallel paths in armature =  $P$  – for simplex lap winding

$R$  = resistance of the whole winding then  $R = \frac{\rho l}{S} \times Z$

Fig. 26.34

$$\text{Resistance of each path} = \frac{\rho l Z}{S \times A}$$

There are  $P$  (or  $A$ ) such paths in parallel, hence equivalent resistance

$$= \frac{1}{A} \times \frac{\rho l Z}{SA} = \frac{\rho l Z}{SA^2}$$

5. If  $I_a$  is the total armature current, then current per parallel path (or carried by each conductor) is  $I_a/P$ .

### 26.28. Simplex Wave Winding\*

From Fig. 26.31, it is clear that in lap winding, a conductor (or coil side) under one pole is connected at the back to a conductor which occupies an almost corresponding position under the *next* pole of *opposite* polarity (as conductors 3 and 12). Conductor No. 12 is then connected to conductor No. 5 under the *original* pole but which is a little removed from the initial conductor No. 3. If, instead of returning to the same *N*-pole, the conductor No. 12 were taken *forward* to the next *N*-pole, it would make no difference so far as the direction and magnitude of the e.m.f. induced in the circuit are concerned.

\* Like lap winding, a wave winding may be duplex, triplex or may have any degree of multiplicity. A simplex wave winding has two paths, a duplex wave winding four paths and a triplex one six paths etc.

Fig. 26.35

As shown in Fig. 26.35, conductor  $AB$  is connected to  $CD$  lying under  $S$ -pole and then to  $EF$  under the next  $N$ -pole. In this way, the winding progresses, passing successively under every  $N$ -pole and  $S$ -pole till it returns to a conductor  $A'B'$  lying under the original pole. Because the winding progresses in one direction round the armature in a series of 'waves', it is known as wave winding.

If, after passing once round the armature, the winding falls in a slot to the left of its starting point (as  $A'B'$  in Fig. 26.35) then the winding is said to be retrogressive. If, however, it falls one slot to the right, then it is progressive.

Assuming a 2-layer winding and supposing that conductor  $AB$  lies in the upper half of the slot, then going once round the armature, the winding ends at  $A'B'$  which must be at the upper half of the slot at the left or right. Counting in terms of **conductors**, it means that  $AB$  and  $A'B'$  differ by two conductors (although they differ by one slot).

From the above, we can deduce the following relations. If  $P = \text{No. of poles}$ , then

$$\left. \begin{array}{l} Y_B = \text{back pitch} \\ Y_F = \text{front pitch} \end{array} \right\} \text{ nearly equal to pole pitch}$$

then 
$$Y_A = \frac{Y_B + Y_F}{2} = \text{average pitch}; Z = \text{total No. of conductors or coil sides}$$

$$\text{Then, } Y_A \times P = Z \pm 2 \quad Y_A = \frac{Z \pm 2}{P}$$

Since  $P$  is always even and  $Z = PY_A \pm 2$ , hence  $Z$  must always be even. Put in another way, it means that  $\frac{Z \pm 2}{P}$  must be an even integer.

The plus sign will give a progressive winding and the negative sign a retrogressive winding.

#### Points to Note :

1. Both pitches  $Y_B$  and  $Y_F$  are odd and of the same sign.
2. Back and front pitches are nearly equal to the pole pitch and may be equal or differ by 2, in which case, they are respectively one more or one less than the average pitch.
3. Resultant pitch  $Y_R = Y_F + Y_B$
4. Commutator pitch,  $Y_C = Y_A$  (in lap winding  $Y_C = \pm 1$ ).

$$\text{Also, } Y_C = \frac{\text{No. of Commutator bars} \pm 1}{\text{No. of pair of poles}}$$

5. The average pitch which must be an integer is given by

$$Y_A = \frac{Z \pm 2}{P} = \frac{\frac{Z}{2} + 1}{P/2} = \frac{\text{No. of Commutator bars} \pm 1}{\text{No. of pair of poles}}$$

It is clear that for  $Y_A$  to be an integer, there is a restriction on the value of  $Z$ . With  $Z = 32$ , this winding is impossible for a 4-pole machine (though lap winding is possible). Values of  $Z = 30$  or  $34$  would be perfectly alright.

6. The number of coils i.e.  $N_C$  can be found from the relation.

$$N_C = \frac{PY_A \pm 2}{2}$$

This relation has been found by rearranging the relation given in (5) above.

7. It is obvious from (5) that for a wave winding, the number of armature conductors with 2 either added or subtracted must be a multiple of the number of poles of the generator. This restriction eliminates many even numbers which are unsuitable for this winding.
8. The number of armature parallel paths =  $2m$  where  $m$  is the multiplicity of the winding.

**Example 26.2.** Draw a developed diagram of a simplex 2-layer wave-winding for a 4-pole d.c. generator with 30 armature conductors. Hence, point out the characteristics of a simple wave winding. (Elect. Engg-I, Nagpur Univ. 1991)

**Solution.** Here,  $Y_A = \frac{30 \pm 2}{4} = 8^*$  or 7. Taking  $Y_A = 7$ , we have  $Y_B = Y_F = 7$

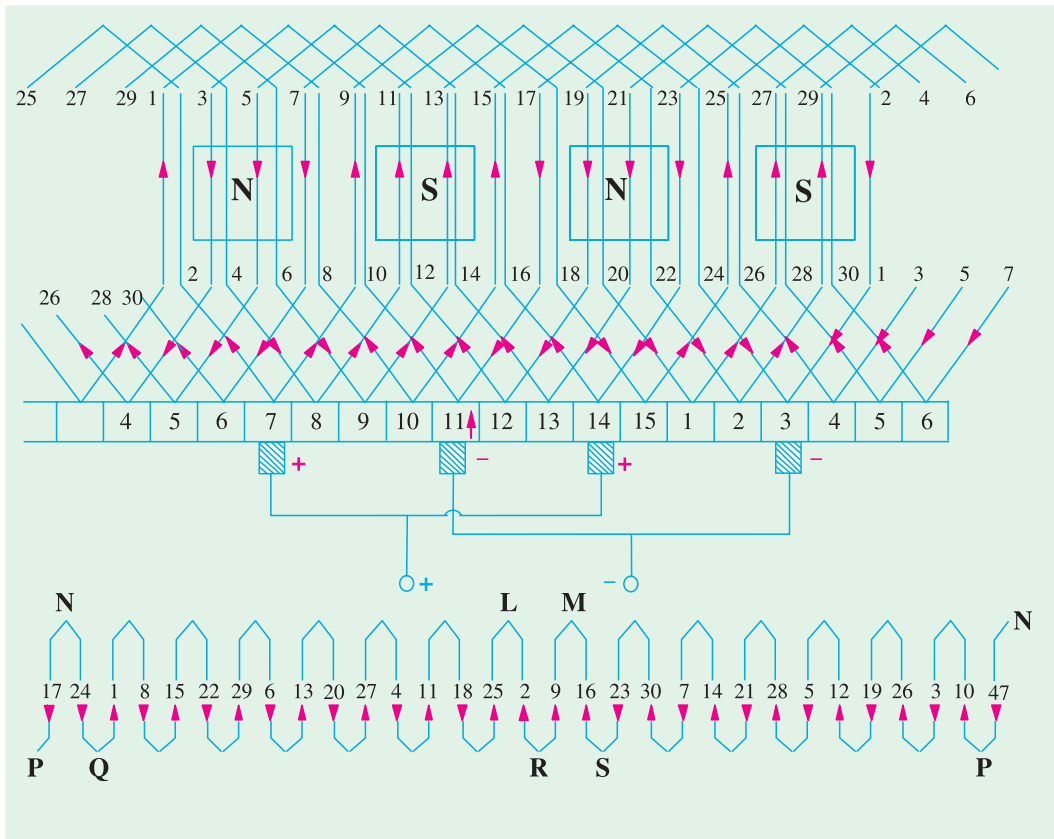

Fig. 26.36

As shown in Fig. 26.36 and 26.37, conductor No. 5 is taken to conductor No.  $5 + 7 = 12$  at the back and is joined to commutator segment 5 at the front. Next, the conductor No. 12 is joined to commutator segment  $5 + 7 = 12$  ( $\because Y_C = 7$ ) to which is joined conductor No.  $12 + 7 = 19$ . Continuing this way, we come back to conductor No. 5 from where we started. Hence, the winding closes upon itself.

\* If we take 8, then the pitches would be :  $Y_B = 9$  and  $Y_F = 7$  or  $Y_B = 7$  and  $Y_F = 9$ . Incidentally, if  $Y_A = Y_C$  is taken as 7, armature will rotate in one direction and if  $Y_C = 8$ , it will rotate in the opposite direction.

The simple winding table is as under :

<b>Back Connections</b>	→	<b>Front Connections</b>
1 to $(1 + 7) = 8$	→	8 to $(8 + 7) = 15$
15 to $(15 + 7) = 22$	→	22 to $(22 + 7) = 29$
29 to $(29 + 7) = 36 = (36 - 30) = 6$	→	6 to $(6 + 7) = 13$
13 to $(13 + 7) = 20$	→	20 to $(20 + 7) = 27$
27 to $(27 + 7) = 34 = (34 - 30) = 4$	→	4 to $(4 + 7) = 11$
11 to $(11 + 7) = 18$	→	18 to $(18 + 7) = 25$
25 to $(25 + 7) = 32 = (32 - 30) = 2$	→	2 to $(2 + 7) = 9$
9 to $(9 + 7) = 16$	→	16 to $(16 + 7) = 23$
23 to $(23 + 7) = 30$	→	30 to $(30 + 7) = 37 = (37 - 30) = 7$
7 to $(7 + 7) = 14$	→	14 to $(14 + 7) = 21$
21 to $(21 + 7) = 28$	→	28 to $(28 + 7) = 35 = (35 - 30) = 5$
5 to $(5 + 7) = 12$	→	12 to $(12 + 7) = 19$
19 to $(19 + 7) = 26$	→	26 to $(26 + 7) = 33 = (33 - 30) = 3$
3 to $(3 + 7) = 10$	→	10 to $(10 + 7) = 17$
17 to $(17 + 7) = 24$	→	24 to $(24 + 7) = 31 = (31 - 30) = 1$

Since we come back to the conductor No. 1 from where we started, the winding gets closed at this stage.

### Brush Position

Location of brush position in wave-winding is slightly difficult. In Fig. 26.36 conductors are supposed to be moving from left to right over the poles. By applying Fleming's Right-hand rule, the directions of the induced e.m.fs in various armature conductors can be found. The directions shown in the figure have been found in this manner. In the lower part of Fig. 26.36 is shown the equivalent ring or spiral diagram which is very helpful in understanding the formation of various parallel paths in the armature. It is seen that the winding is electrically divided into two portions. One portion consists of conductors lying between points  $N$  and  $L$  and the other of conductors lying between  $N$  and  $M$ . In the first portion, the general trend of the induced e.m.fs. is from left to right whereas in the second portion it is from right to left. Hence, in general, there are only two parallel paths through the winding, so that two brushes are required, one positive and one negative.

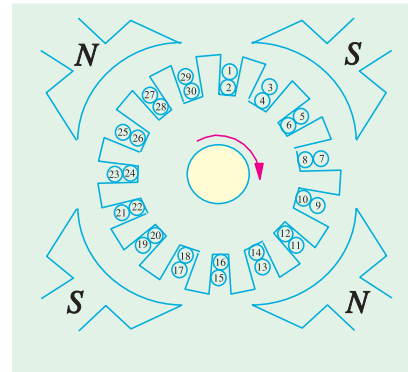

Fig. 26.37

From the equivalent ring diagram, it is seen that point  $N$  is the separating point of the e.m.fs. induced in the two portions of the winding. Hence, this fixes the position of the negative brush. But as it is at the back and not at the commutator end of the armature, the negative brush has two alternative positions *i.e.* either at point  $P$  or  $Q$ . These points on the equivalent diagram correspond to commutator segments No. 3 and 11.

Now, we will find the position of the positive brush. It is found that there are two meeting points of the induced e.m.fs. *i.e.* points  $L$  and  $M$  but both these points are at the back or non-commutator end of the armature. These two points are separated by one loop only, namely, the loop composed of conductors 2 and 9, hence the middle point  $R$  of this loop fixes the position of the positive brush, which should be placed in touch with commutator segment No. 7. We find that for one position of the +ve brush, there are two alternative positions for the -ve brush.

Taking the +ve brush at point  $R$  and negative brush at point  $P$ , the winding is seen to be divided into the following two paths.

Fig. 26.38

In path 1 (Fig. 26.36) it is found that e.m.f. in conductor 9 is in opposition to the general trend of e.m.fs. in the other conductors comprising this path. Similarly, in path 2, the e.m.f. in conductor 2 is in position to the direction of e.m.fs. in the path as a whole. However, this will make no difference because these conductors lie almost in the interpolar gap and, therefore e.m.fs. in these conductors are negligible.

Fig. 26.39

Again, take the case of conductors 2 and 9 situated between points *L* and *M*. Since the armature conductors are in continuous motion over the pole faces, their positions as shown in the figure are only instantaneous. Keeping in this mind, it is obvious that conductor 2 is about to move from the influence of *S*-pole to that of the next *N*-pole. Hence, the e.m.f. in it is at the point of reversing. However, conductor 9 has already passed the position of reversal, hence its e.m.f. will not reverse,

rather it will increase in magnitude gradually. It means that in a very short interval, point  $M$  will

Fig. 26.40

become the meeting point of the e.m.f.s. But as it lies at the back of the armature, there are two alternative positions for the +ve brush *i.e.* either point  $R$  which has already been considered or point  $S$  which corresponds to commutator segment 14. This is the second alternative position of the positive brush. Arguing in the same way, it can be shown that after another short interval of time, the alternative position of the positive brush will shift from segment 14 to segment 15. Therefore, if one positive brush is in the contact with segment 7, then the second positive brush if used, should be in touch with both segments 14 and 15.

It may be noted that if brushes are placed in both alternative positions for both positive and negative (*i.e.* if in all, 4 brushes are used, two +ve and two -ve), then the effect is merely to short-circuit the loop lying between brushes of the same polarity. This is shown in Fig. 26.40 where it will also be noted that irrespective of whether only two or four brushes are used, the number of parallel paths through the armature winding is still two.

Summarizing the above facts, we get

1. Only two brushes are necessary, though their number may be equal to the number of poles.
2. The number of parallel paths through the armature winding is two irrespective of the number of generator poles. That is why this winding is sometimes called 'two-circuit' or 'series' winding.
3. The generator e.m.f. is equal to the e.m.f. induced in any one of the two parallel paths. If  $e_{av}$  is the e.m.f. induced/conductor, then generator e.m.f. is  $E_g = e_{av} \times Z/2$ .
4. The equivalent armature resistance is nearly one-fourth of the total resistance of the armature winding.
5. If  $I_a$  is the total armature current, then current carried by each path or conductor is obviously  $I_a/2$  whatever the number of poles.

### 26.29. Dummy or Idle Coils

These are used with wave-winding and are resorted to when the requirements of the winding are not met by the standard armature punchings available in armature-winding shops. These dummy coils do not influence the electrical characteristics of the winding because they are not connected to the commutator. They are exactly similar to the other coils except that their ends are cut short and taped. They are there simply to provide mechanical balance for the armature because an armature having some slots without windings would be out of balance mechanically. For example, suppose number of armature slots is 15, each containing 4 sides and the number of poles is 4. For a simplex wave-windings,

Dummy coils

$$Y_A = \frac{Z \pm 2}{P} = \frac{60 \pm 2}{4}$$

which does not come out to be an integer (Art. 26.28) as required by this winding. However, if we make one coil dummy so that we have 58 active conductors, then

$$Y_A = \frac{58 \pm 2}{4} = 14 \text{ or } 15$$

This makes the winding possible.

### 26.30. Uses of Lap and Wave Windings

The advantage of the wave winding is that, for a given number of poles and armature conductors, it gives more e.m.f. than the lap winding. Conversely, for the same e.m.f., lap winding would require large number of conductors which will result in higher winding cost and less efficient utilization of space in the armature slots. Hence, wave winding is suitable for small generators especially those meant for 500-600 V circuits.

Another advantage is that in wave winding, equalizing connections are not necessary whereas in a lap winding they definitely are. It is so because each of the two paths contains conductors lying under all the poles whereas in lap-wound armatures, each of the  $P$  parallel paths contains conductors which lie under one pair of poles. Any inequality of pole fluxes affects two paths equally, hence their induced e.m.fs. are equal. In lap-wound armatures, unequal voltages are produced which set up a circulating current that produces sparking at brushes.

However, when large currents are required, it is necessary to use lap winding, because it gives more parallel paths.

Hence, lap winding is suitable for comparatively low-voltage but high-current generators whereas wave-winding is used for high-voltage, low-current machines.

#### Tutorial Problem No. 26.1

1. Write down the winding table for a 2-layer simplex lap-winding for a 4-pole d.c. generator having (a) 20 slots and (b) 13 slots. What are the back and front pitches as measured in terms of armature conductors?

[Hint : (a) No. of conductors = 40 ;  $Y_B = 11$  and  $Y_F = -9$ ] (Elect. Engineering, Madras Univ. 1978)

- (b) No. of conductors = 26 ;  $Y_B = 7$  ;  $Y_F = -5$

2. With a simplex 2-layer wave winding having 26 conductors and 4-poles, write down the winding table. What will be the front and back pitches of the winding?

[Hint :  $Y_F = 7$  and  $Y_B = 5$ ] (Electric Machinery-I, Madras Univ. Nov. 1979)

3. Is it possible to get simplex wave winding for a 4-pole d.c. machine with 28 conductors? Explain the reason for your answer. **[No, it would contain only 4 conductors]**

4. State for what type of winding each of the following armatures could be used and whether the winding must be four or six-pole if no dummy coils are to be used (a) 33 slots, 165 commutator segments (b) 64 slots, 256 commutator segments (c) 65 slots, 260 commutator segments.

**[(a) 4-pole lap with commutator pitch 82 or 83 or 6-pole lap.**

**(b) 4-pole lap or 6-pole wave with commutator pitch 85.**

**(c) 6-pole wave with commutator pitch 87.]**

### 26.31. Types of Generators

Generators are usually classified according to the way in which their fields are excited. Generators may be divided into (a) separately-excited generators and (b) self-excited generators.

(a) **Separately-excited** generators are those whose field magnets are energised from an independent external source of d.c. current. It is shown diagrammatically in Fig. 26.41.

(b) **Self-excited generators** are those whose field magnets are energised by the current produced by the generators themselves. Due to residual magnetism, there is always present some flux in the poles. When the armature is rotated, some e.m.f. and hence some induced current is produced which is partly or fully passed through the field coils thereby strengthening the residual pole flux.

There are three types of self-excited generators named according to the manner in which their field coils (or windings) are connected to the armature.

#### (i) Shunt wound

The field windings are connected across or in parallel with the armature conductors and have the full voltage of the generator applied across them (Fig. 26.42).

#### (ii) Series Wound

Fig. 26.41

Fig. 26.42

Fig. 26.43

In this case, the field windings are joined in series with the armature conductors (Fig. 26.43). As they carry full load current, they consist of relatively few turns of thick wire or strips. Such generators are rarely used except for special purposes *i.e.* as boosters etc.

#### (iii) Compound Wound

It is a combination of a few series and a few shunt windings and can be either short-shunt or long-shunt as shown in Fig. 26.44 (a) and

Fig. 26.44

(b) respectively. In a compound generator, the shunt field is stronger than the series field. When series field *aids* the shunt field, generator is said to be *cumulatively-compounded*. On the other hand if series field *opposes* the shunt field, the generator is said to be *differentially compounded*. Various types of d.c. generators have been shown separately in Fig. 26.45.

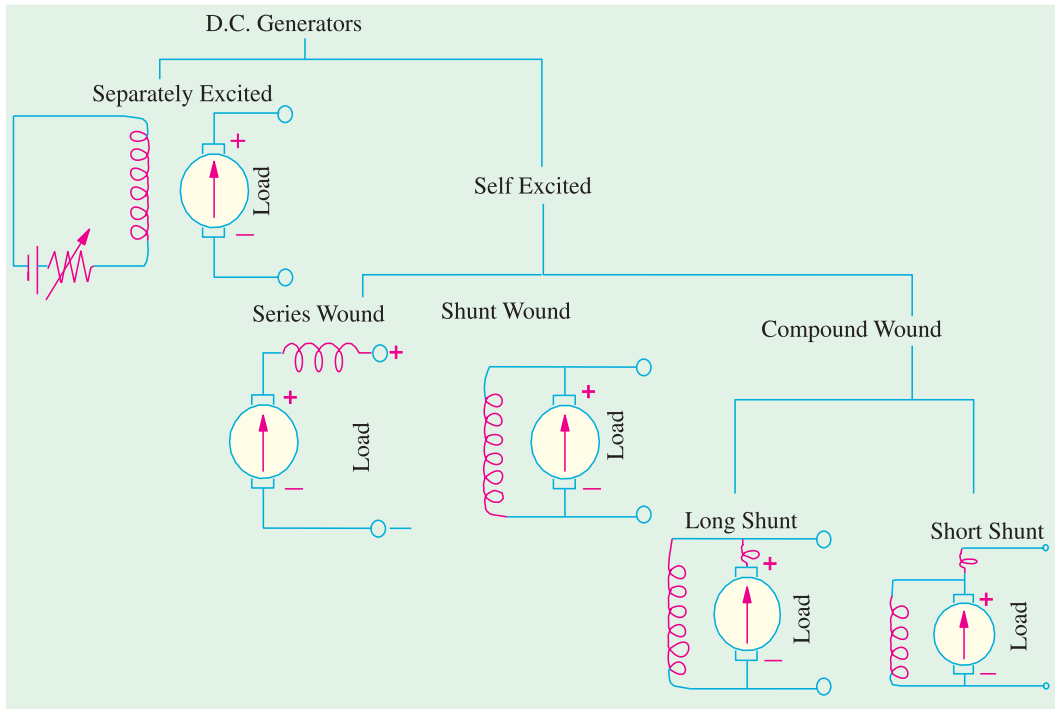

Fig. 26.45

### 26.32. Brush Contact Drop

It is the voltage drop over the brush contact resistance when current passes from commutator segments to brushes and finally to the external load. Its value depends on the amount of current and the value of contact resistance. This drop is usually small and includes brushes of both polarities. However, in practice, the brush contact drop is assumed to have following constant values for all loads.

0.5 V for metal-graphite brushes.

2.0 V for carbon brushes.

**Example 26.3.** A shunt generator delivers 450 A at 230 V and the resistance of the shunt field and armature are 50 Ω and 0.03 Ω respectively. Calculate the generated e.m.f.

**Solution.** Generator circuit is shown in Fig. 26.46.

Current through shunt field winding is

$$I_{sh} = 230/50 = 4.6 \text{ A}$$

Load current  $I = 450 \text{ A}$

$$\begin{aligned} \therefore \text{Armature current } I_a &= I + I_{sh} \\ &= 450 + 4.6 = 454.6 \text{ A} \end{aligned}$$

Armature voltage drop

$$I_a R_a = 454.6 \times 0.03 = \mathbf{13.6 \text{ V}}$$

Fig. 26.46

Now  $E_g = \text{terminal voltage} + \text{armature drop}$   
 $= V + I_a R_a$

$\therefore$  e.m.f. generated in the armature

$$E_g = 230 + 13.6 = \mathbf{243.6 \text{ V}}$$

**Example 26.4.** A long-shunt compound generator delivers a load current of 50 A at 500 V and has armature, series field and shunt field resistances of 0.05  $\Omega$ , 0.03  $\Omega$  and 250  $\Omega$  respectively. Calculate the generated voltage and the armature current. Allow 1 V per brush for contact drop.

(Elect. Science 1, Allahabad Univ. 1992)

**Solution.** Generator circuit is shown in Fig. 26.47.

$$I_{sh} = 500/250 = 2 \text{ A}$$

Current through armature and series winding is  
 $= 50 + 2 = 52 \text{ A}$

Voltage drop on series field winding  
 $= 52 \times 0.03 = 1.56 \text{ V}$

Armature voltage drop  
 $I_a R_a = 52 \times 0.05 = 2.6 \text{ V}$

Drop at brushes =  $2 \times 1 = 2 \text{ V}$

Now,  $E_g = V + I_a R_a + \text{series drop} + \text{brush drop}$   
 $= 500 + 2.6 + 1.56 + 2 = \mathbf{506.16 \text{ V}}$

Fig. 26.47

**Example 26.5.** A short-shunt compound generator delivers a load current of 30 A at 220 V, and has armature, series-field and shunt-field resistances of 0.05  $\Omega$ , 0.30  $\Omega$  and 200  $\Omega$  respectively. Calculate the induced e.m.f. and the armature current. Allow 1.0 V per brush for contact drop.

(AMIE Sec. B. Elect. Machines 1991)

**Solution.** Generator circuit diagram is shown in Fig. 26.48.

Voltage drop in series winding =  $30 \times 0.3 = 9 \text{ V}$

Voltage across shunt winding =  $220 + 9 = 229 \text{ V}$

$$I_{sh} = 229/200 = 1.145 \text{ A}$$

$$I_a = 30 + 1.145 = 31.145 \text{ A}$$

$$I_a R_a = 31.145 \times 0.05 = 1.56 \text{ V}$$

Brush drop =  $2 \times 1 = 2 \text{ V}$

$$E_g = V + \text{series drop} + \text{brush drop} + I_a R_a$$

$$= 220 + 9 + 2 + 1.56 = 232.56 \text{ V}$$

Fig. 26.48

**Example 26.6.** In a long-shunt compound generator, the terminal voltage is 230 V when generator delivers 150 A. Determine (i) induced e.m.f. (ii) total power generated and (iii) distribution of this power. Given that shunt field, series field, diverter and armature resistance are 92  $\Omega$ , 0.015  $\Omega$ , 0.03  $\Omega$  and 0.032  $\Omega$  respectively.

(Elect. Technology-II, Gwalior Univ. 1987)

**Solution.**  $I_{sh} = 230/92 = 2.5 \text{ A}$   
 $I_a = 150 + 2.5 = 152.5 \text{ A}$

Fig. 26.49

Power lost in series field and diverter  
 Power dissipated in shunt winding  
 Power delivered to load

Since series field resistance and diverter resistances are in parallel (Fig. 26.49) their combined resistance is  
 $= 0.03 \times 0.015 / 0.045 = 0.01 \Omega$

Total armature circuit resistance is  
 $= 0.032 + 0.01 = 0.042 \Omega$

Voltage drop =  $152.5 \times 0.042 = 6.4 \text{ V}$

(i) Voltage generated by armature

$$E_g = 230 + 6.4 = 236.4 \text{ V}$$

(ii) Total power generated in armature

$$E_g I_a = 236.4 \times 152.5 = 36,051 \text{ W}$$

(iii) Power lost in armature

$$I_a^2 R_a = 152.5^2 \times 0.032 = 744 \text{ W}$$

$$= 152.5^2 \times 0.01 = 232 \text{ W}$$

$$= V I_{sh} = 230 \times 0.01 = 575 \text{ W}$$

$$= 230 \times 150 = 34500 \text{ W}$$

$$\text{Total} = 36,051 \text{ W.}$$

**Example 26.7.** The following information is given for a 300-kW, 600-V, long-shunt compound generator : Shunt field resistance = 75 Ω, armature resistance including brush resistance = 0.03 Ω, commutating field winding resistance = 0.011 Ω, series field resistance = 0.012 Ω, diverter resistance = 0.036 Ω. When the machine is delivering full load, calculate the voltage and power generated by the armature.

(Elect. Engg-II, Pune Univ. Nov. 1989)

**Solution.** Power output = 300,000 W

$$\text{Output current} = 300,000 / 600 = 500 \text{ A}$$

$$I_{sh} = 600 / 75 = 8 \text{ A,}$$

$$I_a = 500 + 8 = 508 \text{ A}$$

Since the series field resistance and diverter resistance are in parallel (Fig. 26.50) their combined resistance is

$$= \frac{0.012 \times 0.036}{0.048} = 0.009 \Omega$$

Total armature circuit resistance

$$= 0.03 - 0.011 + 0.009 = 0.05 \Omega$$

$$\text{Voltage drop} = 508 \times 0.05 = 25.4 \text{ V}$$

Voltage generated by armature

$$= 600 + 25.4 = 625.4 \text{ V}$$

$$\text{Power generated} = 625.4 \times 508 = 317,700$$

$$W = 317.7 \text{ kW}$$

Fig. 26.50

### 26.33. Generated E.M.F. or E.M.F. Equation of a Generator

Let  $\Phi$  = flux/pole in weber

$Z$  = total number of armature conductors

- = No. of slots  $\times$  No. of conductors/slot
- $P$  = No. of generator poles
- $A$  = No. of parallel paths in armature
- $N$  = armature rotation in revolutions per minute (r.p.m.)
- $E$  = e.m.f. induced in any parallel path in armature

Generated e.m.f.  $E_g$  = e.m.f. generated in any one of the parallel paths *i.e.*  $E$ .

$$\text{Average e.m.f. generated/conductor} = \frac{d\Phi}{dt} \text{ volt } (\because n = 1)$$

Now, flux cut/conductor in one revolution  $d\Phi = \Phi PWb$

No. of revolutions/second =  $N/60$   $\therefore$  Time for one revolution,  $dt = 60/N$  second

Hence, according to Faraday's Laws of Electromagnetic Induction,

$$\text{E.M.F. generated/conductor} = \frac{d\Phi}{dt} = \frac{\Phi PN}{60} \text{ volt}$$

### For a simplex wave-wound generator

No. of parallel paths = 2

No. of conductors (in series) in one path =  $Z/2$

$$\therefore \text{E.M.F. generated/path} = \frac{\Phi PN}{60} \times \frac{Z}{2} = \frac{\Phi ZPN}{120} \text{ volt}$$

### For a simplex lap-wound generator

No. of parallel paths =  $P$

No. of conductors (in series) in one path =  $Z/P$

$$\therefore \text{E.M.F. generated/path} = \frac{\Phi PN}{60} \times \frac{Z}{P} = \frac{\Phi ZN}{60} \text{ volt}$$

$$\text{In general generated e.m.f. } E_g = \frac{\Phi ZN}{60} \times \left(\frac{P}{A}\right) \text{ volt}$$

where

$$A = 2\text{-for simplex wave-winding}$$

$$= P\text{-for simplex lap-winding}$$

$$\text{Also, } E_g = \frac{1}{2\pi} \cdot \left(\frac{2\pi N}{60}\right) \Phi Z \left(\frac{P}{A}\right) = \frac{\omega \Phi Z}{2\pi} \left(\frac{P}{A}\right) \text{ volt} - \omega \text{ in rad/s}$$

For a given d.c. machine,  $Z$ ,  $P$  and  $A$  are constant. Hence, putting  $K_a = ZP/A$ , we get

$$E_g = K_a \Phi N \text{ volts--where } N \text{ is in r.p.s.}$$

**Example 26.8.** A four-pole generator, having wave-wound armature winding has 51 slots, each slot containing 20 conductors. What will be the voltage generated in the machine when driven at 1500 rpm assuming the flux per pole to be 7.0 mWb? (**Elect. Machines-I, Allahabad Univ. 1993**)

$$\text{Solution. } E_g = \frac{\Phi ZN}{60} \left(\frac{P}{A}\right) \text{ volts}$$

$$\text{Here, } \Phi = 7 \times 10^{-3} \text{ Wb, } Z = 51 \times 20 = 1020, A = P = 4, N = 1500 \text{ r.p.m.}$$

$$\therefore E_g = \frac{7 \times 10^{-3} \times 1020 \times 1500}{60} \left(\frac{4}{2}\right) = \mathbf{178.5 \text{ V}}$$

**Example 26.9.** An 8-pole d.c. generator has 500 armature conductors, and a useful flux of 0.05 Wb per pole. What will be the e.m.f. generated if it is lap-connected and runs at 1200 rpm? What must be the speed at which it is to be driven produce the same e.m.f. if it is wave-wound?

(**U.P. Technical Univ. 2001**)

**Solution.** With lap-winding,  $P = a = 8$

$$E = \phi (N/60) (P/a)$$

$$= 0.05 \times 500 \times 20 \times 1,$$

$$= 500 \text{ volts}$$

for lap-winding

If it is wave-wound,  $P = 8, a = 2, P/a = 4$

and  $E = 0.05 \times 500 \times (N/60) \times 4$

For  $E = 500 \text{ volts}, N = 300 \text{ rpm}$

Hence, with wave-winding, it must be driven at 300 rpm to generate 500 volts.

**Additional Explanation.** Assume 1 amp as the current per conductor.

(a) Lap-wound, 1200 rpm : 500 V per coil-group, 8 groups in parallel

Net output current = 8 amp as in Fig. 26.51 (a).

Power output = 4 kW

(b) Wave-wound, 300 rpm : 2 groups in parallel, one group has four coils in series, as shown in Fig. 26.51 (b).

Total power-output is now

$$500 \times 2 = 1000 \text{ W.}$$

It is reduced to one fourth, being proportional to the speed.

Fig. 26.51(a)

Fig. 26.51(b)

**Example 26.10.** A d.c. shunt generator has an induced voltage on open-circuit of 127 volts. When the machine is on load, the terminal voltage is 120 volts. Find the load current if the field-circuit resistance is 15 ohms and the armature-resistance is 0.02 ohm. Ignore armature reaction.

(Madras University April 1997, Bharathiar University Nov. 1997)

**Solution.**

**Note :** Even though the question does not specify some conditions, the solution given here is based on correct approach to deal with the case.

**Generator on no load :**

As shown in Fig. 26.52 (a), the machine is run at  $N_1$  rpm.

$$E_g = 127 + 8.47 \times 0.02 = 127.17 \text{ volts}$$

As in Fig. 26.52 (b),  $I_f = 8 \text{ amp}$

$E_g$  can be 127.17 volts, if the speed is increased to  $N_2$  rpm, such that

$$8.47 N_1 = 8N_2, \text{ or } N_2 = \frac{8.47}{8} N_1 = 1.05875 N_1$$

Thus the effect due to 5.875% decrease in flux is compensated by 5.875% increase in speed.

Fig. 26.52

If  $E_g$  is assumed to remain unaltered at 127.17 V,

$$I_a = \frac{127.17 - 120}{0.02} = 358.5 \text{ amp}$$

Hence,

$$I_L = 358.5 - 8 = 350.5 \text{ amp.}$$

**Example 26.11(a).** An 8-pole d.c. shunt generator with 778 wave-connected armature conductors and running at 500 r.p.m. supplies a load of  $12.5 \Omega$  resistance at terminal voltage of 50 V. The armature resistance is  $0.24 \Omega$  and the field resistance is  $250 \Omega$ . Find the armature current, the induced e.m.f. and the flux per pole.

(Electrical Engg-I, Bombay Univ. 1988)

**Solution.** The circuit is shown in Fig. 26.53

$$\text{Load current} = V/R = 250/12.5 = 20 \text{ A}$$

$$\text{Shunt current} = 250/250 = 1 \text{ A}$$

$$\text{Armature current} = 20 + 1 = \mathbf{21 \text{ A}}$$

$$\text{Induced e.m.f.} = 250 + (21 \times 0.24) = \mathbf{255.04 \text{ V}}$$

$$\text{Now, } E_g = \frac{\Phi ZN}{60} \times \left(\frac{P}{A}\right)$$

$$\therefore 255.04 = \frac{\Phi \times 778 \times 500}{60} \left(\frac{8}{2}\right)$$

$$\therefore \Phi = \mathbf{9.83 \text{ mWb}}$$

Fig. 26.53

**Example 26.11(b).** A 4-pole lap-connected armature of a d.c. shunt generator is required to supply the loads connected in parallel :

(1) 5 kW Geyser at 250 V, and

(2) 2.5 kW Lighting load also at 250 V.

The Generator has an armature resistance of 0.2 ohm and a field resistance of 250 ohms. The armature has 120 conductors in the slots and runs at 1000 rpm. Allowing 1 V per brush for contact drops and neglecting friction, find

(1) Flux per pole, (2) Armature-current per parallel path. (Nagpur University Nov. 1998)

**Solution.** Geyser current =  $5000/250 = 20$  A  
 Current for Lighting =  $2500/250 = 10$  A  
 Total current = 30 A  
 Field Current for Generator = 1 A  
 Hence, Armature Current = 31 A  
 Armature resistance drop =  $31 \times 0.2 = 6.2$  volts  
 Generated e.m.f. =  $250 + 6.2 + 2 = 258.2$  V,

since  $E = V_t + I_a r_a + \text{Total brush contact drop}$   
 For a 4-pole lap-connected armature,

Number of parallel paths = number of poles = 4

(1) The flux per pole is obtained from the emf equation

$$\begin{aligned} 258.2 &= [\phi Z N/60] \times (p/a) \\ &= [\phi \times 120 \times 1000/60] \times (4/4) \\ &= 2000 \phi \\ \phi &= 129.1 \text{ mWb} \end{aligned}$$

(2) Armature current per parallel path =  $31/4 = 7.75$  A.

**Example 26.12.** A separately excited generator, when running at 1000 r.p.m. supplied 200 A at 125 V. What will be the load current when the speed drops to 800 r.p.m. if  $I_f$  is unchanged? Given that the armature resistance = 0.04 ohm and brush drop = 2 V.

(Elect. Machines Nagpur Univ. 1993)

**Solution.** The load resistance  $R = 125/200 = 0.625 \Omega$ , in Fig. 26.54.

$$E_{g1} = 125 + 200 \times 0.04 + 2 = 135 \text{ V}; N_1 = 1000 \text{ r.p.m.}$$

$$\text{At } 800 \text{ r.p.m. } E_{g2} = 135 \times 800/1000 = 108 \text{ V}$$

If  $I$  is the new load current, then terminal voltage  $V$  is given by

$$V = 108 - 0.04 I - 2 = 106 - 0.04 I$$

$$\therefore I = V/R = (106 - 0.04 I)/0.635; I = 159.4 \text{ A}$$

Fig. 26.54

**Example 26.13.** A 4-pole, 900 r.p.m. d.c. machine has a terminal voltage of 220 V and an induced voltage of 240 V at rated speed. The armature circuit resistance is  $0.2 \Omega$ . Is the machine operating as a generator or a motor? Compute the armature current and the number of armature coils if the air-gap flux/pole is 10 mWb and the armature turns per coil are 8. The armature is wave-wound.  
 (Elect. Machines AMIE Sec. B 1990)

**Solution.** Since the induced voltage  $E$  is more than the terminal voltage  $v$ , the machine is working as a generator.

$$E - V = I_a R_a \text{ or } 240 - 220 = I_a \times 0.2; I_a = 100 \text{ A}$$

$$\text{Now, } E_b = ZN(P/A) \text{ or } 240 = 10 \times 10^{-3} \times z \times (900/600) (4/2); Z = 8000$$

Since there are 8 turns in a coil, it means there are 16 active conductors/coil. Hence, the number of coils =  $8000/16 = 500$ .

**Example 26.14.** In a 120 V compound generator, the resistances of the armature, shunt and series windings are  $0.06 \Omega$ ,  $25 \Omega$  and  $0.04 \Omega$  respectively. The load current is 100 A at 120 V. Find the induced e.m.f. and the armature current when the machine is connected as (i) long-shunt and as (ii) short-shunt. How will the ampere-turns of the series field be changed in (i) if a diverter of  $0.1 \text{ ohm}$  be connected in parallel with the series winding? Neglect brush contact drop and ignore armature reaction.  
 (Elect. Machines AMIE Sec. B, 1992)

**Solution. (i) Long Shunt [Fig. 26.55 (a)]**

$$I_{sh} = 120/25 = 4.8 \text{ A} ; I = 100 \text{ A} ; I_a = 104.8 \text{ A}$$

Voltage drop in series winding =  $104.8 \times 0.04 = 4.19 \text{ V}$

Armature voltage drop =  $104.8 \times 0.06 = 6.29 \text{ V}$

$\therefore E_g = 120 + 3.19 + 6.29 = 130.5 \text{ V}$

**(ii) Short Shunt [Fig. 26.55 (c)]**

Voltage drop in series winding =  $100 \times 0.04 = 4 \text{ V}$

Voltage across shunt winding =  $120 + 4 = 124 \text{ V}$

$\therefore I_{sh} = 124/25 = 5 \text{ A} ; \therefore I_a = 100 + 5 = 105 \text{ A}$

Armature voltage drop =  $105 \times 0.06 = 6.3 \text{ V}$

$E_g = 120 + 5 + 4 = 129 \text{ V}$

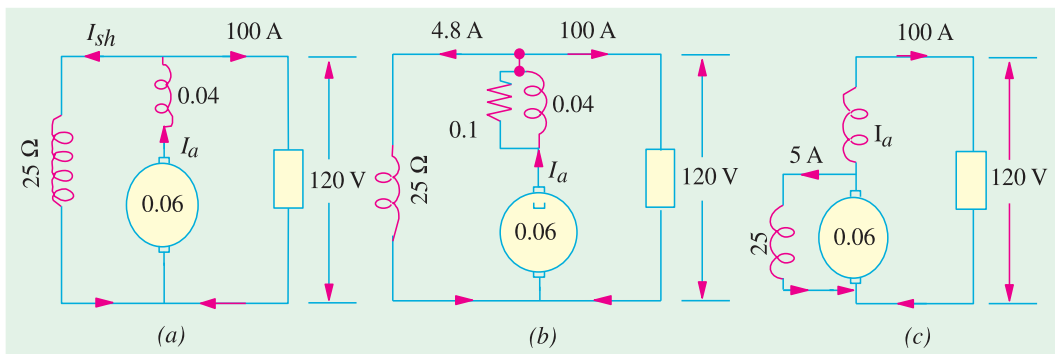

Fig. 26.55

When a diverter of  $0.1 \Omega$  is connected in parallel with the series winding, the diagram becomes as shown in Fig. 26.55 (b). As per current-divider rule, the current through the series winding is  $= 104.8 \times 0.1/(0.1 + 0.04) = 74.86 \text{ A}$ . It means that the series field current has decreased from an original value of  $104.8 \text{ A}$  to  $74.86 \text{ A}$ . Since No. of turns in the series winding remains the same, the change in series field ampere-turns would be the same as the change in the field current. Hence, the percentage decrease in the series field ampere-turns  $= (74.86 - 104.8) \times 100/104.8 = -28.6\%$ .

**Example 26.15.** A 4-pole, long-shunt lap-wound generator supplies 25 kW at a terminal voltage of 500 V. The armature resistance is 0.03 ohm, series field resistance is 0.04 ohm and shunt field resistance is 200 ohm. The brush drop may be taken as 1.0 V. Determine the e.m.f. generated.

Calculate also the No. of conductors if the speed is 1200 r.p.m. and flux per pole is 0.02 weber. Neglect armature reaction.

(Elec. Engineering-I, St. Patel Univ. 1986)

**Solution.**  $I = 25,000/500 = 50 \text{ A}$ ,  $I_{sh} = 500/200 = 2.5 \text{ A}$  (Fig. 26.56)

$$I_a = I + I_{sh} = 50 + 2.5 = 52.5 \text{ A}$$

Series field drop =  $52.5 \times 0.04 = 2.1 \text{ V}$

Armature drop =  $52.5 \times 0.03 = 1.575 \text{ V}$

Brush drop =  $2 \times 1 = 2 \text{ V}$

Generated e.m.f.,  $E_g = 500 + 2.1 + 1.575 + 2 = 505.67 \text{ V}$

Fig. 26.56

Now, 
$$E_g = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right)$$
 or 
$$505.67 = \frac{0.02 \times Z \times 1200}{60} \left( \frac{4}{4} \right), Z = 1264$$

**Example 26.16.** A 4-pole d.c. generator runs at 750 r.p.m. and generates an e.m.f. of 240 V. The armature is wave-wound and has 792 conductors. If the total flux from each pole is 0.0145 Wb, what is the leakage coefficient ?

**Solution.** Formula used :

$$E = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right) \text{ volt} \quad \therefore 240 = \frac{\Phi \times 750 \times 792}{60} \times \frac{4}{2}$$

$\therefore$  Working flux/pole,  $\Phi = 0.0121 \text{ Wb}$  ; Total flux/pole = 0.0145 Wb

$\therefore$  Leakage coefficient  $\lambda = \frac{\text{total flux/pole}}{\text{working flux/pole}} = \frac{0.0145}{0.0121} = 1.2$

**Example 26.17.** A 4-pole, lap-wound, d.c. shunt generator has a useful flux per pole of 0.07 Wb. The armature winding consists of 220 turns each of 0.004  $\Omega$  resistance. Calculate the terminal voltage when running at 900 r.p.m. if the armature current is 50 A.

**Solution.** Since each turn has two sides,

$$Z = 220 \times 2 = 400 ; N = 900 \text{ r.p.m.} ; \Phi = 0.07 \text{ Wb} ; P = A = 4$$

$\therefore E_g = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right) = \frac{0.07 \times 440 \times 900}{60} \times \left( \frac{4}{4} \right) = 462 \text{ volt}$

Total resistance of 220 turns (or 440 conductors) =  $220 \times 0.004 = 0.88 \Omega$

Since there are 4 parallel paths in armature,

$\therefore$  Resistance of each path =  $0.88/4 = 0.22 \Omega$

Now, there are four such resistances in parallel each of value 0.22  $\Omega$

$\therefore$  Armature resistance,  $R_a = 0.22/4 = 0.055 \Omega$

Armature drop =  $I_a R_a = 50 \times 0.055 = 2.75 \text{ V}$

Now, terminal voltage  $V = E_g - I_a R_a = 462 - 2.75 = 459.25 \text{ volt.}$

**Example 26.18.** A 4-pole, lap-wound, long-shunt, d.c. compound generator has useful flux per pole of 0.07 Wb. The armature winding consists of 220 turns and the resistance per turn is 0.004 ohms. Calculate the terminal voltage if the resistance of shunt and series field are 100 ohms and 0.02 ohms respectively ; when the generator is running at 900 r.p.m. with armature current of 50 A. Also calculate the power output in kW for the generator.

(Basic Elect. Machine Nagpur Univ. 1993)

**Solution.** 
$$E_b = \frac{0.07 \times (220 \times 2) \times 900}{60} \times \left( \frac{4}{4} \right) = 462 \text{ V}$$

As found in Ex. 26.17,  $R_a = 0.055 \Omega$

Arm. circuit resistance =  $R_a + R_{se} = 0.055 + 0.02 = 0.075 \Omega$

Arm. circuit drop =  $50 \times 0.075 = 3.75 \text{ V}$

$V = 462 - 3.75 = 458.25 \text{ V}$ , in Fig. 26.57.

$I_{sh} = 458.25/100 = 4.58 \text{ A}$  ;  $I = 50 - 4.58 = 45.42 \text{ A}$

Output =  $VI = 458.25 \times 45.42 = 20,814 \text{ W} = 20.814 \text{ kW}$

Fig. 26.57

**Example 26.19.** A separately excited d.c. generator, when running at 1200 r.p.m. supplies 200 A at 125 V to a circuit of constant resistance. What will be the current when the speed is dropped to 1000 r.p.m. and the field current is reduced to 80%? Armature resistance, 0.04 Ω and total drop at brushes, 2 V. Ignore saturation and armature reaction.

(Elect. Machines AMIE Sec. B, 1991)

Fig. 26.58

**Solution.** We will find the generated e.m.f. when the load current is 200 A.

$$E_{g1} = V + \text{brush drop} + I_a R_a = 125 + 200 \times 0.04 = 135 \text{ V, in Fig. 26.58.}$$

$$\text{Now, } E_{g1} \propto \Phi_1 N_1 \text{ and } E_{g2} \propto \Phi_2 N_2$$

$$\therefore \frac{E_{g2}}{E_{g1}} = \frac{\Phi_2 N_2}{\Phi_1 N_1}$$

$$\text{or } \frac{E_{g2}}{135} = 0.8 \times \frac{1000}{1200} = 90 \text{ V}$$

**Example 26.20(a).** A 4-pole, d.c. shunt generator with a shunt field resistance of 100 Ω and an armature resistance of 1 Ω has 378 wave-connected conductors in its armature. The flux per pole is 0.02 Wb. If a load resistance of 10 Ω is connected across the armature terminals and the generator is driven at 1000 r.p.m., calculate the power absorbed by the load.

(Elect. Technology, Hyderabad Univ. 1991)

**Solution.** Induced e.m.f. in the generator is

$$E_s = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right) \text{ volt}$$

$$= \frac{0.02 \times 378 \times 1000}{60} \left( \frac{4}{2} \right) = 252 \text{ volt}$$

Now, let  $V$  be the terminal voltage i.e. the voltage available across the load as well as the shunt resistance (Fig. 26.59).

$$\text{Load current} = V/10 \text{ A and Shunt current} = V/100 \text{ A}$$

$$\text{Armature current} = \frac{V}{10} + \frac{V}{100} = \frac{11V}{100}$$

$$\text{Now, } V = E_g - \text{armature drop}$$

$$\therefore V = 252 - 1 \times \frac{11V}{100} \quad \therefore V = 227 \text{ volt}$$

$$\text{Load current} = 227/10 = 22.7 \text{ A, Power absorbed by the load is} = 227 \times 22.7 = 5,153 \text{ W}$$

**Example 26.20(b).** A four-pole, lap-wound shunt generator has 300 armature-conductors and a flux/pole of 0.1 Wb. It runs at 1000 r.p.m. The armature and field-resistances are 0.2 ohm and 125 ohms respectively. Calculate the terminal voltage when it is loaded to take a load current of 90 A. Ignore armature reaction.

Fig. 26.59

**Solution.** First, the e.m.f. should be calculated

$$E = 0.1 \times 300 \times (1000/60) \times (4/4) = 500 \text{ volts}$$

The field current  $500/125 = 4$  amp

For the load current of 90 amp, armature current = 94 amp

$$I_a r_a = 94 \times 0.20 = 18.8 \text{ volts}$$

$$\text{Terminal voltage, } V = 500 - 18.8 = 481.2 \text{ volts}$$

**Note :** Due to the reduction in terminal voltage (as an effect of loading), the shunt field current tends to decrease, which will further reduce  $V$ . To compensate for this, either increase the speed slightly or decrease the shunt-field-circuit resistance slightly.

**Example 26.21(a).** A 6-pole dc generator runs at 1200 r.p.m. on no-load and has a generated e.m.f. of 250 V. Its armature diameter is 350 mm and the radial air-gap between the field poles and the armature is 3 mm. The axial length of the field poles is 260 mm and the field pole effective coverage is 80% including fringing. If the armature has 96 coils having 3 turns per coil and is wound duplex lap, calculate (a) flux per pole (b) effective pole arc length and (c) average air-gap flux density.

Fig. 26.60

**Solution. (a)**  $Z = (96 \times 3) \times 2 = 576$ ,  $P = 6$ ,  $A = P \times \text{plex} = 6 \times 2 = 12$ ,  $N = 1200$  r.p.m.

$$\therefore 250 = \frac{\Phi \times 576 \times 1200}{6} \left( \frac{6}{12} \right); \quad \therefore \Phi = 0.0434 \text{ Wb}$$

(b) Inner diameter of the pole shoe circle is  $= 350 + 6 = 356$  mm.

Since there are 6 poles, the net field pole flux coverage is 80% of one-sixth of the pole shoe circle. Hence, the effective pole arc length is

$$= \frac{1}{6} \times \pi d \times 0.8 = \frac{1}{6} \times \pi \times 356 \times 0.8 = 149 \text{ mm} = 0.149 \text{ m.}$$

(c) Pole surface area = pole shoe arc  $\times$  axial length of the pole (Fig. 26.60).

$$= 0.149 \times 0.260 = 0.03874 \text{ mm}^2$$

$\therefore$  Flux density  $B = 0.0434/0.03874 = 1.12$  T

**Example 26.21(b).** A 4-pole d.c. Generator with 1200 conductors generates 250 volts on open circuit, when driven at 500 rpm. The pole-shoes have a bore of 35 cm and the ratio of pole-arc to pole pitch is 0.7, while, the length of the pole shoe is 20 cm. Find the mean flux density in the airgap.

(Bharthiar Univ. Nov. 1972 & April 1998)

**Solution.** For a diameter of 35, 4-pole machine has a pole-pitch of  $(35\pi/4) = 27.5$  cm

Since pole-arc/pole pitch is 0.7, Pole-arc  $= 0.7 \times 27.5 = 19.25$  cm

Pole area  $= 19.25 \times 20 = 385$  sq. cm.

Substituting in the e.m.f. equation,  $250 = (\phi ZN/60) (p/a)$

For Lap-winding, in the case,  $p = a = 4$

Hence, flux/pole  $= (250 \times 60)/(1200 \times 500) = 0.025$  Wb

This flux is uniformly distributed over the pole-area.

Mean flux density in the air-gap  $= (0.025)/(385 \times 10^{-4}) = 0.65$  Wb/m<sup>2</sup>

**Example 26.21(c).** A four-pole lap-wound dc shunt generator having 80 slots with 10 conductors per slot generates at no-load an e.m.f. of 400 V, when run at 1000 rpm. How will you obtain a generated open-circuit voltage of 220 V?

(Nagpur University November 1996)

**Solution. (i)** Keeping operating speed at 1000 rpm only, **change the flux per pole**

The O.C. e.m.f. is given by  $E = (\phi ZN/60) \times (P/a)$

For the given operating conditions,

$$400 = \phi \times (80 \times 10) \times (1000/60) \times (4/4)$$

which gives  $\phi = 30$  mWb

When speed is kept constant at 1000 rpm only,

$$E \propto \phi$$

Or to get 220 V on O.C.,  $\phi_2 = (220/400) \times 30 \text{ mWb} = 16.5 \text{ mWb}$

Thus, by increasing the shunt-field-circuit resistance with the help of adding external rheostatic, the current in the field-circuit is decreased so as to decrease the flux to 16.5 mWb.

(ii) Keep same flux per pole, change the speed.

If  $\phi$  is held constant at 30 mWb, an O.C. e.m.f. of 220 V is obtained at a speed of  $N$  r.p.m., given by

$$220 = 30 \times 10^{-3} \times 800 \times N/60, \quad N = 550 \text{ rpm}$$

At 220 V, the flux can be maintained at 30 mWb provided the field **current is unchanged**.

$$400/R_{f1} = 200/R_{f2}$$

$$\text{or} \quad R_{f2} = 0.55 R_{f1}$$

Thus, the field circuit resistance must be reduced to the new value of  $0.55 R_A$  in order to obtain 30 mWb of flux per pole from a voltage of 220 V.

(iii) Any other combination of proper speed and flux/pole can be chosen and worked out on similar lines.

**Example 26.21 (d).** A short-shunt d.c. compound generator supplies 200 A at 100 V. The resistance of armature, series field and shunt field windings are 0.04, 0.03 and 60 ohms respectively. Find the emf generated. Also find the emf generated if same machine is connected as a long-shunt machine. (Nagpur University, April 1998)

**Solution.** With short-shunt connection, shown in Fig. 26.61 (a).

$$V_a = \text{armature terminal voltage} = 100 + (200 \times 0.03) = 106 \text{ V}$$

$$\text{Shunt field current} = 106/60 = 1.767 \text{ amp}$$

$$\text{Armature current} = I_a = 200 + 1.767 = 201.767 \text{ amp}$$

$$\text{Armature induced e.m.f.} = 106 + (201.767 \times 0.04) = 114.07 \text{ volts}$$

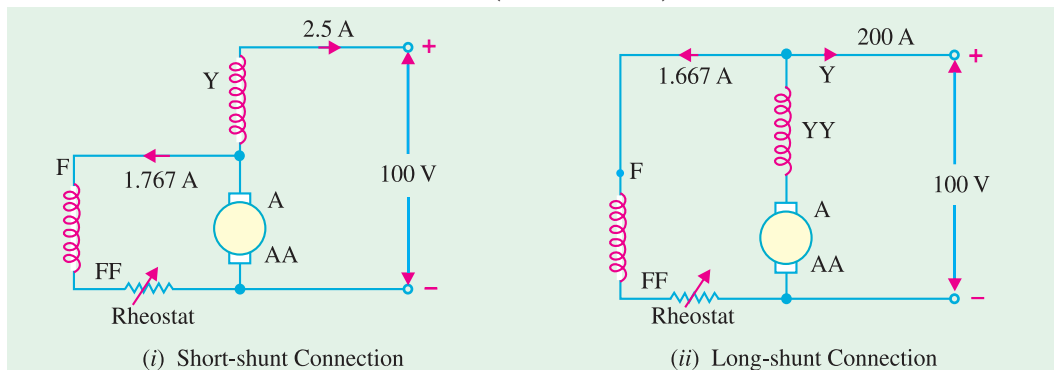

Fig. 26.61(a)

Now, with long-shunt connection shown in Fig. 26.61 (b),

$$\text{Shunt field current} = 100/60 = 1.667 \text{ amp}$$

$$\text{Armature current} = 201.667 \text{ amp}$$

Total voltage drop in armature and series field winding

$$= 201.667 (0.04 + 0.03) = 14.12 \text{ volts}$$

$$\text{Armature induced e.m.f.} = 100 + 14.12 = 114.12 \text{ volts}$$

**Note :** In case of long shunt connection, the generator has to develop the e.m.f. with shunt field current slightly reduced, compared to the case of short shunt connection. However, the series field winding carries a slightly higher current in latter case. Still, in practice, slight speed adjustment (or shunt field rheostatic variation) may be required to get this e.m.f., as per calculations done above.

**Example 26.22.** A long shunt dynamo running at 1000 r.p.m. supplies 20 kW at a terminal voltage of 220 V. The resistance of armature, shunt field, and series field are 0.04, 110 and 0.05 ohm respectively. Overall efficiency at the above load is 85%. Find :

- Copper loss,
- Iron and friction loss,
- Torque developed by the prime mover.

(Amravati University 1999)

Fig. 26.61(b)

**Solution.**  $I_L$ , Load current =  $\frac{20,000}{220} = 90.91$  amp

Shunt field current,  $I_f = \frac{220}{110} = 2$  amp

Armature current,  $I_a = 92.91$  amp

Input power =  $20,000/0.85 = 23529$  watts

Total losses in the machine = Input – Output =  $23529 - 20,000 = 3529$  watts

**(i) Copper losses :**

Power loss in series field-winding + armature winding =  $92.91^2 \times 0.09$  watts = 777 watts

Power-loss in shunt field circuit :  $2^2 \times 110 = 440$  watts

Total copper losses =  $777 + 400 = 1217$  watts

**(ii) Iron and friction losses = Total losses – Copper losses**

=  $3529 - 1217 = 2312$  watts

**(iii) Let  $T$  = Torque developed by the prime-mover**

At 1000 r.p.m., angular speed,  $\omega = 2\pi \times 1000/60 = 104.67$  rad./sec

$T \times \omega =$  Input power

$\therefore T = 23529/104.67 = 224.8$  Nw-m

## 26.34. Iron Loss in Armature

Due to the rotation of the iron core of the armature in the magnetic flux of the field poles, there are some losses taking place continuously in the core and are known as Iron Losses or Core Losses. Iron losses consist of **(i) Hysteresis** loss and **(ii) Eddy Current** loss.

**(i) Hysteresis Loss ( $W_h$ )**

This loss is due to the reversal of magnetisation of the armature core. Every portion of the rotating core passes under  $N$  and  $S$  pole alternately, thereby attaining  $S$  and  $N$  polarity respectively. The core undergoes one complete cycle of magnetic reversal after passing under one pair of poles. If  $P$  is the number of poles and  $N$ , the armature speed in r.p.m., then frequency of magnetic reversals is  $f = PN/120$ .

The loss depends upon the volume and grade of iron, maximum value of flux density  $B_{max}$  and frequency of magnetic reversals. For normal flux densities (*i.e.* upto  $1.5 \text{ Wb/m}^2$ ), hysteresis loss is given by **Steinmetz** formula. According to this formula,

$$W_h = \eta B_{max}^{1.6} f V \text{ watts}$$

where

$V =$  volume of the core in  $\text{m}^3$

$\eta =$  Steinmetz hysteresis coefficient.

Value of  $\eta$  for :

Good dynamo sheet steel =  $502 \text{ J/m}^3$ , Silicon steel =  $191 \text{ J/m}^2$ , Hard Cast steel =  $7040 \text{ J/m}^3$ , Cast steel =  $750 - 3000 \text{ J/m}^3$  and Cast iron =  $2700 - 4000 \text{ J/m}^3$ .

### (ii) Eddy Current Loss ( $W_e$ )

When the armature core rotates, it also cuts the magnetic flux. Hence, an e.m.f. is induced in the body of the core according to the laws of electromagnetic induction. This e.m.f. though small, sets up large current in the body of the core due to its small resistance. This current is known as eddy current. The power loss due to the flow of this current is known as eddy current loss. This loss would be considerable if solid iron core were used. In order to reduce this loss and the consequent heating of the core to a small value, the core is built up of thin laminations, which are stacked and then riveted at right angles to the path of the eddy currents. These core laminations are insulated from each other by a thin coating of varnish.

The effect of laminations is shown in Fig. 26.62. Due to the core body being one continuous solid iron piece [Fig. 26.62 (a)], the magnitude of eddy currents is large. As armature cross-sectional area is large, its resistance is very small, hence eddy current loss is large. In Fig. 26.62 (b), the same core has been split up into thin circular discs insulated from each other. It is seen that now each current path, being of much less cross-section, has a very high resistance. Hence, magnitude of eddy currents is reduced considerably thereby drastically reducing eddy current loss.

Fig. 26.62

It is found that eddy current loss  $W_e$  is given by the following relation :

$$W_e = KB_{\max}^2 f^2 t^2 V^2 \text{ watt}$$

where  $B_{\max}$  = maximum flux density  $f$  = frequency of magnetic reversals  
 $t$  = thickness of each lamination  $V$  = volume of armature core.

It is seen from above that this loss varies directly as the square of the thickness of laminations, hence it should be kept as small as possible. Another point to note is that  $W_h \propto f$  but  $W_e \propto f^2$ . This fact makes it possible to separate the two losses experimentally if so desired.

As said earlier, these iron losses if allowed to take place unchecked not only reduce the efficiency of the generator but also raise the temperature of the core. As the output of the machines is limited, in most cases, by the temperature rise, these losses have to be kept as small as is economically possible.

Eddy current loss is reduced by using laminated core but hysteresis loss cannot be reduced this way. For reducing the hysteresis loss, those metals are chosen for the armature core which have a low hysteresis coefficient. Generally, special silicon steels such as stalloys are used which not only have a low hysteresis coefficient but which also possess high electrical resistivity.

## 26.35. Total Loss in a D.C. Generator

The various losses occurring in a generator can be sub-divided as follows :

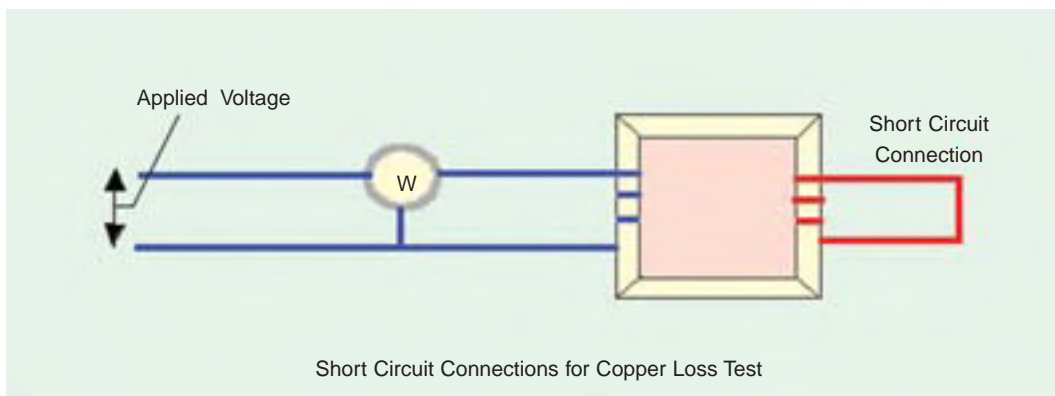

### (a) Copper Losses

(i) Armature copper loss =  $I_a^2 R_a$

[Note :  $E_g I_a$  is the power output from armature.]

where  $R_a$  = resistance of armature and interpoles and series field winding etc.

This loss is about 30 to 40% of full-load losses.

(ii) Field copper loss. In the case of shunt generators, it is practically constant and  $I_{sh}^2 R_{sh}$  (or  $VI_{sh}$ ). In the case of series generator, it is  $I_{se}^2 R_{se}$  where  $R_{se}$  is resistance of the series field winding.

This loss is about 20 to 30% of F.L. losses.

(iii) The loss due to brush contact resistance. It is usually included in the armature copper loss.

(b) **Magnetic Losses** (also known as iron or core losses),

(i) hysteresis loss,  $W_h \propto B_{\max}^{1.6} f$  and (ii) eddy current loss,  $W_e \propto B_{\max}^2 f^2$

These losses are practically constant for shunt and compound-wound generators, because in their case, field current is approximately constant.

Both these losses total up to about 20 to 30% of F.L. losses.

(c) **Mechanical Losses.** These consist of :

(i) friction loss at bearings and commutator.

(ii) air-friction or windage loss of rotating armature.

These are about 10 to 20% of F.L. Losses.

The total losses in a d.c. generator are summarized below :

### 26.36. Stray Losses

Usually, magnetic and mechanical losses are collectively known as **Stray Losses**. These are also known as rotational losses for obvious reasons.

### 26.37. Constant or Standing Losses

As said above, field Cu loss is constant for shunt and compound generators. Hence, stray losses and shunt Cu loss are constant in their case. These losses are together known as standing or constant losses  $W_c$ .

Hence, for shunt and compound generators,

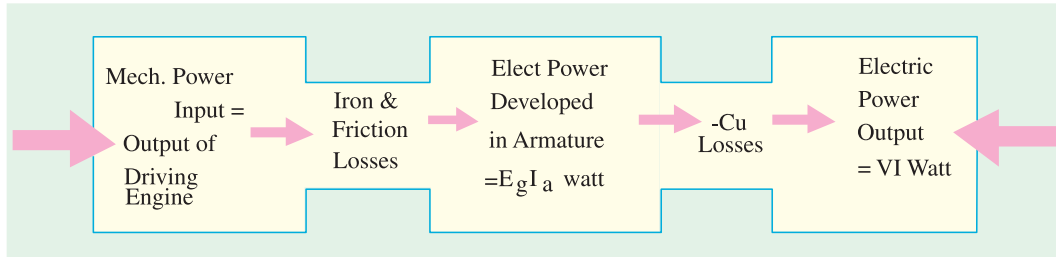

$$\text{Total loss} = \text{armature copper loss} + W_c = I_a^2 R_a + W_c = (I + I_{sh})^2 R_a + W_c$$

Armature Cu loss  $I_a^2 R_a$  is known as variable loss because it varies with the load current.

Total loss = variable loss + constant losses  $W_c$

### 26.38. Power Stages

Various power stages in the case of a d.c. generator are shown below :

Following are the three generator efficiencies :

#### 1. Mechanical Efficiency

$$\eta_m = \frac{B}{A} = \frac{\text{total watts generated in armature}}{\text{mechanical power supplied}} = \frac{E_g I_a}{\text{output of driving engine}}$$

#### 2. Electrical Efficiency

$$\eta_e = \frac{C}{B} = \frac{\text{watts available in load circuit}}{\text{total watts generated}} = \frac{VI}{E_g I_a}$$

#### 3. Overall or Commercial Efficiency

$$\eta_c = \frac{C}{A} = \frac{\text{watts available in load circuit}}{\text{mechanical power supplied}}$$

It is obvious that overall efficiency  $\eta_c = \eta_m \times \eta_e$ . For good generators, its value may be as high as 95%.

**Note.** Unless specified otherwise, commercial efficiency is always to be understood.

### 26.39. Condition for Maximum Efficiency

Generator output =  $VI$

Generator input = output + losses

$$= VI + I_a^2 R_a + W_c = VI + (I + I_{sh})^2 R_a + W_c \quad (\because I_a = I + I_{sh})$$

However, if  $I_{sh}$  is negligible as compared to load current, then  $I_a = I$  (approx.)

$$\begin{aligned} \therefore \eta &= \frac{\text{output}}{\text{input}} = \frac{VI}{VI + I_a^2 R_a + W_c} = \frac{VI}{VI + I^2 R_a + W_c} \quad (\because I_a = I) \\ &= \frac{1}{1 + \left( \frac{IR_a}{V} + \frac{W_c}{VI} \right)} \end{aligned}$$

Now, efficiency is maximum when denominator is minimum *i.e.* when

$$\frac{d}{dI} \left( \frac{IR_a}{V} + \frac{W_c}{VI} \right) = 0 \text{ or } \frac{R_a}{V} - \frac{W_c}{VI^2} = 0 \text{ or } I^2 R_a = W_c$$

Hence, generator efficiency is maximum when

**Variable loss = constant loss.**

The load current corresponding to maximum efficiency is given by the relation.

$$I^2 R_a = W_c \text{ or } I = \sqrt{\frac{W_c}{R_a}}$$

Variation of  $\eta$  with load current is shown in Fig. 26.63.

**Example 26.23.** A 10 kW, 250 V, d.c., 6-pole shunt generator runs at 1000 r.p.m. when delivering full-load. The armature has 534 lap-connected conductors. Full-load Cu loss is 0.64 kW. The total brush drop is 1 volt. Determine the flux per pole. Neglect shunt current.

(Elect. Engg. & Electronics, M.S. Univ./Baroda 1987)

**Solution.** Since shunt current is negligible, there is no shunt Cu loss. The copper loss occurs in armature only.

$$I = I_a = 10,000/250 = 40 \text{ A}; I_a^2 R_a = \text{Arm. Cu loss} \text{ or } 40^2 \times R_a = 0.64 \times 10^3; R_a = 0.4 \Omega$$

$$I_a R_a \text{ drop} = 0.4 \times 40 = 16 \text{ V}; \text{Brush drop} = 2 \times 1 = 2 \text{ V}$$

$$\therefore \text{Generated e.m.f. } E_g = 250 + 16 + 1 = 267 \text{ V}$$

$$\text{Now, } E_g = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right) \text{ volt } \therefore 267 = \frac{\Phi \times 534 \times 1000}{60} \left( \frac{6}{6} \right) \therefore \Phi = 30 \times 10^{-3} \text{ Wb} = \mathbf{30 \text{ mWb}}$$

**Example 26.24(a).** A shunt generator delivers 195 A at terminal p.d. of 250 V. The armature resistance and shunt field resistance are 0.02  $\Omega$  and 50  $\Omega$  respectively. The iron and friction losses equal 950 W. Find

- (a) E.M.F. generated (b) Cu losses (c) output of the prime motor  
(d) commercial, mechanical and electrical efficiencies.

(Elect. Machines-I, Nagpur Univ. 1991)

**Solution. (a)**  $I_{sh} = 250/50 = 5 \text{ A}; I_a = 195 + 5 = 200 \text{ A}$

Armature voltage drop =  $I_a R_a = 200 \times 0.02 = 4 \text{ V}$

$\therefore$  Generated e.m.f. =  $250 + 4 = \mathbf{254 \text{ V}}$

**(b)** Armature Cu loss =  $I_a^2 R_a = 200^2 \times 0.02 = 800 \text{ W}$

Shunt Cu loss =  $V.I_{sh} = 250 \times 5 = 1250 \text{ W}$

$\therefore$  Total Cu loss =  $1250 + 800 = \mathbf{2050 \text{ W}}$

**(c)** Stray losses = 950 W ; Total losses =  $2050 + 950 = 3000 \text{ W}$

Output =  $250 \times 195 = 48,750 \text{ W}$  ; Input =  $48,750 + 3000 = 51750 \text{ W}$

$\therefore$  Output of prime mover =  $\mathbf{51,750 \text{ W}}$

**(d)** Generator input = 51,750 W ; Stray losses = 950 W

Electrical power produced in armature =  $51,750 - 950 = 50,800$

$\eta_m = (50,800/51,750) \times 100 = \mathbf{98.2\%}$

Electrical or Cu losses = 2050 W

$\therefore \eta_e = \frac{48,750}{48,750 + 2,050} \times 100 = \mathbf{95.9\%}$

and  $\eta_c = (48,750/51,750) \times 100 = \mathbf{94.2\%}$

Fig. 26.63

**Example 26.24(b).** A 500 V, D.C. shunt motor draws a line current of 5 amps, on light load. If armature resistance is 0.15 ohm, and field resistance is 200 ohms, determine the efficiency of the machine running as a generator, delivering a load current of 40 Amp.

(Bharathiar Univ. Nov. 1997)

**Solution. (i)** As a motor, on Light load, out of 5 Amps of line current, 2.5 Amps are required for field circuit and 2.5 Amps are required for armature. Neglecting copper-loss in armature at no load (since it works out to be just one watt), the armature-power goes towards armature-core-loss and no-load mechanical loss at the rated speed. This amounts to  $(500 \times 2.5) = 1250$  watts.

**(ii)** As a generator, for a line current of 40 Amp, the total current for the armature is 42.5 amp. Output of generator =  $500 \times 40 \times 10^{-3} = 20$  kW

$$\begin{aligned} \text{Total losses as a generator} &= 1250 + \text{field copper-loss} + \text{arm. copper-loss} \\ &= (1250 + 1250 + 42.5^2 \times 0.15) \text{ watts} = 2.771 \text{ kW} \end{aligned}$$

$$\text{Efficiency} = \frac{20}{20 + 2.771} \times 100 = 87.83\%$$

**Example 26.25.** A shunt generator has a F.L. current of 196 A at 220 V. The stray losses are 720 W and the shunt field coil resistance is 55  $\Omega$ . If it has a F.L. efficiency of 88%, find the armature resistance. Also, find the load current corresponding to maximum efficiency.

(Electrical Technology Punjab Univ. Nov. 1988)

$$\begin{aligned} \text{Solution.} \quad \text{Output} &= 220 \times 196 = 43,120 \text{ W} ; \eta = 88\% \text{ (overall efficiency)} \\ \text{Electrical input} &= 43,120/0.88 = 49,000 \text{ W} \\ \text{Total losses} &= 49,000 - 43,120 = 5,880 \text{ W} \\ \text{Shunt field current} &= 220/55 = 4 \text{ A} \quad \therefore I_a = 196 + 4 = 200 \text{ A} \\ \therefore \text{Shunt Cu loss} &= 220 \times 4 = 880 \text{ W} ; \text{Stray losses} = 720 \text{ W} \\ \text{Constant losses} &= 880 + 720 = 1,600 \\ \therefore \text{Armature Cu loss} &= 5,880 - 1,600 = 4,280 \text{ W} \\ \therefore I_a^2 R_a &= 4,280 \text{ W} \\ 200^2 R_a &= 4,280 \quad \text{or} \quad R_a = 4,280/200 \times 200 = \mathbf{0.107 \Omega} \end{aligned}$$

For maximum efficiency,

$$I^2 R_a = \text{constant losses} = 1,600 \text{ W} ; I = \sqrt{1,600/0.107} = \mathbf{122.34 \text{ A}}$$

**Example 26.26.** A long-shunt dynamo running at 1000 r.p.m. supplies 22 kW at a terminal voltage of 220 V. The resistances of armature, shunt field and the series field are 0.05, 110 and 0.06  $\Omega$  respectively. The overall efficiency at the above load is 88%. Find (a) Cu losses (b) iron and friction losses (c) the torque exerted by the prime mover.

(Elect. Machinery-I, Bangalore Univ. 1987)

**Solution.** The generator is shown in Fig. 26.64.

$$\begin{aligned} I_{sh} &= 220/110 = 2 \text{ A} \\ I &= 22,000/220 = 100 \text{ A}, \\ I_a &= 102 \text{ A} \end{aligned}$$

Drop in series field winding =  $102 \times 0.06 = 6.12$  V

$$\text{(a)} \quad I_a^2 R_a = 102^2 \times 0.05 = 520.2 \text{ W}$$

$$\text{Series field loss} = 102^2 \times 0.06 = 624.3 \text{ W}$$

$$\text{Shunt field loss} = 4 \times 110 = 440 \text{ W}$$

Fig. 26.64

$$\text{Total Cu losses} = 520.2 + 624.3 + 440 = \mathbf{1584.5 \text{ W}}$$

$$(b) \quad \text{Output} = 22,000 \text{ W}; \text{ Input} = 22,000/0.88 = 25,000 \text{ W}$$

$$\therefore \text{Total losses} = 25,000 - 22,000 = 3,000 \text{ W}$$

$$\therefore \text{Iron and friction losses} = 3,000 - 1,584.5 = \mathbf{1,415.5 \text{ W}}$$

$$\text{Now, } T \times \frac{2\pi N}{60} = 25,000; \quad T = \frac{25,000 \times 60}{1,000 \times 6.284} = \mathbf{238.74 \text{ N-m}}$$

**Example 26.27.** A 4-pole d.c. generator is delivering 20 A to a load of 10  $\Omega$ . If the armature resistance is 0.5  $\Omega$  and the shunt field resistance is 50  $\Omega$ , calculate the induced e.m.f. and the efficiency of the machine. Allow a drop of 1 V per brush.

(Electrical Technology-I, Osmania Univ., 1990)

**Solution.** Terminal voltage =  $20 \times 10 = 200 \text{ V}$

$$I_{sh} = 200/50 = 4 \text{ A}; I_a = 20 + 4 = 24 \text{ A}$$

$$I_a R_a = 24 \times 0.5 = 12 \text{ V}; \text{ Brush drop} = 2 \times 1 = 2 \text{ V}$$

$$\therefore E_g = 200 + 12 + 2 = \mathbf{214 \text{ V}}, \text{ as in Fig. 26.65.}$$

Since iron and friction losses are not given, only electrical efficiency of the machine can be found out.

Total power generated in the armature

$$= 214 \times 24 = 5,136 \text{ W}$$

$$\text{Useful output} = 200 \times 20 = 4,000 \text{ W}$$

$$\therefore \eta_e = 4,000/5,136 = 0.779 \text{ or } \mathbf{77.9\%}$$

Fig. 26.65

**Example 26.28.** A long-shunt compound-wound generator gives 240 volts at F.L. output of 100 A. The resistances of various windings of the machine are : armature (including brush contact) 0.1  $\Omega$ , series field 0.02  $\Omega$ , interpole field 0.025  $\Omega$ , shunt field (including regulating resistance) 100  $\Omega$ . The iron loss at F.L. is 1000 W ; windage and friction losses total 500 W. Calculate F.L. efficiency of the machine.

(Electrical Machinery-I, Indore Univ. 1989)

**Solution.** Output =  $240 \times 100 = 24,000 \text{ W}$

Total armature circuit resistance =  $0.1 + 0.02 + 0.025 = 0.145 \Omega$

$$I_{sh} = 240/100 = 2.4 \text{ A} \quad \therefore I_a = 100 + 2.4 = 102.4 \text{ A}$$

$$\therefore \text{Armature circuit copper loss} = 102.4^2 \times 0.145 = 1,521 \text{ W}$$

$$\text{Shunt field copper loss} = 2.4 \times 240 = 576 \text{ W}$$

$$\text{Iron loss} = 1000 \text{ W}; \text{ Friction loss} = 500 \text{ W}$$

$$\text{Total loss} = 1,521 + 1,500 + 576 = 3,597 \text{ W}; \eta = \frac{24,000}{24,000 + 3,597} = 0.87 = \mathbf{87\%}$$

**Example 26.29.** In a d.c. machine the total iron loss is 8 kW at its rated speed and excitation. If excitation remains the same, but speed is reduced by 25%, the total iron loss is found to be 5 kW. Calculate the hysteresis and eddy current losses at (i) full speed (ii) half the rated speed.

(Similar Example, JNTU, Hyderabad, 2000)

**Solution.** We have seen in Art. 26.32 that

$$W_h \propto f \text{ and } W_e \propto f^2$$

Since  $f$ , the frequency of reversal of magnetization, is directly proportional to the armature speed,

$$W_h \propto N \text{ and } W_e \propto N^2$$

$\therefore$   $W_h = A \times N$  and  $W_e = BN^2$ , where  $A$  and  $B$  are constants.  
 Total loss  $W = W_h + W_e = AN + BN^2$

Let the full rated speed be 1.

$$\text{Then } 8 = A \times 1 + B \times 1^2 \quad \text{or} \quad 8 = A + B \quad \dots(i)$$

Now, when speed is 75% of full rated speed, then

$$5 = A \times (0.75) + B(0.75)^2 \quad \dots(ii)$$

Multiplying (i) by 0.75 and subtracting (ii) from it, we get

$$0.1875 B = 1 \quad \therefore B = 1/0.1875 = 5.33$$

**kW**

Substituting this value in (i) above

$$8 = 5.33 + A \quad \therefore A = 2.67 \text{ kW}$$

$$(i) \quad W_h \text{ at rated speed} = 2.67 \text{ kW}, \quad W_e \text{ at rated speed} = 5.33 \text{ kW}$$

$$(ii) \quad W_h \text{ at half the rated speed} = 2.67 \times 0.5 = 1.335 \text{ kW}$$

$$W_e \text{ at half the rated speed} = 5.33 \times 0.5^2 = 1.3325 \text{ kW}$$

**Example 26.30.** The hysteresis and eddy current losses in a d.c. machine running at 1000 r.p.m. are 250 W and 100 W respectively. If the flux remains constant, at what speed will be total iron losses be halved? **(Electrical Machines-I, Gujarat Univ. 1989)**

**Solution.** Total loss  $W = W_h + W_e = AN + BN^2$

$$\text{Now, } W_h = 250 \text{ W} \quad \therefore A \times (1000/60) = 250; \quad A = 15$$

$$W_e = 100 \text{ W} \quad \therefore B \times (1000/60)^2 = 100; \quad B = 9/25$$

Let  $N$  be the new speed in r.p.s. at which total loss is one half of the loss at 1000 r.p.m. New loss =  $(250 + 100)/2 = 175 \text{ W}$

$$\therefore 175 = 15N + (9/25)N^2 \quad \text{or} \quad 9N^2 + 375N - 4,375 = 0$$

$$\therefore N = \frac{-375 \pm \sqrt{375^2 + 36 \times 4,375}}{2 \times 9} = \frac{-375 \pm 546}{18} = 9.5 \text{ r.p.s} = 570 \text{ r.p.m.}^*$$

**Note.** It may be noted that at the new speed,  $W_h = 250 \times (570/100) = 142.5 \text{ W}$  and  $W_e = 100 \times (570/1000)^2 = 32.5 \text{ W}$ . Total loss =  $142.5 + 32.5 = 175 \text{ W}$ .

**Example 26.31.** A d.c. shunt generator has a full load output of 10 kW at a terminal voltage of 240 V. The armature and the shunt field winding resistances are 0.6 and 160 ohms respectively. The sum of the mechanical and core-losses is 500 W. Calculate the power required, in kW, at the driving shaft at full load, and the corresponding efficiency. **(Nagpur University November 99)**

**Solution.** Field current =  $\frac{240}{160} = 1.5 \text{ amp}$ , Load current =  $\frac{10,000}{240} = 41.67 \text{ amp}$

$$\text{Armature current} = 41.67 + 1.5 = 43.17 \text{ amp}$$

$$\text{Field copper losses} = 360 \text{ W}, \text{ Armature copper losses} = 43.17^2 \times 0.6 = 1118 \text{ W}$$

$$\text{Total losses in kW} = 0.36 + 1,118 + 0.50 = 1,978 \text{ kW}$$

Hence, Power input at the shaft = 11.978 kW

$$\text{Efficiency} = \frac{10}{11.978} \times 100\% = 83.5\%$$

\* The negative value has been rejected—being mathematically absurd.

**Example 26.32.** A long shunt d.c. compound generator delivers 110 kW at 220 V.

If  $r_a = 0.01$  ohm,  $r_{se} = 0.002$  ohm, and shunt field has a resistance of 110 ohms, calculate the value of the induced e.m.f. (Bharathithasan University Nov. 1997)

**Solution.** Load current =  $110 \times 1000/220$   
= 500 A

Shunt field current =  $220/110 = 2$  A

Armature current = 502 A

$$r_a + r_{se} = 0.012 \text{ ohm}$$

$$E_a = 220 + [502 \times (0.012)]$$

$$= 226.024 \text{ V}$$

Fig. 26.66. Long-shunt d.c. compound generator

**Example 26.33.** The armature of a four-pole d.c. shunt generator is lap-wound and generates 216 V when running at 600 r.p.m. Armature has 144 slots, with 6 conductors per slot. If this armature is rewound, wave-connected, find the e.m.f. generated with the same flux per pole but running at 500 r.p.m. (Bharathithasan University April 1997)

**Solution.** Total number of armature conductors =  $Z = 144 \times 6 = 864$

For a Lap winding, number of parallel paths in armature = number of poles

In the e.m.f. equation,  $E = (\phi ZN/60) (P/a)$

Since  $P = a$

$$E = \phi ZN/60$$

$$216 = \phi \times 864 \times 600/60 = 8640\phi$$

Hence  $\phi = 25$  milli-webers

If the armature is rewound with wave-connection, number of parallel paths = 2.

Hence, at 500 r.p.m., with 25 mWb as the flux per pole.

$$\begin{aligned} \text{the armature emf} &= (25 \times 10^{-3} \times 864 \times 500/60) \times 4/2 \\ &= 25 \times 864 \times 0.50 \times 2/60 \\ &= 360 \text{ volts} \end{aligned}$$

**Additional note :**

**Extension to Que :** Comment on the armature output power in the two cases.

**Solution.** Assumption is that field side is suitably modified in the two cases.

**Case (i) :** Lap-wound Machine at 600 r.p.m.

Armature e.m.f. = 216 V

Let each armature-conductor be rated to carry a current of 10 amp.

In simple lap-wound machines, since a four-pole machine has four parallel paths in armature, the total armature output-current is 40 amp.

Hence, armature-output-power =  $216 \times 40 \times 10^{-3} = 8.64$  kW

**Case (ii) :** Wave-wound machine, at 500 r.p.m.

Armature e.m.f. = 360 V

Due to wave-winding, number of parallel paths in armature = 2

Hence, the total armature output current = 20 amp

Thus, Armature Electrical output-power =  $360 \times 20 \times 10^{-3} = 7.2 \text{ kW}$

**Observation.** With same flux per pole, the armature power outputs will be in the proportion of the speeds, as  $(7.2/8.64) = 5/6$ .

**Further Conclusion.** In case of common speed for comparing Electrical Outputs with same machine once lap-wound and next wave-wound, there is no difference in the two cases. Lap-wound machine has lower voltage and higher current while the wave-wound machine has higher voltage and lower current.

**Example 26.34.** A 4-pole, Lap-connected d.c. machine has an armature resistance of 0.15 ohm. Find the armature resistance of the machine is rewound for wave-connection.

(Bharthiar Univ. Nov. 1997)

**Solution.** A 4-pole lap-winding has 4 parallel paths in armature. If it is rewound for wave-connection, the resistance across the terminal becomes  $(4 \times 0.15) = 0.6 \text{ ohm}$ , as it obvious from Fig. 26.67.

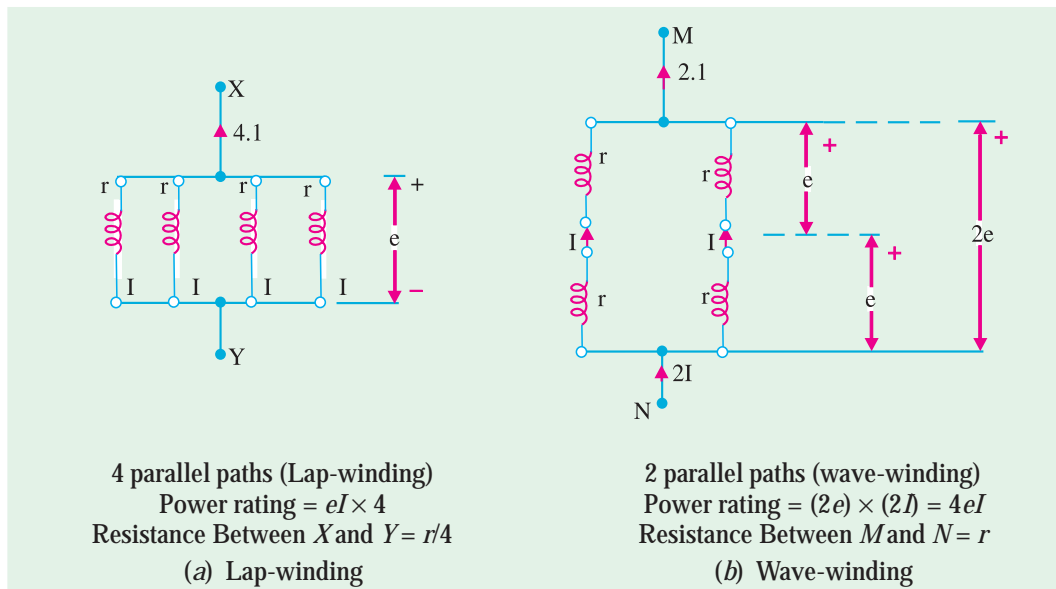

Fig. 26.67. Resistances for different methods

### Tutorial Problem No. 26.2

1. A 4-pole, d.c. generator has a wave-wound armature with 792 conductors. The flux per pole is 0.0121 Wb. Determine the speed at which it should be run to generate 240 V on no-load. [751.3 r.p.m.]

2. A 20 kW compound generator works on full-load with a terminal voltage of 230 V. The armature, series and shunt field resistances are 0.1, 0.05 and 115  $\Omega$  respectively. Calculate the generated e.m.f. when the generator is connected short-shunt. [243.25 V] (Elect. Engg. Madras Univ. April, 1978)

3. A d.c. generator generates an e.m.f. of 520 V. It has 2,000 armature conductors, flux per pole of 0.013 Wb, speed of 1200 r.p.m. and the armature winding has four parallel paths. Find the number of poles. [4] (Elect. Technology, Aligarh Univ. 1978)

4. When driven at 1000 r.p.m. with a flux per pole of 0.02 Wb, a d.c. generator has an e.m.f. of 200 V. If the speed is increased to 1100 r.p.m. and at the same time the flux per pole is reduced to 0.019 Wb per pole, what is then the induced e.m.f. ? [209 V]

5. Calculate the flux per pole required on full-load for a 50 kW, 400 V, 8-pole, 600 r.p.m. d.c. shunt generator with 256 conductors arranged in a lap-connected winding. The armature winding resistance is  $0.1 \Omega$ , the shunt field resistance is  $200 \Omega$  and there is a brush contact voltage drop of 1 V at each brush on full-load. **[0.162 Wb]**

6. Calculate the flux in a 4-pole dynamo with 722 armature conductors generating 500 V when running at 1000 r.p.m. when the armature is (a) lap connected (b) wave connected.

**[(a) 41.56 mWb (b) 20.78 mWb] (City & Guilds, London)**

7. A 4-pole machine running at 1500 r.p.m. has an armature with 90 slots and 6 conductors per slot. The flux per pole is 10 mWb. Determine the terminal e.m.f. as d.c. Generator if the coils are lap-connected. If the current per conductor is 100 A, determine the electrical power.

**[810 V, 324 kW] (London Univ.)**

8. An 8-pole lap-wound d.c. generator has 120 slots having 4 conductors per slot. If each conductor can carry 250 A and if flux/pole is 0.05 Wb, calculate the speed of the generator for giving 240 V on open circuit. If the voltage drops to 220 V on full load, find the rated output of the machine.

**[600 V, 440 kW]**

9. A 110-V shunt generator has a full-load current of 100 A, shunt field resistance of  $55 \Omega$  and constant losses of 500 W. If F.L. efficiency is 88%, find armature resistance. Assuming voltage to be constant at 110 V, calculate the efficiency at half F.L. And at 50% overload. Find the load current.

**[0.078  $\Omega$  ; 85.8% ; 96.2 A]**

10. A short-shunt compound d.c. Generator supplies a current of 100 A at a voltage of 220 V. If the resistance of the shunt field is  $50 \Omega$ , of the series field  $0.025 \Omega$ , of the armature  $0.05 \Omega$ , the total brush drop is 2 V and the iron and friction losses amount to 1 kW, find

(a) the generated e.m.f. (b) the copper losses (c) the output power of the prime-mover driving the generator and (d) the generator efficiency.

**[(a) 229.7 V (b) 1.995 kW (c) 24.99 kW (d) 88%]**

11. A 20 kW, 440-V, short-shunt, compound d.c. generator has a full-load efficiency of 87%. If the resistance of the armature and interpoles is  $0.4 \Omega$  and that of the series and shunt fields  $0.25 \Omega$  and  $240 \Omega$  respectively, calculate the combined bearing friction, windage and core-loss of the machine.

**[725 W]**

12. A long-shunt, compound generator delivers a load current of 50 A at 500 V and the resistances of armature, series field and shunt field are 0.05 ohm and 250 ohm respectively. Calculate the generated electromotive force and the armature current. Allow 1.0 V per brush for contact drop.

**[506.2 V ; 52 A] (Elect. Engg. Banaras Hindu Univ. 1977)**

13. In a 110-V compound generator, the resistances of the armature, shunt and the series windings are  $0.06 \Omega$ ,  $25 \Omega$  and  $0.04 \Omega$  respectively. The load consists of 200 lamps each rated at 55 W, 110 V.

Find the total electromotive force and armature current when the machine is connected (i) long shunt (ii) short shunt. Ignore armature reaction and brush drop.

**[(a) 1200.4, 104.4 A (b) 120.3 V, 104.6 A] (Electrical Machines-I, Bombay Univ. 1979)**

14. Armature of a 2-pole, 200-V generator has 400 conductors and runs at 300 r.p.m. Calculate the useful flux per pole. If the number of turns in each field coil is 1200, what is the average value of e.m.f. induced in each coil on breaking the field if the flux dies away completely in 0.1 sec ?

**(JNTU, Hyderabad, 2000)**

**Hint:** Calculate the flux per pole generating 200 V at 300 rpm. Calculate the e.m.f. induced in 1200-turn field coil due to this flux reducing to zero in 0.1 sec, from the rate of change of flux-linkage.

**[\(\phi\) = 0.1 Wb, e = 1200 V]**

**15.** A 1500 kW, 550-V, 16 pole generator runs at 150 rev. per min. What must be the useful flux if there are 2500 conductors lap-connected and the full-load copper losses are 25 kW? Calculate the area of the pole shoe if the gap density has a uniform value of  $0.9 \text{ wb/m}^2$  and find the no-load terminal voltage, neglecting armature reaction and change in speed.

(Rajiv Gandhi Techn. Univ., Bhopal, 2000) [0.09944 m<sup>2</sup>, 559.17 V]

### OBJECTIVE TESTS – 26

- The basic requirement of a d.c. armature winding is that it must be
  - a closed one
  - a lap winding
  - a wave winding
  - either (b) or (c)
- A wave winding must go at least ..... around the armature before it closes back where it started.
  - once
  - twice
  - thrice
  - four times
- The d.c. armature winding in which coil sides are a pole pitch apart is called ..... winding.
  - multiplex
  - fractional-pitch
  - full-pitch
  - pole-pitch
- For making coil span equal to a pole pitch in the armature winding of a d.c. generator, the back pitch of the winding must equal the number of
  - commutator bars per pole
  - winding elements
  - armature conductors per path
  - armature parallel paths.
- The primary reason for making the coil span of a d.c. armature winding equal to a pole pitch is to
  - obtain a coil span of  $180^\circ$  (electrical)
  - ensure the addition of e.m.fs. of consecutive turns
  - distribute the winding uniformly under different poles
  - obtain a full-pitch winding.
- In a 4-pole, 35 slot d.c. armature, 180 electrical-degree coil span will be obtained when coils occupy ..... slots.
  - 1 and 10
  - 1 and 9
  - 2 and 11
  - 3 and 12
- The armature of a d.c. generator has a 2-layer lap-winding housed in 72 slots with six conductors/slot. What is the minimum number of commutator bars required for the armature?
  - 72
  - 432
  - 216
  - 36
- The sole purpose of a commutator in a d.c. Generator is to
  - increase output voltage
  - reduce sparking at brushes
  - provide smoother output
  - convert the induced a.c. into d.c.
- For a 4-pole, 2-layer, d.c., lap-winding with 20 slots and one conductor per layer, the number of commutator bars is
  - 80
  - 20
  - 40
  - 160
- A 4-pole, 12-slot lap-wound d.c. armature has two coil-sides/slot. Assuming single turn coils and progressive winding, the back pitch would be
  - 5
  - 7
  - 3
  - 6
- If in the case of a certain d.c. armature, the number of commutator segments is found either one less or more than the number of slots, the armature must be having a simplex ..... winding.
  - wave
  - lap
  - frog leg
  - multielement
- Lap winding is suitable for ..... current, ..... voltage d.c. generators.
  - high, low
  - low, high
  - low, low
  - high, high

13. The series field of a short-shunt d.c. generator is excited by ..... currents.  
(a) shunt  
(b) armature  
(c) load  
(d) external
14. In a d.c. generator, the generated e.m.f. is directly proportional to the  
(a) field current  
(b) pole flux  
(c) number of armature parallel paths  
(d) number of dummy coils
15. In a 12-pole triplex lap-wound d.c. armature, each conductor can carry a current of 100 A. The rated current of this armature is ..... ampere.  
(a) 600  
(b) 1200  
(c) 2400  
(d) 3600
16. The commercial efficiency of a shunt generator is maximum when its variable loss equals ..... loss.  
(a) constant  
(b) stray  
(c) iron  
(d) friction and windage
17. In small d.c. machines, armature slots are sometimes not made axial but are skewed. Though skewing makes winding a little more difficult, yet it results in  
(a) quieter operation  
(b) slight decrease in losses  
(c) saving of copper  
(d) both (a) and (b)
18. The critical resistance of the d.c. generator is the resistance of  
(a) armature  
(b) field  
(c) load  
(d) brushes (Grad. I.E.T.E Dec. 1985)

## ANSWERS

## ARMATURE REACTION AND COMMUTATION

↑ Armature reaction is the change in the neutral plane and the reaction of the magnetic field

### 27.1 Armature Reaction

By armature reaction is meant the effect of magnetic field set up by armature current on the distribution of flux under main poles of a generator. The armature magnetic field has two effects :

- (i) *It demagnetises or weakens the main flux* and
- (ii) *It cross-magnetises or distorts it.*

The first effect leads to reduced generated voltage and the second to the sparking at the brushes.

These effects are well illustrated in Fig. 27.1 which shows the flux distribution of a bipolar generator when there is no current in the armature conductors. For convenience, only two poles have been considered, though the following remarks apply to multipolar fields as well. Moreover, the brushes are shown touching the armature conductors directly, although in practice, they touch commutator segments, It is seen that

- (a) the flux is distributed symmetrically with respect to the polar axis, which is the line joining the centres of *NS* poles.
- (b) The magnetic neutral axis or plane (*M.N.A.*) coincides with the geometrical neutral axis or plane (*G.N.A.*)

Magnetic neutral axis may be defined as the axis along which no e.m.f. is produced in the armature conductors because they then move parallel to the lines of flux.

Or *M.N.A.* is the axis which is perpendicular to the flux passing through the armature.

As hinted in Art. 27.2, brushes are always placed along *M.N.A.* Hence, *M.N.A.* is also called 'axis of commutation' because reversal of current in armature conductors takes place across this axis.

Fig. 27.2

As shown in Fig. 27.2, the m.m.fs. of the armature conductors combine to send flux downwards through the armature. The direction of the lines of force can be found by applying cork-screw rule. The armature m.m.f. (depending on the strength of the armature current) is shown separately both in magnitude and direction by the vector  $OF_A$  which is parallel to the brush axis.

So far, we considered the main m.m.f. and armature m.m.f. separately as if they existed independently, which is not the case in practice. Under actual load conditions, the two exist simultaneously in

Fig. 27.1

In Fig. 27.1 is shown vector  $OF_m$  which represents, both in magnitude and direction, the m.m.f. producing the main flux and also *M.N.A.* which is perpendicular to  $OF_m$ .

In Fig. 27.2 is shown the field (or flux) set up by the armature conductors *alone* when carrying current, the field coils being unexcited. The direction of the armature current is the same as it would actually be when the generator is loaded. It may even be found by applying Fleming's Right-hand Rule. The current direction is downwards in conductors under *N*-pole and upwards in those under *S*-pole. The downward flow is represented by crosses and upward flow by dots.

the generator as shown in Fig. 27.3.

Fig. 27.3

Fig. 27.4

It is seen that the flux through the armature is no longer uniform and symmetrical about the pole axis, rather it has been distorted. The flux is seen to be crowded at the trailing pole tips but weakened or thinned out at the leading pole tips (the pole tip which is first met during rotation by armature conductors is known as the leading pole tip and the other as trailing pole tip). The strengthening and weakening of flux is separately shown for a four-pole machine in Fig. 27.4. As seen, air-gap flux density under one pole half is greater than that under the other pole half.

If Fig. 27.3 is shown the resultant m.m.f.  $OF$  which is found by vectorially combining  $OF_m$  and  $OF_A$ .

The new position of  $M.N.A.$ , which is always perpendicular to the resultant m.m.f. vector  $OF$ , is also shown in the figure. With the shift of  $M.N.A.$ , say through an angle  $\theta$ , brushes are also shifted so as to lie along the new position of  $M.N.A.$  Due to this brush shift (or forward lead), the armature conductors and hence armature current is redistributed. Some armature conductors which were earlier

Armature reaction

under the influence of *N*-pole come under the influence of *S*-pole and *vice-versa*. This regrouping is shown in Fig. 27.5, which also shows the flux due to armature conductors. Incidentally, brush position shifts in the *same* direction as the direction of armature rotation.

All conductors to the left of new position of *M.N.A.* but between the two brushes, carry current downwards and those to the right carry current upwards. The armature m.m.f. is found to lie in the direction of the new position of *M.N.A.* (or brush axis). The armature m.m.f. is now represented by the vector  $OF_A$  which is not vertical (as in Fig 27.2) but is inclined by an angle  $\theta$  to the left. It can now be resolved into two rectangular components,  $OF_d$  parallel to polar axis and  $OF_C$  perpendicular to this axis. We find that

(i) component  $OF_C$  is at right angles to the vector  $OF_m$  (of Fig. 27.1) representing the main m.m.f. It produces distortion in the main field and is hence called the cross-magnetising or distorting component of the armature reaction.

(ii) The component  $OF_d$  is in direct opposition of  $OF_m$  which represents the main m.m.f. It exerts a demagnetising influence on the main pole flux. Hence, it is called the demagnetising or weakening component of the armature reaction.

It should be noted that both distorting and demagnetising effects will increase with increase in the armature current.

### 27.2. Demagnetising and Cross-magnetising Conductors

The exact conductors which produce these distorting and demagnetising effects are shown in Fig. 27.6 where the brush axis has been given a forward lead of  $\theta$  so as to lie along the new position of *M.N.A.* All conductors lying within angles  $AOC = BOD = 2\theta$  at the top and bottom of the armature, are carrying current in such a direction as to send the flux *through* the armature from right to left. This fact may be checked by applying crockscrew rule. It is these conductors which act in direct opposition to the main field and are hence called the demagnetising armature conductors.

Fig. 27.5

Fig. 27.6

Fig. 27.7

Now consider the remaining armature conductors lying between angles  $AOD$  and  $COB$ . As shown in Fig. 27.7, these conductors carry current in such a direction as to produce a combined flux pointing vertically downwards *i.e.* at right angles to the main flux. This results in distortion of the main field. Hence, these conductors are known as cross-magnetising conductors and constitute distorting ampere-conductors.

### 27.3. Demagnetising AT per Pole

Since armature demagnetising ampere-turns are neutralized by adding extra ampere-turns to the main field winding, it is essential to calculate their number. But before proceeding further, it should be remembered that the number of turns is equal to half the number of conductors because two conductors-constitute one turn.

$$\begin{aligned} \text{Let } Z &= \text{total number of armature conductors} \\ I &= \text{current in each armature conductor} \\ &= I_d/2 \quad \dots \text{ for simplex wave winding} \\ &= I_d/P \quad \dots \text{ for simplex lap winding} \\ \theta_m &= \text{forward lead in mechanical or geometrical or angular degrees.} \end{aligned}$$

$$\text{Total number of armature conductors in angles } AOC \text{ and } BOD \text{ is } \frac{4\theta_m}{360} \times Z$$

As two conductors constitute one turn,

$$\therefore \text{Total number of turns in these angles} = \frac{2\theta_m}{360} \times ZI$$

$$\therefore \text{Demagnetising amp-turns per pair of poles} = \frac{2\theta_m}{360} \times ZI$$

$$\therefore \text{Demagnetising amp - turns/pole} = \frac{\theta_m}{360} \times ZI \quad \therefore AT_d \text{ per pole} = ZI \times \frac{\theta_m}{360}$$

### 27.4. Cross-magnetising AT per pole

The conductors lying between angles  $AOD$  and  $BOC$  constitute what are known as distorting or cross-magnetising conductors. Their number is found as under :

$$\text{Total armature-conductors/pole both cross and demagnetising} = Z/P$$

$$\text{Demagnetising conductors/pole} = Z \cdot \frac{2\theta_m}{360} \quad (\text{found above})$$

$$\therefore \text{Cross-magnetising conductors/pole} = \frac{Z}{P} - Z \times \frac{2\theta_m}{360} = Z \left( \frac{1}{P} - \frac{2\theta_m}{360} \right)$$

$$\therefore \text{Cross-magnetising amp-conductors/pole} = ZI \left( \frac{1}{P} - \frac{2\theta_m}{360} \right)$$

$$\therefore \text{Cross-magnetising amp-turns/pole} = ZI \left( \frac{1}{2P} - \frac{\theta_m}{360} \right)$$

(Remembering that two conductors make one turn)

$$\therefore AT_c/\text{pole} = ZI \left( \frac{1}{2P} - \frac{\theta_m}{360} \right)$$

**Note. (i)** For neutralizing the demagnetising effect of armature-reaction, an extra number of turns may be put on each pole.

$$\text{No. of extra turns/pole} = \frac{AT_d}{I_{sh}} \quad \text{—for shunt generator}$$

$$= \frac{AT_d}{I_a} \quad \text{—for series generator}$$

If the leakage coefficient  $\lambda$  is given, then multiply each of the above expressions by it.

(ii) If lead angle is given in electrical degrees, it should be converted into mechanical degrees by the following relation.

$$\theta \text{ (mechanical)} = \frac{\theta \text{ (electrical)}}{\text{pair of poles}} \text{ or } \theta_m = \frac{\theta_e}{P/2} = \frac{2\theta_e}{P}$$

### 27.5. Compensating Windings

These are used for large direct current machines which are subjected to large fluctuations in load *i.e.* rolling mill motors and turbo-generators etc. Their function is to neutralize the cross magnetizing effect of armature reaction. In the absence of compensating windings, the flux will be suddenly shifting backward and forward with every change in load. This shifting of flux will induce *statically* induced e.m.f. in the armature coils. The magnitude of this e.m.f. will depend upon the rapidity of changes in load and the amount of change. It may be so high as to strike an arc between the consecutive commutator segments across the top of the mica sheets separating them. This may further develop into a flash-over around the whole commutator thereby short-circuiting the whole armature.

Fig. 27.8

These windings are embedded in slots in the pole shoes and are connected in series with armature in such a way that the current in them flows in opposite direction to that flowing in armature conductors directly below the pole shoes. An elementary scheme of compensating winding is shown in Fig. 27.8.

It should be carefully noted that compensating winding must provide sufficient m.m.f so as to counterbalance the armature m.m.f. Let

$$\begin{aligned} Z_c &= \text{No. of compensating conductors/pole face} \\ Z_a &= \text{No. of active armature conductors/pole,} \\ I_a &= \text{Total armature current} \\ I_a/A &= \text{current/armature conductor} \\ \therefore Z_c I_a &= Z_a (I_a/A) \text{ or } Z_c = Z_a/A \end{aligned}$$

Owing to their cost and the room taken up by them, the compensating windings are used in the case of large machines which are subject to violent fluctuations in load and also for generators which have to deliver their full-load output at considerable low induced voltage as in the Ward-Leonard set.

### 27.6. No. of Compensating Windings

$$\text{No. of armature conductors/pole} = \frac{Z}{P} \quad \text{No. of armature turns/pole} = \frac{Z}{2P}$$

∴ No. of armature-turns immediately under one pole

$$= \frac{Z}{2P} \times \frac{\text{Pole arc}}{\text{Pole pitch}} = 0.7 \times \frac{Z}{2P} \text{ (approx.)}$$

∴ No. of armature amp-turns/pole for compensating winding

$$= 0.7 \times \frac{Z}{2P} = 0.7 \times \text{armature amp-turns/pole}$$

**Example 27.1.** A 4-pole generator has a wave-wound armature with 722 conductors, and it delivers 100 A on full load. If the brush lead is 8°, calculate the armature demagnetising and cross-magnetising ampere turns per pole.

(Advanced Elect. Machines AMIE Sec. B 1991)

**Solution.**  $I = I_a/2 = 100/2 = 50\text{A}$ ;  $Z = 722$ ;  $\theta_m = 8^\circ$

$$\text{AT}_d/\text{pole} = ZI \cdot \frac{\theta_m}{360} = 722 \times 50 \times \frac{8}{360} = 802$$

$$\begin{aligned} \text{AT}_c/\text{pole} &= ZI \cdot \left( \frac{1}{2P} - \frac{\theta_m}{360} \right) \\ &= 722 \times 50 \left( \frac{1}{2 \times 4} - \frac{8}{360} \right) = 37/8 \end{aligned}$$

**Example 27.2** An 8-pole generator has an output of 200 A at 500 V, the lap-connected armature has 1280 conductors, 160 commutator segments. If the brushes are advanced 4-segments from the no-load neutral axis, estimate the armature demagnetizing and cross-magnetizing ampere-turns per pole.

(Electrical Machines-I, South Gujarat Univ. 1986)

**Solution.**  $I = 200/8 = 25\text{ A}$ ,  $Z = 1280$ ,  $\theta_m = 4 \times 360/160 = 9^\circ$ ;  $P = 8$

$$\text{AT}_d/\text{pole} = ZI\theta_m/360 = 1280 \times 25 \times 9/360 = \mathbf{800}$$

$$\text{AT}_c/\text{pole} = ZI \left( \frac{1}{2P} - \frac{\theta_m}{360} \right) = 1280 \times 25 \left( \frac{1}{2 \times 8} - \frac{9}{360} \right) = \mathbf{1200}$$

**Note.** No. of coils = 160, No. of conductors = 1280. Hence, each coil side contains 1280/160 = 8 conductors.

**Example 27.3(a).** A 4-pole wave-wound motor armature has 880 conductors and delivers 120 A. The brushes have been displaced through 3 angular degrees from the geometrical axis. Calculate (a) demagnetising amp-turns/pole (b) cross- magnetising amp-turns/pole (c) the additional field current for neutralizing the demagnetisation of the field winding has 1100 turns/pole.

**Solution.**  $Z = 880$ ;  $I = 120/2 = 60\text{ A}$ ;  $\theta = 3^\circ$  angular

$$(a) \therefore \text{AT}_d = 880 \times 60 \times \frac{3}{360} = \mathbf{440\text{ AT}}$$

$$(b) \therefore \text{AT}_c = 880 \times 60 \left( \frac{1}{8} - \frac{3}{360} \right) = 880 \times \frac{7}{60} \times 60 = \mathbf{6,160}$$

or Total AT/pole = 440 × 60/4 = 6600

Hence,  $\text{AT}_c/\text{pole} = \text{Total AT/pole} - \text{AT}_d/\text{pole} = 6600 - 440 = 6160$

(c) Additional field current = 440/1100 = **0.4 A.**

**Example 27.3(b).** A 4-pole lap-wound Generator having 480 armature conductors supplies a current of 150 Amps. If the brushes are given an actual lead of 10°, calculate the demagnetizing and cross-magnetizing amp-turns per pole.

(Bharathiar Univ. April 1998)

**Solution.** 10° mechanical (or actual) shift = 20° electrical shift for a 4-pole machine.

Armature current = 150 amp

For 4-pole lap-wound armature, number of parallel paths = 4. Hence, conductor-current =  $150/4 = 37.5$  amps.

$$\text{Total armature amp-turns/pole} = \frac{1}{2} \times \frac{(480 \times 37.5)}{14} = 2250$$

$$\text{Cross - magnetizing amp turns/pole} = 2250 \times \left(1 - \frac{2 \times 20^\circ}{180^\circ}\right) = 1750$$

$$\text{Demagnetizing amp turns/pole} = 2250 \times (2 \times 20^\circ/180^\circ) = 500$$

**Example 27.4.** A 4-pole generator supplies a current of 143 A. It has 492 armature conductors (a) wave-wound (b) lap-wound. When delivering full load, the brushes are given an actual lead of  $10^\circ$ . Calculate the demagnetising amp-turns/pole. This field winding is shunt connected and takes 10 A. Find the number of extra shunt field turns necessary to neutralize this demagnetisation.

(Elect. Machines, Nagpur Univ. 1993 & JNTU Hyderabad, 2000 & RGPU, Bhopal, 2000)

**Solution.**  $Z = 492$  ;  $\theta_m = 10^\circ$  ;  $AT_d/\text{pole} = Z I \times \frac{\theta}{360}$   
 $I_a = 143 + 10 = 153 \text{ A}$  ;  $I = 153/2$  ... when wave-wound  
 $= 153/4$  ... when lap-wound

(a)  $\therefore AT_d/\text{pole} = 492 \times \frac{153}{2} \times \frac{10}{360} = 1046 \text{ AT}$

Extra shunt field turns =  $1046/10 = 105$  (approx.)

(b)  $AT_d/\text{pole} = 492 \times \frac{153}{2} \times \frac{10}{360} = 523$

Extra shunt field turns =  $523/10 = 52$  (approx.)

**Example 27.5.** A 4-pole, 50-kW, 250-V wave-wound shunt generator has 400 armature conductors. Brushes are given a lead of 4 commutator segments. Calculate the demagnetisation amp-turns/pole if shunt field resistance is  $50 \Omega$ . Also, calculate extra shunt field turns/pole to neutralize the demagnetisation.

**Solution.** Load current supplied =  $50,000/250 = 200 \text{ A}$   
 $I_{sh} = 250/50 = 5 \text{ A}$   $\therefore I_a = 200 + 5 = 205 \text{ A}$

Current in each conductor  $I = 205/2 \text{ A}$

No. of commutator segments =  $N/A$  where  $A = 2$  ... for wave-winding

$\therefore$  No. of segments =  $\frac{400}{2} = 200$  ;  $\theta = \frac{4}{200} \times 360 = \frac{36}{5}$  degrees

$\therefore AT_d/\text{pole} = 400 \times \frac{205}{2} \times \frac{36}{5 \times 360} = 820 \text{ AT}$

Extra shunt turns/poles =  $\frac{AT_d}{I_{sh}} = \frac{820}{5} = 164$

**Example 27.6.** Determine per pole the number (i) of cross-magnetising ampere-turns (ii) of back ampere-turns and (iii) of series turns to balance the back ampere-turns in the case of a d.c. generator having the following data.

500 conductors, total current 200 A, 6 poles, 2-circuit wave winding, angle of lead =  $10^\circ$ , leakage coefficient = 1.3 (Electrical Machines-I, Bombay University, 1986)

**Solution.** Current/path,  $I = 200/2 = 100 \text{ A}$ ,  $\theta = 10^\circ$  (mech),  $Z = 500$

(a)  $AT_c/\text{pole} = ZI \left( \frac{1}{2P} - \frac{\theta_m}{360} \right) = 500 \times 100 \left( \frac{1}{2 \times 6} - \frac{10}{360} \right) = 2,778$

(b)  $AT_d/\text{pole} = 500 \times 100 \times 10/360 = 1390$

(c) Series turns required to balance the demagnetising ampere-turns are

$$= \lambda \times \frac{AT_d}{I_a} = 1.3 \times \frac{1390}{200} = 9$$

**Example 27.7.** A 22.38 kW, 440-V, 4-pole wave-wound d.c. shunt motor has 840 armature conductors and 140 commutator segments. Its full-load efficiency is 88% and the shunt field current is 1.8 A. If brushes are shifted backward through 1.5 segments from the geometrical neutral axis, find the demagnetising and distorting amp-turns/pole. (Elect. Engg. Punjab Univ. 1991)

**Solution.** The shunt motor is shown diagrammatically in Fig. 27.9.

$$\begin{aligned} \text{Motor output} &= 22,380 \text{ W} ; \eta = 0.88 \\ \therefore \text{Motor input} &= 22,380/0.88 \text{ W} \\ \text{Motor input current} &= \frac{22,380}{0.88 \times 440} = 57.8 \text{ A} \\ I_{sh} = 1.8 \text{ A} ; \quad I_a &= 57.8 - 1.8 = 56 \text{ A} \\ \text{Current in each conductor} &= 56/2 = 28 \text{ A} \\ \theta &= 1.5 \times 360/140 \\ &= 27/7 \text{ degrees} \end{aligned}$$

Fig. 27.9

$$\therefore AT_d/\text{pole} = 840 \times 28 \times \frac{27}{7 \times 360} = 252$$

$$AT_c/\text{pole} = ZI \left( \frac{1}{2P} - \frac{\theta_m}{360} \right) = 840 \times 28 \left( \frac{1}{8} - \frac{27}{7 \times 360} \right) = 2,688$$

**Example 27.8.** A 400-V, 1000-A, lap-wound d.c. machine has 10 poles and 860 armature conductors. Calculate the number of conductors in the pole face to give full compensation if the pole face covers 70 % of pole span.

**Solution.** AT/pole for compensating winding

$$= \text{armature amp-turn/pole} \times \frac{\text{pole arc}}{\text{pole pitch}} = 0.7 \times \frac{ZI}{2P}$$

Here  $I = \text{current in each armature conductor} = 1,000/10 = 100 \text{ A}$   
 $Z = 860 ; P = 10$

$$\therefore AT/\text{pole for compensating winding} = 0.7 \times 860 \times 100/2 \times 10 = 3,010$$

### Tutorial Problem No. 27.1

1. Calculate the demagnetising amp-turns of a 4-pole, lap-wound generator with 720 turns, giving 50 A, if the brush lead is 10° (mechanical). (250 AT/pole)
2. A 250-V, 25-kW, 4-pole d.c. generator has 328 wave-connected armature conductors. When the machine is delivering full load, the brushes are given a lead of 7.2 electrical degrees. Calculate the cross-magnetising amp-turns/pole. (1886, 164)
3. An 8-pole lap-connected d.c. shunt generator delivers an output of 240 A at 500 V. The armature has 1408 conductors and 160 commutator segments. If the brushes are given a lead of 4 segments from the no-load neutral axis, estimate the demagnetising and cross-magnetising AT/pole. (1056, 1584) (Electrical Engineering, Bombay Univ. 1978)
4. A 500-V, wave-wound, 750 r.p.m. shunt generator supplies a load of 195 A. The armature has 720 conductors and shunt field resistance is 100 Ω. Find the demagnetising amp-turns/pole if brushes are advanced through 3 commutator segments at this load. Also, calculate the extra shunt field turns required to neutralize this demagnetisation. (600, 4800, 120)

5. A 4-pole, wave-wound generator has 320 armature conductors and carries an armature current of 400 A. If the pole arc/pole pitch ratio is 0.68, calculate the AT/pole for a compensating winding to give uniform flux density in the air gap. (5440)

6. A 500-kW, 500-V, 10 pole d.c. generator has a lap-wound armature with 800 conductors. Calculate the number of pole-face conductors in each pole of a compensating winding if the pole face covers 75 percent of the pitch.

(6 conductors/pole)

7. Three shunt generators, each having an armature resistance of 0.1 ohm are connected across a common bus feeding a two ohms load. Their generated voltages are 127 V, 120 V, and 119 V. Neglecting field currents, calculate the bus voltage and modes of operations of the three machines. (JNTU, Hyderabad, 200)

**Hint :** Solve the circuit from the data given. Since the voltages differ considerably, first machine with 127 V as the generated voltage with supply the largest current.

( $I_1 = 70$  amp, Generating mode,  $I_2 = 0$ ,  
Floating (= neither generating nor motoring).  
 $I_3 = -10$  amp, motoring mode  $I_L = 60$  amp.)

### 27.7. Commutation

It was shown in Art 26.2 that currents induced in armature conductors of a d.c. generator are alternating. To make their flow unidirectional in the external circuit, we need a commutator. Moreover, these currents flow in one direction when armature conductors are under  $N$ -pole and in the opposite direction when they are under  $S$ -pole. As conductors pass out of the influence of a  $N$ -pole and enter that of  $S$ -pole, the current in them is reversed. This reversal of current takes place along magnetic neutral axis or brush axis *i.e.* when the brush spans and hence short-circuits that particular coil undergoing reversal of current through it. This process by which current in the short-circuited coil is reversed while it crosses the  $M.N.A.$  is called commutation. The brief period during which coil remains short-circuited is known as commutation period  $T_c$ .

If the current reversal *i.e.* the change from  $+I$  to zero and then to  $-I$  is completed by the end of short circuit or commutation period, then the commutation is ideal. If current reversal is not complete by that time, then sparking is produced between the brush and the commutator which results in progressive damage to both.

Let us discuss the process of commutation or current reversal in more detail with the help of Fig. 27.10 where ring winding has been used for simplicity. The brush width is equal to the width of one commutator segment and one mica insulation. In Fig. 27.10 (a) coil  $B$  is about to be short circuited because brush is about to come in touch with commutator segment 'a'. It is assumed that each coil carries 20 A, so that brush current is 40 A. It is so because every coil meeting at the brush supplies half the brush current lap wound or wave wound. Prior to the beginning of short circuit, coil  $B$  belongs to the group of coils lying to the left of the brush and carries 20 A from left to right. In Fig. 27.10 (b) coil  $B$  has entered its period of short-circuit and is approximately at one-third of this period. The current through coil  $B$  has reduced down from 20 A to 10 A because the other 10 A flows *via* segment 'a'. As area of contact of the brush is more with segment 'b' than with segment 'a', it receives 30 A from the former, the total again being 40 A.

Commutation

Fig. 27.10 (c) shows the coil *B* in the middle of its short-circuit period. The current through it has decreased to zero. The two currents of value 20 A each, pass to the brush directly from coil *A* and *C* as shown. The brush contact areas with the two segments 'b' and 'a' are equal.

Fig. 27.10

Fig. 27.11

In Fig. 27.10 (d), coil *B* has become part of the group of coils lying to the right of the brush. It is seen that brush contact area with segment 'b' is decreasing rapidly whereas that with segment 'a' is increasing. Coil *B* now carries 10 A in the reverse direction which combines with 20 A supplied by coil *A* to make up 30 A that passes from segment 'a' to the brush. The other 10 A is supplied by coil *C* and passes from segment 'b' to the brush, again giving a total of 40 A at the brush.

Fig. 27.10 (e) depicts the moment when coil *B* is almost at the end of commutation or short-circuit period. For ideal commutation, current through it should have reversed by now but, as shown, it is carrying 15 A only (instead of 20 A). The difference of current between coils *C* and *B* i.e.  $20.15 = 5$  A in this case, jumps directly from segment *b* to the brush through air thus producing spark.

If the changes of current through coil *B* are plotted on a time base (as in Fig. 27.11) it will be represented by a horizontal line *AB* i.e. a constant current of 20 A up to the time of beginning of commutation. From the finish of commutation, the current will be represented by another horizontal line *CD*. Now, again the current value is  $FC = 20$  A, although in the reversed direction. The way in which current changes from its positive value of 20 A (= *BE*) to zero and then to its negative value of 20 A (= *CF*) depends on the conditions under which the coil *B* undergoes commutation. If the current varies at a uniform rate i.e. if *BC* is a straight line, then it is referred to as linear commutation. However, due to the production of self-induced e.m.f. in the coil (discussed below) the variations follow the dotted curve. It is seen that, in that case, current in coil *B* has reached only a value of *KF* = 15 A in the reversed direction, hence the difference of 5 A (20 A – 15 A) passes as a spark.

So, we conclude that sparking at the brushes, which results in poor commutation is due to the inability of the current in the short-circuited coil to reverse completely by the end of short-circuit period (which is usually of the order of 1/500 second).

At this stage, the reader might ask for the reasons which make this current reversal impossible in the specified period *i.e.* what factors stand in the way of our achieving ideal commutation. The main cause which retards or delays this quick reversal is the production of self-induced e.m.f. in the coil undergoing commutation. It may be pointed out that the coil possesses appreciable amount of self inductance because it lies embedded in the armature which is built up of a material of high magnetic permeability. This self-induced e.m.f. is known as **reactance voltage** whose value is found as given below. This voltage, even though of a small magnitude, produces a large current through the coil whose resistance is very low due to short circuit. It should be noted that if the brushes are set so that the coils undergoing short-circuit are in the magnetic neutral plane, where they are cutting no flux and hence have no e.m.f. induced in them due to armature rotation, there will still be the e.m.f. of self-induction which causes severe sparking at the brushes.

### 27.8. Value of Reactance Voltage

Reactance voltage = coefficient of self-inductance  $\times$  rate of change of current.

It should be remembered that the time of short-circuit or commutation is the time required by the commutator to move a distance equal to the circumferential thickness of the brush minus the thickness of one insulating plate of strip of mica.

$$\begin{aligned} \text{Let} \quad & W_b = \text{brush width in cm; } W_m = \text{width of mica insulation in cm} \\ & v = \text{peripheral velocity of commutator segments in cm/second} \\ \text{Then} \quad & T_c = \text{time of commutation or short-circuit} = \frac{W_b - W_m}{v} \text{ second} \end{aligned}$$

**Note.** If brush width etc. are given in terms of commutator segments, then commutator velocity should also be converted in terms of commutator segments per second.

If  $I$  is the current through a conductor, then total change during commutation =  $I - (-I) = 2I$ .

$$\begin{aligned} \therefore \text{ Self-induced or reactance voltage} \\ &= L \times \frac{2I}{T_c} \quad \text{-- if commutation is linear} \\ &= 1.11 L \times \frac{2I}{T_c} \quad \text{-- if commutation is sinusoidal} \end{aligned}$$

As said earlier, the reactance e.m.f. hinders the reversal of current. This means that there would be sparking at the brushes due to the failure of the current in short-circuited coil to reach its full value in the reversed direction by the end of short-circuit. This sparking will not only damage the brush and the commutator but this being a cumulative process, it may worsen and eventually lead to the short-circuit of the whole machine by the formation of an arc round the commutator from brush to brush.

**Example 27.9.** The armature of a certain dynamo runs at 800 r.p.m. The commutator consists of 123 segments and the thickness of each brush is such that the brush spans three segments. Find the time during which the coil of an armature remains short-circuited.

**Solution.** As  $W_m$  is not given, it is considered negligible.

$$W_b = 3 \text{ segments and } v = (800/60) \times 123 \text{ segments/second}$$

$$\therefore \text{ commutation time} = \frac{3 \times 60}{800 \times 123} = 0.00183 \text{ second} = \mathbf{1.83 \text{ millisecond}}$$

**Example 27.10.** A 4-pole, wave-wound, d.c. machine running at 1500 r.p.m. has a commutator of 30 cm diameter. If armature current is 150 A, thickness of brush 1.25 cm and the self-inductance of each armature coil is 0.07 mH, calculate the average e.m.f. induced in each coil during commutation. Assume linear commutation.

**Solution.** Formula :  $E = L \frac{2I}{T_c}$

Here  $L = 0.07 \times 10^{-3}$  H,  $I = 150/2 = 75$  A (It is wave-wound)

$W_b = 1.25$  cm,  $W_m = 0$  ...considered negligible

$v = \pi \times 30 \times (1500/60) = 2356$  cm/s ;  $T_c = W_b/v = 1.25/2356 = 5.3 \times 10^{-4}$  second

$E = L \times 2I/T_c = 0.07 \times 10^{-3} \times 2 \times 75/5.3 \times 10^{-4} = 19.8$  V

**Example 27.11.** Calculate the reactance voltage for a machine having the following particulars. Number of commutator segments = 55, Revolutions per minute = 900, Brush width in commutator segments = 1.74, Coefficient of self-induction =  $153 \times 10^{-6}$  henry, Current per coil = 27 A.

(Advanced Elect. Machines. AMIE Sec. Winter 1991)

**Solution.** Current per coil,  $I = 27$  A ;  $L = 153 \times 10^{-6}$  H

$v = 55 \times (900/60) = 825$  segments/second;  $T_c = W_b/v = 1.74/825 = 2.11 \times 10^{-3}$  second

Assuming linear commutation,  $E = L \times 2I/T_c$

$\therefore E = 153 \times 10^{-6} \times 2 \times 27/2.11 \times 10^{-3} = 3.91$  V

**Example 27.12.** A 4-pole, lap-wound armature running at 1500 r.p.m. delivers a current of 150 A and has 64 commutator segments. The brush spans 1.2 segments and inductance of each armature coil is 0.05 mH. Calculate the value of reactance voltage assuming (i) linear commutation (ii) sinusoidal commutation. Neglect mica thickness.

**Solution.** Formula :  $E = L \cdot \frac{2I}{T_c}$  Now,  $L = 0.05 \times 10^{-3}$  H;  $W_b = 1.2$  segments

$v = \frac{1500}{60} \times 64 = 1600$  segments/second

$\therefore T_c = \frac{1.2}{1600} = 7.5 \times 10^{-4}$  second ;  $I = \frac{150}{4}$  A = 37.5 A

$\therefore \frac{2I}{T_c} = \frac{2 \times 37.5}{7.5 \times 10^{-4}} = 10^5$  A/s

For linear commutation,  $E = 0.05 \times 10^{-3} \times 10^5 = 5$  V

For sinusoidal commutation,  $E = 1.11 \times 5 = 5.55$  V

### 27.9. Methods of Improving Commutation

There are two practical ways of improving commutation *i.e.* of making current reversal in the short-circuited coil as sparkless as possible. These methods are known as (i) resistance commutation and (ii) e.m.f. commutation (which is done with the help of either brush lead or interpoles, usually the later).

#### 27.10. Resistance Commutation

This method of improving commutation consists of replacing low-resistance Cu brushes by comparatively high-resistance carbon brushes.

From Fig. 27.12, it is seen that when current  $I$  from coil 'C' reaches the commutator segment  $b$ , it has two parallel paths open to it. The first part is straight from bar 'b' to the brush and the other parallel path is *via* the short-circuited coil B to bar 'a' and then to the brush. If the Cu brushes (which have low contact resistance) are used, then there is no inducement for the current to follow the sec-

Fig. 27.12

ond longer path, it would preferably follow the first path. But when carbon brushes having high resistance are used, then current  $I$  coming from  $C$  will prefer to pass through the second path because (i) the resistance  $r_1$  of the first path will increase due to the diminishing area of contact of bar 'b' with the brush and because (ii) resistance  $r_2$  of second path will decrease due to rapidly increasing contact area of bar 'a' with the brush.

Hence, carbon brushes have, usually, replaced Cu brushes. However, it should be clearly understood that the main cause of sparking commutation is the self-induced e.m.f. (*i.e.* reactance voltage), so brushes alone do not give a sparkless commutation; though they do help in obtaining it.

The additional advantages of carbon brushes are that (i) they are to some degree self-lubricating and polish the commutator and (ii) should sparking occur, they would damage the commutator less than when Cu brushes are used.

But some of their minor disadvantages are : (i) Due to their high contact resistance (which is beneficial to sparkless commutation) a loss of approximately 2 volt is caused. Hence, they are not much suitable for small machines where this voltage forms an appreciable percentage loss. (ii) Owing to this large loss, the commutator has to be made some what larger than with Cu brushes in order to dissipate heat efficiently without greater rise of temperature. (iii) because of their lower current density (about 7-8 A/cm<sup>2</sup> as compared to 25-30 A/cm<sup>2</sup> for Cu brushes) they need larger brush holders.

### 27.11. E.M.F. Commutation

In this method, arrangement is made to neutralize the reactance voltage by producing a reversing e.m.f. in the short-circuited coil under commutation. This reversing e.m.f., as the name shows, is an e.m.f. in opposition to the reactance voltage and if its value is made equal to the latter, it will completely wipe it off, thereby producing quick reversal of current in the short-circuited coil which will result in sparkless commutation. The reversing e.m.f. may be produced in two ways : (i) either by giving the brushes a forward lead sufficient enough to bring the short-circuited coil under the influence of next pole of opposite polarity or (ii) by using interpoles.

The first method was used in the early machines but has now been abandoned due to many other difficulties it brings along with.

### 27.12. Interpoles of Compoles

These are small poles fixed to the yoke and spaced in between the main poles. They are wound with comparatively few heavy gauge Cu wire turns and are connected in series with the armature so that they carry full armature current. Their polarity, in the case of a generator, is the same as that of the main pole *ahead* in the direction of rotation (Fig. 25.13).

The function of interpoles is two-fold :

(i) As their polarity is the same as that of the main pole ahead, they induce an e.m.f. in the coil (under commutation) which helps the reversal of current. The e.m.f. induced by the compoles is known as *commutating or reversing e.m.f.* The commutating e.m.f. neutralizes the reactance e.m.f. thereby making commutation sparkless. With interpoles, sparkless commutation can be obtained up to 20 to 30% overload with fixed brush position. In fact, interpoles raise sparking limit of a machine to *almost* the same value as heating limit. Hence, for a given output, an interpole machine can be made smaller and, therefore, cheaper than a non-interpolar machine.

As interpoles carry armature current, their commutating e.m.f. is proportional to the armature current. **This ensures automatic neutralization of reactance voltage which is also due to armature current.** Connections for a shunt generator with interpoles are shown in Fig. 27.14.

(ii) Another function of the interpoles is to neutralize the cross-magnetising effect of armature reaction. Hence, brushes are not to be shifted from the original position. In Fig 27.15,  $OF$  as before, represents the m.m.f. due to main poles.  $OA$  represents the cross-magnetising m.m.f. due to armature.  $BC$  which represents m.m.f. due to interpoles, is obviously in opposition to  $OA$ , hence they cancel each other out. **This cancellation of cross-magnetisation is automatic and for all loads because both are produced by the same armature current.**

The distinction between the interpoles and compensating windings should be clearly understood. Both are connected in series and their m.m.fs. are such as to neutralize armature reaction. But compoles additionally supply m.m.f. for counteracting the reactance voltage induced in the coil undergoing commutation. Moreover, the action of the compoles is localized, they have negligible effect on the armature reaction occurring on the remainder of the armature periphery.

Fig. 27.13

Fig. 27.14

Fig. 27.15

**Example 27.13.** Determine the number of turns on each commutating pole of a 6-pole machine, if the flux density in the air-gap of the commutating pole =  $0.5 \text{ Wb/m}^2$  at full load and the effective length of the air-gap is 4 mm. The full-load current is 500 A and the armature is lap-wound with 540 conductors. Assume the ampere turns required for the remainder of the magnetic circuit to be one-tenth of that the air gap. **(Advanced Elect. Machines AMIE Sec.B, 1991)**

**Solution.** It should be kept in mind that compole winding must be sufficient to oppose the armature m.m.f. (which is directed along compole axis) and to provide the m.m.f. for compole air-gap and its magnetic circuit.

$$\therefore N_{CP} I_a = Z I_c / 2P + B_g l_g / \mu_0$$

where  $N_{CP}$  = No. of turns on the compole ;  $I_a$  = Armature current

$Z$  = No. of armature conductors ;  $I_c$  = Coil current

$P$  = No. of poles ;  $l_g$  = Air-gap length under the compole

$Z = 540$  ;  $I_a = 500 \text{ A}$  ;  $I_c = 500/6 \text{ A}$  ;  $P = 6$

$$\therefore \text{Arm. m.m.f.} = 540 \times (500/6) / 2 \times 6 = 3750$$

Compole air-gap m.m.f. =  $B_g \times l_g / \mu_0 = 0.5 \times 4 \times 10^{-3} / 4\pi \times 10^{-7} = 1591$   
 m.m.f. reqd. for the rest of the magnetic circuit = 10% of 1591 = 159  
 $\therefore$  Total compole air-gap m.m.f. = 1591 + 159 = 1750  
 Total m.m.f. reqd. = 3750 + 1750 = 5500  
 $\therefore N_{cp} I_a = 5500$  or  $N_{cp} = 5500/500 = 11$

### 27.13. Equalizing Connections

It is characteristic of lap -winding that all conductors in any parallel path lie under one pair of poles. If fluxes from all poles are exactly the same, then e.m.f. induced in each parallel path is the same and each path carries the same current. But despite best efforts, some inequalities in flux inevitably occur due either to slight variations in air-gap length or in the magnetic properties of steel. Hence, there is always a slight imbalance of e.m.f. in the various parallel paths. The result is that conductors under stronger poles generate greater e.m.f. and hence carry larger current. The current distribution at the brushes becomes unequal. Some brushes are overloaded *i.e.* carry more than their normal current whereas others carry less. Overloaded brushes spark badly whatever their position may be. This results in poor commutation and may even limit the output of the machine.

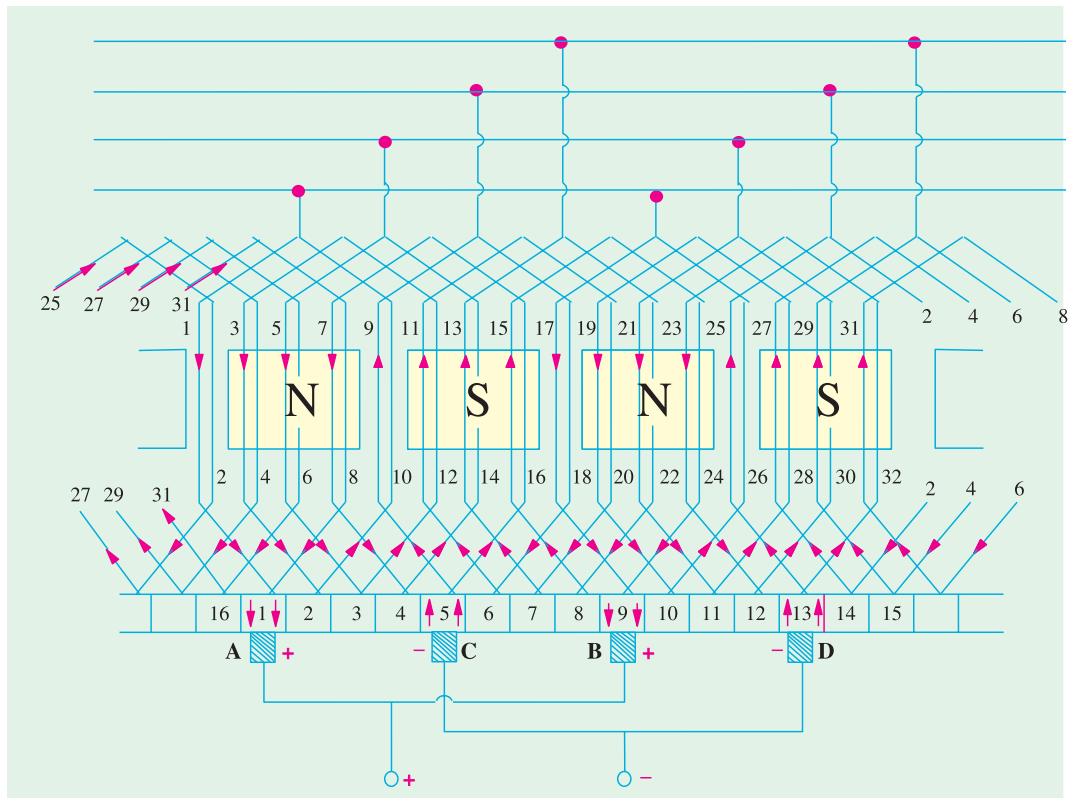

Fig. 27.16

By connecting together a number of symmetrical points on armature winding which would be at equal potential if the pole fluxes were equal, the difference in brush currents is diminished. This requires that there should be a whole number of slots per pair of poles so that, for example, if there is a slot under the centre of a *N*-pole, at some instant, then there would be one slot under the centre of every other *N*-pole. The equalizing conductors, which are in the form of Cu rings at the armature back and which connect such points are called *Equalizer Rings*. The circulating current due to the

slight difference in the e.m.fs. of various parallel paths, passes through these *equalizer rings* instead of passing through the brushes.

**Hence, the function of equalizer rings is to avoid unequal distribution of current at the brushes thereby helping to get sparkless commutation.**

One equalizer ring is connected to all conductors in the armature which are two poles apart (Fig. 27.17). For example, if the number of poles is 6, then the number of connections for each equalizer ring is 3 *i.e.* equal to the number of pair of poles.

Fig. 27.17

Maximum number of equalizer rings is equal to the number of conductors under one pair of poles. Hence, number of rings is

$$= \frac{\text{No. of conductors}}{\text{No. of pair of poles}}$$

In practice, however, the number of rings is limited to 20 on the largest machines and less on smaller machines. In Fig. 27.16 is shown a developed armature winding. Here, only 4 equalizing bars have been used. It will be seen that the number of equalizing connections to each bar is two *i.e.* half the number of poles. Each alternate coil has been connected to the bar. In this case, the winding is said to be 50% equalized. If all conductors were connected to the equalizer rings, then the winding would have been 100% equalized.

Equalizer rings are not used in wave-wound armatures, because there is no imbalance in the e.m.fs. of the two parallel paths. This is due to the fact that armature conductors in either parallel path are not confined under one pair of poles as in lap-winding but are distributed under all poles. Hence, even if there are inequalities in the pole flux, they will affect each path equally.

#### 27.14. Parallel Operation of Shunt Generators

Power plants, whether in d.c. or a.c. stations, will be generally found to have several smaller generators running in parallel rather than large single units capable of supplying the maximum peak load. These smaller units can be run single or in various parallel combinations to suit the actual load demand. Such practice is considered extremely desirable for the following reasons :

##### (i) Continuity of Service

Continuity of service is one of the most important requirements of any electrical apparatus. This would be impossible if the power plant consisted only of a single unit, because in the event of breakdown of the prime mover or the generator itself, the entire station will be shut down. In recent years, the requirement of uninterrupted service has become so important especially in factories etc. that it is now recognized as an economic necessity.

##### (ii) Efficiency

Usually, the load on the electrical power plant fluctuates between its peak value sometimes during the day and its minimum value during the late night hours. Since generators operate most efficiently when delivering full load, it is economical to use a single small unit when the load is light. Then, as the load demand increases, a larger generator can be substituted for the smaller one or another smaller unit can be connected to run in parallel with the one already in operation.

Equalizer rings

**(iii) Maintenance and Repair**

It is considered a good practice to inspect generators carefully and periodically to forestall any possibility of failure or breakdown. This is possible only when the generator is at rest which means that there must be other generators to take care of the load. Moreover, when the generator does actually breakdown, it can be repaired with more care and not in a rush, provided there are other generators available to maintain service.

**(iv) Additions to Plant**

Additions to power plants are frequently made in order to deliver increasingly greater loads. Provision for future extension is, in fact, made by the design engineers from the beginning. It becomes easy to add other generators for parallel operation as the load demand increases.

**27.15. Paralleling DC Generator**

Whenever generators are in parallel, their +ve and -ve terminals are respectively connected to the +ve and -ve sides of the bus-bars. These bus-bars are heavy thick copper bars and they act as +ve and -ve terminals for the whole power station. If polarity of the incoming generator is not the same as the line polarity, a serious short-circuit will occur when  $S_1$  is closed.

Moreover, paralleling a generator with reverse polarity effectively short-circuits it and results in damaged brushes, a damaged commutator and a blacked-out plant. Generators that have been tripped off the bus-bar because of a heavy fault current should always be checked for reversed polarity before paralleling.

In Fig. 27.18 is shown a shunt generator No. 1 connected across the bus-bars  $BB$  and supplying some of the load. For putting generator No. 2 in parallel with it the following procedure is adopted.

The armature of generator No. 2 is speeded by the prime-mover up to its rated value and then switch  $S_2$  is closed and circuit is completed by putting a voltmeter  $V$  across the open switch  $S_1$ . The excitation of the incoming generator No. 2 is changed till  $V$  reads zero. Then it means that its terminal voltage is the same as that of generator No. 1 or bus-bar voltage. After this, switch  $S_1$  is closed and so the incoming machine is paralleled to the system. Under these conditions, however, generator No. 2 is not taking any load, because its induced e.m.f. is the same as bus-bar voltage and there can be no flow of current between two points at the same potential. The generator is said to be 'floating' on the bus-bar. If generator No. 2 is to deliver any current, then its induced e.m.f.  $E$  should be greater than the bus-bar voltage  $V$ . In that case, current supplied by it is  $I = (E - V)/R_a$  where  $R_a$  is the resistance of the armature circuit. The induced e.m.f. of the incoming generator is increased by strengthening its field till it takes its proper share of load. At the same time, it may be found necessary to weaken the field of generator No. 1 to maintain the bus-bar voltage  $V$  constant.

Fig. 27.18

**27.16. Load Sharing**

Because of their slightly drooping voltage characteristics, shunt generators are most suited for stable parallel operation. Their satisfactory operation is due to the fact that any tendency on the part of a generator to take more or less than its proper share of load results in certain changes of voltage in the system which immediately oppose this tendency thereby restoring the original division of load. Hence, once paralleled, they are automatically held in parallel.

Similarly, for taking a generator out of service, its field is weakened and that of the other generator is increased till the ammeter of the generator to be cleared reads zero. After that, its breaker and then the switch are opened thus removing the generator out of service. This method of connecting in and removing a generator from service helps in preventing any shock or sudden disturbance to the prime-mover or to the system itself.

It is obvious that if the field of one generator is weakened too much, then power will be delivered to it and it will run in its original direction as a motor, thus driving its prime-mover.

In Fig. 27.19. and 27.20 are shown the voltage characteristics of two shunt generators. It is seen that for a common terminal voltage  $V$ , the generator No. 1 delivers  $I_1$  amperes and generator No. 2,  $I_2$  amperes. It is seen that generator No. 1, having more drooping characteristic, delivers less current. It is found that two shunt generators will divide the load properly at all points if their characteristics are similar in form and each has the same voltage drop from no-load to full-load.

If it desired that two generators of different kW ratings automatically share a load in proportion to their ratings, then their external characteristics when plotted in terms of their percentage full-load currents (not actual currents) must be identical as shown in Fig. 27.21. If, for example, a 100-kW generator is working in parallel with a 200-kW generator to supply a total of 240-kW, then first generator will supply 80 kW and the other 160 kW.

When the individual characteristics of the generators are known, their combined characteristics can be drawn by adding the separate currents at a number of equal voltage (because generators are running in parallel). From this combined characteristic, the voltage for any combined load can be read off and from there, the current supplies by each generator can be found (Fig. 27.20).

If the generators have straight line characteristics, then the above result can be obtained by simple calculations instead of graphically.

Let us discuss the load sharing of two generators which have unequal no-load voltages.

Fig. 27.19

Fig. 27.20

Fig. 27.21

Let  $E_1, E_2$  = no-load voltages of the two generators  
 $R_1, R_2$  = their armature resistances  
 $V$  = common terminal voltage

Then  $I_1 = \frac{E_1 - V}{R_1}$  and  $I_2 = \frac{E_2 - V}{R_2}$

$$\therefore \frac{I_2}{I_1} = \frac{E_2 - V}{E_1 - V} \cdot \frac{R_1}{R_2} = \frac{K_2 N_2 \Phi_2 - V}{K_1 N_1 \Phi_1 - V} \cdot \frac{R_1}{R_2}$$

From the above equation, it is clear that bus-bar voltage can be kept constant (and load can be transferred from 1 to 2) by increasing  $\Phi_2$  or  $N_2$  or by reducing  $N_1$  and  $\Phi_1$ .  $N_2$  and  $N_1$  are changed by changing the speed of driving engines and  $\Phi_1$  and  $\Phi_2$  are changed with the help of regulating shunt field resistances.

It should be kept in mind that

- (i) Two parallel shunt generators having equal no-load voltages share the load in such a ratio that the load current of each machine produces the same drop in each generator.
- (ii) In the case of two parallel generators having unequal no-load voltages, the load currents produce sufficient voltage drops in each so as to keep their terminal voltage the same.
- (iii) The generator with the least drop assumes greater share of the change in bus load.
- (iv) Paralleled generators with different power ratings but the same voltage regulation will divide any oncoming bus load in direct proportion to their respective power ratings (Ex. 27.14).

### 27.17. Procedure for Paralleling D.C. Generators

- (i) Close the disconnect switch of the incoming generator
- (ii) Start the prime-mover and adjust it to the rated speed of the machine
- (iii) Adjust the voltage of the incoming machine a few volts higher than the bus voltage
- (iv) Close the breaker of the incoming generator
- (v) Turn the shunt field rheostat of the incoming machine in the raise-voltage direction and that of the other machine(s) already connected to the bus in the lower-voltage direction till the desired load distribution (as indicated by the ammeters) is achieved.

### 27.18. Compound Generators in Parallel

In Fig. 27.22 are shown two compound generators (designated as No. 1 and No. 2) running in parallel. Because of the rising characteristics of the usual compounded generators, it is obvious that in the absence of any corrective devices, the parallel operation of such generators is unstable. Let us suppose that, to begin with, each generator is taking its proper share of load. Let us now assume that for some reason, generator No. 1 takes a slightly increased load. In that case, the current passing through its series winding increases which further strengthens its field and so raises its generated e.m.f. thus causing it to take still more load. Since the system load is assumed to be constant, generator No. 2 will drop some of its load, thereby weakening its series field which will result in its further dropping off its load. Since this effect is cumulative, Generator No. 1 will, therefore, tend to take the entire load and finally drive generator No. 2 as a motor. The circuit breaker of at least one of the two generators will open, thus stopping their parallel operation.

For making the parallel operation of over-compound and level-compound generators stable,\* they are always used with an equalizer bar (Fig. 27.22) connected to the armature ends of the series coils of the generators. The equalizer bar is a conductor of low resistance and its operation is as follows :

Fig. 27.22

\* Like shunt generators, the under-compound generators also do not need equalizers for satisfactory parallel operation.

Suppose that generator No. 1 starts taking more than its proper share of load. Its series field current is increased. But now this increased current passes partly through the series field coil of generator No. 1 and partly it flows via the equalizer bar through the series field winding of generator No. 2. Hence, the generators are affected in a similar manner with the result the generator No. 1 cannot take the entire load. For maintaining proper division of load from no-load to full-load, it is essential that

- (i) the regulation of each generator is the same.
- (ii) the series field resistances are inversely proportional to the generator rating.

### 27.19. Series Generators in Parallel

Fig 27.23 shows two identical series generators connected in parallel. Suppose  $E_1$  and  $E_2$  are initially equal, generators supply equal currents and have equal shunt resistances. Suppose  $E_1$  increases slightly so that  $E_1 > E_2$ . In that case,  $I_1$  becomes greater than  $I_2$ . Consequently, field of machine 1 is strengthened thus increasing  $E_1$  further whilst the field of machine 2 is weakened thus decreasing  $E_2$  further. A final stage is reached when machine 1 supplies not only the whole load but also supplies power to machine 2 which starts running as a motor.

Fig. 27.23

Obviously, the two

machines will form a short-circuited loop and the current will rise indefinitely. This condition can be prevented by using equalizing bar because of which two similar machines pass approximately equal currents to the load, the slight difference between the two currents being confined to the loop made by the armatures and the equalizer bar.

**Example 27.14.** A 100-kW, 250-V generator is paralleled with a 300 kW, 250-V generator. Both generators have the same voltage regulation. The first generator is supplying a current of 200 A and the other 500 A. What would be the current supplied by each generator if an additional load of 600 A is connected to the bus ?

**Solution.** As explained in Art. 27.17, this additional load would be divided in direct proportion to the respective power ratings of the two generators.

$$\Delta I_1 = \left( \frac{100}{100 + 300} \right) \times 600 = 150 \text{ A ;}$$

$$\Delta I_2 = \left( \frac{300}{100 + 300} \right) \times 600 = 450 \text{ A}$$

**Example 27.15.** Two 220-V, d.c. generators, each having linear external characteristics, operate in parallel. One machine has a terminal voltage of 270 V on no-load and 220 V at a load current of 35 A, while the other has a voltage of 280 V at no-load and 220 V at 50 A. Calculate the output current of each machine and the bus-bar voltage when the total load is 60 A. What is the kW output of each machine under this condition ?

**Solution. Generator No. 1.**

Voltage drop for 35 A = 270 – 220 = 50 V

∴ Voltage drop/ampere = 50/35 = 10/7 V/A

**Generator No. 2**

Voltage drop/ampere =  $(280-220)/50 = 1.2 \text{ V/A}$

Let  $V =$  bus-bar voltage

$I_1 =$  current output of generator No.1

$I_2 =$  current output of generator No.2

then  $V = 270 - (10/7) I_1$  ...for generator No. 1  
 $= 280 - 1.2 I_2$  ...for generator No. 2

Since bus-bar voltage is the same.

$\therefore 270 - 10 I_1/7 = 280 - 1.2 I_2$  or  $4.2 I_2 - 5 I_1 = 35$  ...**(i)**

Also  $I_1 + I_2 = 60$  ...**(ii)**

Solving the two equations, we get  $I_1 = 23.6 \text{ A}; I_2 = 36.4 \text{ A}$

Now  $V = 280 - 1.2 I_2 = 280 - 1.2 \times 36.4$   
 $= 236.3 \text{ V}$

Output of 1st machine  
 $= 236.3 \times 23.6/1000$   
 $= 5.577 \text{ kW}$

Output of 2nd machine  
 $= 236.3 \times 36.4/1000$   
 $= 8.602 \text{ kW}$

**Graphical Solution.**

In Fig. 27.24, total load current of 60 A has been plotted along X-axis and the terminal voltage along Y-axis. The linear characteristics of the two generators are drawn from the given data. The common bus-bar voltage is given by the point of intersection of the two graphs. From the graph, it is seen that  $V = 236.3 \text{ V}; I_1 = 23.6 \text{ A}; I_2 = 36.4 \text{ A}$ .

**Fig. 27.24**

**Example 27.16.** Two shunt generators each with an armature resistance of  $20 \Omega$  and field resistance of  $0.01 \Omega$  run in parallel and supply a total load of 4000 A. The e.m.f.s are respectively 210 V and 220 V. Calculate the bus-bar voltage and output of each machine. **(Electrical Machines-1, South Gujarat Univ. 1988)**

**Solution.** Generators are shown in Fig. 27.25.

Let  $V =$  bus-bar voltage

$I_1 =$  output current of  $G_1$

$I_2 =$  output current of  $G_2$

Now,  $I_1 + I_2 = 4000 \text{ A}, I_{sh} = V/20$ .

$I_{a1} = (I_1 + V/20); I_{a2} = (I_2 + V/20)$

In each machine,

$V +$  armature drop = induced e.m.f.

$\therefore V + I_{a1} R_a = E_1$

**Fig. 27.25**

$$\text{or } V + (I_1 + V/20) \times 0.01$$

$$= 210 \quad \dots 1\text{st machine}$$

$$\text{Also } V + I_{a2} R_a = E_2$$

$$\text{or } V + (I_2 + V/20) \times 0.01 = 220 \quad \dots 2\text{nd machine}$$

$$\text{Subtracting, we have } 0.01 (I_1 - I_2) = 10 \text{ or } I_1 - I_2 = 1000$$

$$\text{Also, } I_1 + I_2 = 4000 \text{ A } \therefore I_1 = \mathbf{2500 \text{ A}} ; I_2 = \mathbf{1500 \text{ A}}$$

Substituting the value of  $I_1$  above, we get

$$V + (2500 + V/20) \times 0.01 = 210 \quad \therefore V = \mathbf{184.9 \text{ V}}$$

$$\text{Output of 1st generator} = 184.9 \times 2500/1000 = \mathbf{462.25 \text{ kW}}$$

$$\text{Output of 2nd generator} = 184.9 \times 1500/1000 = \mathbf{277.35 \text{ kW}}$$

**Example 27.17.** Two shunt generators operating in parallel deliver a total current of 250 A. One of the generators is rated 50 kW and the other 100 kW. The voltage rating of both machine is 500 V and have regulations of 6 per cent (smaller one) and 4 per cent. Assuming linear characteristics, determine (a) the current delivered by each machine (b) terminal voltage.

(Elect. Machines, Nagpur Univ. 1991)

**Solution. 50 kW generator**

$$\text{F.L. voltage drop} = 500 \times 0.06 = 30 \text{ V} ; \text{F.L. current} = 50,000/500 = 100 \text{ A}$$

$$\text{Drop per ampere} = 30/100 = 3/10 \text{ V/A}$$

**100 kW generator**

$$\text{F.L. drop} = 500 \times 0.04 = 20 \text{ V} ; \text{F.L. current} = 100,000/5000 = 200 \text{ A}$$

$$\text{Drop per ampere} = 20/200 = 1/10 \text{ V/A}$$

If  $I_1$  and  $I_2$  are currents supplied by the two generators and  $V$  the terminal voltage, then

$$V = 500 - (3I_1/10) \quad \dots 1\text{st generator}$$

$$= 500 - (I_2/10) \quad \dots 2\text{nd generator}$$

$$\therefore 3I_1/10 = I_2/10 \text{ or } 3I_1 = I_2 ; \quad \text{Also } I_1 + I_2 = 250 \quad \dots \text{given}$$

$$\text{(a) Solving the above two equations, we get } I_1 = \mathbf{62.5 \text{ A}} ; I_2 = \mathbf{187.5 \text{ A}}$$

$$\text{(b) } V = 500 - (3 \times 62.5/10) = \mathbf{481.25 \text{ V}}$$

**Example 27.18.** Two shunt generators, each with a no-load voltage of 125 V are running parallel. Their external characteristics can be taken as straight lines over this operating ranges. Generator No. 1 is rated at 25 kW and its full-load voltage is 119 V, Generator No. 2 is rated at 200 kW at 116 V. Calculate the bus-bar voltage when the total load is 3500 A. How is the load divided between the two ?

(Elect. Machinery - I, Mysore Univ. 1988)

**Solution.** Let  $V$  = bus-bar voltage

$$x_1, x_2 = \text{load carried by each generator in terms of percentage of rated load}$$

$$P_1, P_2 = \text{load carried by each generator in watts}$$

$$V = 125 - [(125 - 119) (x_1/100)] \quad \dots \text{Generator No. 1}$$

$$V = 125 - [(125 - 116) (x_2/100)] \quad \dots \text{Generator No. 2}$$

$$\therefore 125 - \frac{6x_1}{100} = 125 - \frac{9x_2}{100} \quad x_2 = \frac{6x_1}{9} = \frac{2x_1}{3}$$

Since in d.c. circuits, power delivered is given by  $VI$  watt, the load on both generators is

$$\left(250 x_1 \times \frac{1000}{100}\right) + \left(200 x_2 \times \frac{1000}{100}\right) = V \times 3500$$

Now, replacing  $V$  and  $x_2$  by terms involving  $x_1$ , we get as a result

$$\left(250 x_1 \times \frac{1000}{100}\right) + \left(200 \times \frac{2x_1}{3} \times \frac{1000}{100}\right) = \left(125 - \frac{6x_1}{100}\right) \times 3500$$

$$x_1 = 108.2 \text{ per cent}$$

$$\therefore \text{Bus-bar voltage } V = 125 - (6 \times 108.2/100) = \mathbf{118.5 \text{ V}}$$

The division of load between the two generators can be found thus :

$$x_1 = \frac{P_1 \times 1000}{250,000} \quad \text{and} \quad x_2 = \frac{P_2 \times 1000}{200,000}$$

$$\therefore \frac{x_1}{x_2} = \frac{P_1 \times 200,000}{P_2 \times 250,000} = \frac{4P_1}{5P_2} = \frac{3}{2} \quad \therefore \frac{3}{2} = \frac{4P_1}{5P_2} = \frac{4VI_1}{5VI_2} = \frac{4I_1}{5I_2} \quad \dots(i)$$

$$\text{Since} \quad I_1 + I_2 = 3500 \quad \therefore I_2 = 3500 - I_1$$

$$\text{Hence (i) above becomes, } \frac{3}{2} = \frac{4I_1}{5(3500 - I_1)}$$

$$\therefore I_1 = \mathbf{2,283 \text{ A}} \quad \text{and} \quad I_2 = \mathbf{1,217 \text{ A}}$$

**Example 27.19.** Two shunt generators A & B operate in parallel and their load-characteristics may be taken as straight lines. The voltage of generator A falls from 240 V at no load to 220 V at 200 A, while that of B falls from 245 V at no load to 220 V to 150 A. Determine the currents supplied by each machine to a common load of 300 A and the bus-bar voltage.

(Bharathithasan Univ. April 1997)

**Solution.** Two graphs are plotted as shown in Fig. 27.26.

Their equations are :

$$240 - (20/200) I_A = 245 - (25/150) I_B$$

$$\text{Further, } I_A + I_B = 300$$

Fig. 27.26. Parallel operation of two D.C. Generators

This gives  $I_A = 168.75 \text{ A}$ ,  $I_B = 131.25 \text{ A}$

And common voltage of Bus-bar,  $V_{BUS}$

$$= 240 - (20/200) \times 168.75, \text{ or}$$

$$V_{BUS} = 245 - (25/150) \times 131.25 = 223.125 \text{ volts.}$$

It is represented by the point C, in graph, as an intersection, satisfying the condition that two currents ( $I_A$  and  $I_B$ ) add up to 300 amp.

**Example 27.20.** In a certain sub-station, there are 5 d.c. shunt generators in parallel, each having an armature resistance of  $0.1 \Omega$ , running at the same speed and excited to give equal induced e.m.f.s. Each generator supplies an equal share of a total load of 250 kW at a terminal voltage of 500 V into a load of fixed resistance. If the field current of one generator is raised by 4%, the others remaining unchanged, calculate the power output of each machine and their terminal voltages under these conditions. Assume that the speeds remain constant and flux is proportional to field current. (Elect. Technology, Allahabad Univ. 1991)

**Solution.** Generator connections are shown in Fig. 27.27.

Load supplied by each =  $250/5 = 50 \text{ kW}$

$\therefore$  Output of each =  $50,000/500 = 100 \text{ A}$

Terminal voltage of each = 500 V

Armature drop of each =  $0.1 \times 100 = 10 \text{ V}$

Hence, induced e.m.f. of each = 510 V

When field current of one is increased, its flux and hence its generated e.m.f. is increased by 4%. Now, 4% of 510 V = 20.4 V

$\therefore$  Induced e.m.f. of one =  $510 + 20.4 = 530.4 \text{ V}$

Let  $I_1$  = current supplied by one generator after increased excitation

$I_2$  = current supplied by each of the other 4 generators

$V$  = new terminal or bus-bar voltage

$$\therefore 530.4 - 0.1 I_1 = V \quad \dots(i)$$

$$510 - 0.1 I_2 = V \quad \dots(ii)$$

Now, fixed resistance of load =  $500/500 = 1 \Omega$ ; Total load current =  $I_1 + 4I_2$

$$\therefore 1 \times (I_1 + 4I_2) = V \text{ or } I_1 + 4I_2 = V \quad \dots(iii)$$

Subtracting (ii) from (i), we get,  $I_1 - I_2 = 20.4$  ... (iv)

Subtracting (iii) from (ii), we have  $I_1 + 4.1 I_2 = 510$  ... (v)

From (iv) and (v), we get  $I_2 = 3060/51 = 59.99 = 60 \text{ A (approx.)}$

From (iv)  $I_1 = 20.4 + 60 = 264 \text{ A}$

From (iii)  $V = 264 + 240 = 504 \text{ Volt}$

Output of 1st machine =  $504 \times 264 \text{ watt} = 133 \text{ kW}$

Output of each of other four generators =  $504 \times 60 \text{ W} = 30.24 \text{ kW}$

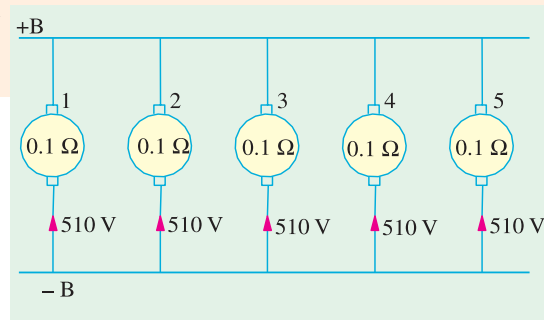

Fig. 27.27

**Example 27.21.** Two d.c. generators are connected in parallel to supply a load of 1500 A. One generator has an armature resistance of  $0.5 \Omega$  and an e.m.f. of 400 V while the other has an armature resistance of  $0.04 \Omega$  and an e.m.f. of 440 V. The resistances of shunt fields are  $100 \Omega$  and  $80 \Omega$  respectively. Calculate the currents  $I_1$  and  $I_2$  supplied by individual generator and terminal voltage  $V$  of the combination. (Power Apparatus-I, Delhi Univ. Dec. 1987)

**Solution.** Generator connection diagram is shown in Fig. 27.28.

Let  $V$  = bus-bar voltage

$I_1$  = output current of one generator

$$I_2 = \text{output current of other generator} \\ = (1500 - I_1)$$

$$\text{Now, } I_{sh1} = V/100 \text{ A ; } I_{sh2} = V/80 \text{ A}$$

$$I_{a1} = \left( I_1 + \frac{V}{100} \right) \text{ and } I_{a2} = \left( I_2 + \frac{V}{80} \right)$$

$$\text{or } I_{a2} = \left( 1500 - I_1 + \frac{V}{80} \right)$$

For each machine

$$E - \text{armature drop} = V \\ \therefore 400 - \left( I_1 + \frac{V}{100} \right) \times 0.5 = V$$

$$\text{or } 400 - 0.5 I_1 - 0.005 V = V \text{ or } 0.5 I_1 = 400 - 1.0005 V \quad \dots(i)$$

$$\text{Also } 440 - (1500 - I_1 + \frac{V}{80}) \times 0.04 = V \text{ or } 0.04 I_1 = 1.0005 V - 380 \quad \dots(ii)$$

Dividing Eq. (i) by (ii), we get

$$\frac{0.5 I_1}{0.04 I_2} = \frac{400 - 1.0005 V}{1.0005 V - 380} \therefore V = \mathbf{381.2 \text{ V}}$$

Substituting this value of  $V$  in Eq. (i), we get  $0.5 I_1 = 400 - 1.0005 \times 381.2$

$$\therefore I_1 = \mathbf{33.8 \text{ A}} ; I_2 = 1500 - 33.8 = \mathbf{1466.2 \text{ A}}$$

$$\text{Output of 1st generator} = 381.2 \times 33.8 \times 10^{-3} = \mathbf{12.88 \text{ kW}}$$

$$\text{Output of 2nd generator} = 381.2 \times 1466.2 \times 10^{-3} = \mathbf{558.9 \text{ kW}}$$

**Example 27.22.** Two shunt generators and a battery are working in parallel. The open circuit voltage, armature and field resistances of generators are 250 V, 0.24  $\Omega$ , 100  $\Omega$  are 248 V, 0.12  $\Omega$  and 100  $\Omega$  respectively. If the generators supply the same current when the load on the bus-bars is 40 A, calculate the e.m.f. of the battery if its internal resistance is 0.172  $\Omega$ .

**Solution.** Parallel combination is shown in Fig. 27.29.

Values of currents and induced e.m.fs. are shown in the diagram.

$$V + \left( I + \frac{V}{100} \right) \times 0.24 = 250 \quad \dots(i)$$

$$V + \left( I + \frac{V}{100} \right) \times 0.12 = 248 \quad \dots(ii)$$

$$\text{Also } I + I + I_b = 40$$

$$I_b + 2I = 40 \quad \dots(iii)$$

$$\text{Subtracting (iii) from (i), we get } \left( I + \frac{V}{100} \right) \times 0.12 = 2 \quad \dots(iv)$$

Putting this value in (ii) above,  $V = 246$  volt.

$$\text{Putting this value of } V \text{ in (iv), } \left( I + \frac{246}{100} \right) \times 0.12 = 2 \quad \dots(v)$$

$$\therefore I = 50/3 - 2.46 = 14.2 \text{ A}$$

From (iii), we have  $I_b = 40 - (2 \times 14.2) = 11.6 \text{ A}$

$$\text{Internal voltage drop in battery} = 11.6 \times 0.172 = 2 \text{ V } \therefore E_b = 246 + 2 = \mathbf{248 \text{ V}}$$

Fig. 27.28

Fig. 27.29

**Example 27.23.** Two d.c. generators A and B are connected to a common load. A had a constant e.m.f. of 400 V and internal resistance of 0.25  $\Omega$  while B has a constant e.m.f. of 410 V and an internal resistance of 0.4  $\Omega$ . Calculate the current and power output from each generator if the load voltage is 390 V. What would be the current and power from each and the terminal voltage if the load was open-circuited ?  
(Elect. Engg; I, Bangalore Univ. 1987)

**Solution.** The generator connections are shown in Fig. 27.30 (a).

Fig. 27.30

Since the terminal or output voltage is 390 V, hence

$$\text{Load supplied by A} = (400 - 390)/0.25 = \mathbf{40 \text{ A}}$$

$$\text{Load supplied by B} = (410 - 390)/0.4 = \mathbf{50 \text{ A}}$$

$$\therefore \text{Power output from A} = 40 \times 390 = \mathbf{15.6 \text{ kW}}$$

$$\text{Power output from B} = 50 \times 390 = \mathbf{19.5 \text{ kW}}$$

If the load is open-circuited as shown in Fig. 27.30.(b), then the two generators are put in series with each other and a circulatory current is set up between them.

$$\text{Net voltage in the circuit} = 410 - 400 = 10 \text{ V}$$

$$\text{Total resistance} = 0.4 + 0.25 = 0.65 \Omega$$

$$\therefore \text{circulatory current} = 10/0.65 = 15.4 \text{ A}$$

$$\text{The terminal voltage} = 400 + (15.4 \times 0.25) = \mathbf{403.8 \text{ V}}$$

Obviously, machine B with a higher e.m.f. acts as a generator and drives machine A as a motor.

$$\text{Power taken by A from B} = 403.8 \times 15.4 = \mathbf{6,219 \text{ W}}$$

Part of this appears as mechanical output and the rest is dissipated as armature Cu loss.

Mechanical output =  $400 \times 15.4 = 6.16 \text{ kW}$  ; Armature Cu loss =  $3.8 \times 15.4 = 59 \text{ W}$

Power supplied by B to A =  $6,219 \text{ W}$  ; Armature Cu loss =  $6.16 \times 15.4 = 95 \text{ W}$

**Example 27.24.** Two compound generators A and B, fitted with an equalizing bar, supply a total load current of 500 A. The data regarding the machines are :

	A	B
Armature resistance (ohm)	0.01	0.02
Series field winding (ohm)	0.004	0.006
Generated e.m.fs. (volt)	240	244

Calculate (a) current in each armature (b) current in each series winding (c) the current flowing in the equalizer bar and (d) the bus-bar voltage. Shunt currents may be neglected.

**Solution.** The two generators (with their shunt windings omitted) are shown in Fig. 27.31.

Let  $V$  = bus-bar voltage ;  $v$  = voltage between equalizer bus-bar and the negative

tors  
 $i_1, i_2$  = armature currents of the two generators

$$\text{Now, } i_1 + i_2 = 500$$

$$\text{or } \frac{240-v}{0.01} + \frac{244-v}{0.02} = 500$$

Multiplying both sides by  $\frac{1}{100}$  we get

$$240 - v + 122 - (v/2) = 500$$

$$\therefore v = 238 \text{ volts}$$

$$(a) \therefore i_1 = \frac{240-238}{0.01} = 200 \text{ A}$$

$$i_2 = \frac{244-238}{0.02} = 300 \text{ A}$$

(b) The total current of 500 A divides between the series windings in the inverse ratio of their resistance i.e. in the ratio of  $\frac{1}{0.004} : \frac{1}{0.006}$  or in the ratio 3 : 2.

Hence, current in the series winding of generator A =  $500 \times \frac{3}{5} = 300 \text{ A}$

Similarly, current in the series winding of generator B =  $500 \times \frac{2}{5} = 200 \text{ A}$

(c) It is obvious that a current of 100 A flows in the equalizing bar from C to D. It is so because the armature current of generator A is 200 A only. It means that 100 A comes from the armature of generator, B, thus making 300 A for the series field winding of generator A.

(d)  $V = v - \text{voltage drop in one series winding} = 238 - (300 \times 0.004) = 236.8 \text{ V}$

Fig. 27.31

### Tutorial Problem No. 27.2

1. Two separately-excited d.c. generators are connected in parallel supply a load of 200 A. The machines have armature circuit resistances of  $0.05 \Omega$  and  $0.1 \Omega$  and induced e.m.fs. 425 V and 440 V respectively. Determine the terminal voltage, current and power output of each machine. The effect of armature reaction is to be neglected. **(423.3 V ; 33.3 A ; 14.1 kW ; 166.7 A ; 70.6 kW)**

2. Two shunt generators operating in parallel given a total output of 600 A. One machine has an armature resistance of  $0.02 \Omega$  and a generated voltage of 455 V and the other an armature resistance of  $0.025 \Omega$  and a generated voltage of 460 V. Calculate the terminal voltage and the kilowatt output of each machine. Neglect field currents. **(450.56 V ; 100 kW ; 170.2 kW)**

3. The external characteristics of two d.c. shunt generators *A* and *B* are straight lines over the working range between no-load and full-load.

	<i>Generator A</i>		<i>Generator B</i>	
	<i>No-load</i>	<i>Full-load</i>	<i>No-load</i>	<i>Full-load</i>
Terminal P.D. (V)	400	360	420	370
Load current (A)	0	80	0	70

Determine the common terminal voltage and output current of each generator when sharing a total load of 100 A.

(57.7 A ; 42.3 A ; 378.8 V)

4. Two shunt generators operating in parallel have each an armature resistance of  $0.02 \Omega$ . The combined external load current is 2500 A. If the generated e.m.fs. of the machines are 560 V and 550 V respectively, calculate the bus-bar voltage and output in kW of each machine. (530 V ; 795 kW ; 530 kW)

5. Two shunt generators *A* and *B* operate in parallel and their load characteristics may be taken as straight lines. The voltage of *A* falls from 240 V at no-load to 220 V at 200 A, while that of *B* falls from 245 V at no-load to 220 V at 150 A. Determine the current which each machine supplies to a common load of 300 A and the bus-bar voltage at this load.

(169 A ; 131 A ; 223.1 V)

6. Two shunt-wound d.c. generators are connected in parallel to supply a load of 5,000 A. Each machine has an armature resistance of  $0.03 \Omega$  and a field resistance of  $60 \Omega$ , but the e.m.f. of one machine is 600 V and that of the other is 640 V. What power does each machine supply ?

(1,004 kW ; 1,730 kW including the fields)

7. Two shunt generators running in parallel share a load of 100 kW equally at a terminal voltage of 230 V. On no-load, their voltages rise to 240 V and 245 V respectively. Assuming that their volt-ampere characteristics are rectilinear, find how would they share the load when the total current is reduced to half its original value ? Also, find the new terminal voltage.

(20 kW ; 30 kW, 236 V)

8. Two generators, each having no-load voltage of 500 V, are connected in parallel to a constant resistance load consuming 400 kW. The terminal p.d. of one machine falls linearly to 470 V as the load is increased to 850 A while that of the other falls linearly to 460 V when the load is 600 A. Find the load current and voltage of each generator.

If the induced e.m.f. of one machine is increased to share load equally, find the new current and voltage.

( $I_1 = 626 \text{ A}$  ;  $I_2 = 313 \text{ A}$  ;  $V = 479 \text{ V}$  ;  $I = 469.5 \text{ A}$  ;  $V = 484.4 \text{ V}$ )

9. Estimate the number of turns needed on each interpole of a 6-pole generator delivering 200 kW at 200 V ; given : number of lap-connected armature conductors = 540 ; interpole air gap = 1.0 cm ; flux-density in interpole air-gap =  $0.3 \text{ Wb/m}^2$ . Ignore the effect of iron parts of the circuit and of leakage.

[10] (*Electrical Machines, B.H.U. 1980*)

## OBJECTIVE TEST – 27

- In d.c. generators, armature reaction is produced actually by
  - its field current
  - armature conductors
  - field pole winding
  - load current in armature
- In a d.c. generator, the effect of armature reaction on the main pole flux is to
  - reduce it
  - distort it
  - reverse it
  - both (a) and (b)
- In a clockwise-rotating loaded d.c. generator, brushes have to be shifted
  - clockwise
  - counterclockwise
  - either (a) or (b)
  - neither (a) nor (b).
- The primary reason for providing compensating windings in a d.c. generator is to
  - compensate for decrease in main flux
  - neutralize armature mmf
  - neutralize cross-magnetising flux
  - maintain uniform flux distribution.
- The main function of interpoles is to minimize ..... between the brushes and the commutator when the d.c. machine is loaded.
  - friction
  - sparking
  - current
  - wear and tear

6. In a 6-pole d.c. machine, 90 mechanical degrees correspond to ..... electrical degrees.  
 (a) 30 (b) 180  
 (c) 45 (d) 270
7. The most likely cause(s) of sparking at the brushes in a d.c. machine is /are  
 (a) open coil in the armature  
 (b) defective interpoles  
 (c) incorrect brush spring pressure  
 (d) all of the above
8. In a 10-pole, lap-wound d.c. generator, the number of active armature conductors per pole is 50. The number of compensating conductors per pole required is  
 (a) 5 (b) 50  
 (c) 500 (d) 10
9. The commutation process in a d.c. generator basically involves  
 (a) passage of current from moving armature to a stationary load  
 (b) reversal of current in an armature coil as it crosses MNA  
 (c) conversion of a.c. to d.c.  
 (d) suppression of reactance voltage
10. Point out the WRONG statement. In d.c. generators, commutation can be improved by  
 (a) using interpoles  
 (b) using carbon brushes in place of Cu brushes  
 (c) shifting brush axis in the direction of armature rotation  
 (d) none of the above
11. Each of the following statements regarding interpoles is true **except**  
 (a) they are small yoke-fixed poles spaced in between the main poles  
 (b) they are connected in parallel with the armature so that they carry part of the armature current  
 (c) their polarity, in the case of generators is the same as that of the main pole ahead  
 (d) they automatically neutralize not only reactance voltage but cross-magnetisation as well
12. Shunt generators are most suited for stable parallel operation because of their voltage characteristics.  
 (a) identical (b) dropping  
 (c) linear (d) rising
13. Two parallel shunt generators will divide the total load equally in proportion to their kilowatt output ratings only when they have the same  
 (a) rated voltage  
 (b) voltage regulation  
 (c) internal  $I_a R_a$  drops  
 (d) both (a) and (b)
14. The main function of an equalizer bar is to make the parallel operation of two over-compounded d.c. generators  
 (a) stable (b) possible  
 (c) regular (d) smooth
15. The *essential* condition for stable parallel operation of two d.c. generators having similar characteristics is that they should have  
 (a) same kilowatt output ratings  
 (b) dropping voltage characteristics  
 (c) same percentage regulation  
 (d) same no-load and full-load speed
16. The main factor which leads to unstable parallel operation of flat-and over-compound d.c. generators is  
 (a) unequal number of turns in their series field windings  
 (b) unequal series field resistances  
 (c) their rising voltage characteristics  
 (d) unequal speed regulation of their prime movers
17. The simplest way to shift load from one d.c. shunt generator running in parallel with another is to  
 (a) adjust their field rheostats  
 (b) insert resistance in their armature circuits  
 (c) adjust speeds of their prime movers  
 (d) use equalizer connections
18. Which one of the following types of generators does NOT need equalizers for satisfactory parallel operation ?  
 (a) series (b) over-compound  
 (c) flat-compound (d) under-compound.

## ANSWERS

1. (d) 2. (d) 3. (a) 4. (c) 5. (b) 6. (d) 7. (d) 8. (a) 9. (b) 10. (d) 11. (b)  
 12. (b) 13. (d) 14. (a) 15. (b) 16. (c) 17. (a) 18. (d)

- Critical Speed
- Voltage Build up of a Shunt Generator
- Conditions for Build-up of a Shunt Generator
- Other factors Affecting Voltage Building of a D.C. Generator
- External Characteristic
- Voltage Regulation
- Internal or Total Characteristic
- Series Generator
- Compound-wound Generator
- How to calculate Required Series Turns?
- Uses of D.C. Generators

## GENERATOR CHARACTERISTICS

**C** Generator characteristics gives the relation between terminal voltage and load current. It is of great importance in judging the suitability of a generator for a particular purpose

### 28.1. Characteristics of D.C. Generators

Following are the three *most* important characteristics or curves of a d.c. generator :

#### 1. No-load saturation Characteristic ( $E_0/I_f$ )

It is also known as Magnetic Characteristic or Open-circuit Characteristic (*O.C.C.*). It shows the relation between the no-load generated e.m.f. in armature,  $E_0$  and the field or exciting current  $I_f$  at a given fixed speed. It is just the magnetisation curve for the material of the electromagnets. Its shape is practically the same for all generators whether separately-excited or self-excited.

#### 2. Internal or Total Characteristic ( $E/I_a$ )

It gives the relation between the e.m.f.  $E$  actually induces in the armature (after allowing for the demagnetising effect of armature reaction) and the armature current  $I_a$ . This characteristic is of interest mainly to the designer and can be obtained as explained in Art. 28.12.

#### 3. External Characteristic ( $V/I$ )

It is also referred to as performance characteristic or sometimes voltage-regulating curve.

It gives relation between that terminal voltage  $V$  and the load current  $I$ . This curve lies below the internal characteristic because it takes into account the voltage drop over the armature circuit resistance. The values of  $V$  are obtained by subtracting  $I_a R_a$  from corresponding values of  $E$ . This characteristic is of great importance in judging the suitability of a generator for a particular purpose. It may be obtained in two ways (i) by making simultaneous measurements with a suitable voltmeter and an ammeter on a loaded generator (Art. 28.10) or (ii) graphically from the *O.C.C.* provided the armature and field resistances are known and also if the demagnetising effect (under rated load conditions) or the armature reaction (from the short-circuit test) is known.

### 28.2. Separately-excited Generator

#### (a) (i) No-load Saturation Characteristic ( $E_0/I_f$ )

The arrangement for obtaining the necessary data to plot this curve is shown in Fig. 28.1. The exciting or field current  $I_f$  is obtained from an external independent d.c. source. It can be varied from zero upwards by a potentiometer and its value read by an ammeter  $A$  connected in the field circuit as shown.

Now, the voltage equation of a d.c. generator is,  $E_g = \frac{\Phi ZN}{60} \times \left(\frac{P}{A}\right)$  volt

Fig. 28.1

Hence, if speed is constant, the above relation becomes  $E = k\Phi$

It is obvious that when  $I_f$  is increased from its initial small value, the flux  $\Phi$  and hence generated e.m.f.  $E_g$  increase directly as current so long as the poles are unsaturated. This is represented by the straight portion  $Od$  in Fig. 28.1 (b). But as the flux density increases, the poles become saturated, so a greater increase in  $I_f$  is required to produce a given increase in voltage than on the lower part of the curve. That is why the upper portion  $db$  of the curve  $Odb$  bends over as shown.

**(ii) Load Saturation Curve ( $V/I_f$ )**

The curve showing relation between the terminal voltage  $V$  and field current  $I_f$  when the generator is loaded, is known as Load Saturation Curve.

The curve can be deduced from the no-load saturation curve provided the values of armature reaction and armature resistance are known. While considering this curve, account is taken of the

Fig. 28.2

Fig. 28.3

demagnetising effect of armature reaction and the voltage drop in armature which are practically absent under no-load conditions. The no-load saturation curve of Fig. 28.1 has been repeated in Fig. 28.2 on a base of field amp-turns (and not current) and it is seen that at no-load, the field amp-turns required for rated no-load voltage are given by  $Oa$ . Under load conditions, the voltage will decrease due to demagnetising effect of armature reaction. This decrease can be made up by suitably increasing the field amp-turns. Let  $ac$  represent the equivalent demagnetising amp-turns per pole. Then, it means that in order to generate the same e.m.f. on load as at no-load, the field amp-turns/pole must be increased by an amount  $ac = bd$ . The point  $d$  lies on the curve  $LS$  which shows relation between the voltage  $E$  generated under **load** conditions and the field amp-turns. The curve  $LS$  is practically parallel to curve  $Ob$ . The terminal voltage  $V$  will be less than this generated voltage  $E$  by an amount  $= I_a R_a$  where  $R_a$  is the resistance of the armature circuit. From point  $d$ , a vertical line  $de = I_a R_a$  is drawn. The point  $e$  lies on the full-load saturation curve for the generator. Similarly, other points are obtained in the same manner and the full-load saturation curve  $Mp$  is drawn. The right-angled triangle  $bde$  is known as **drop reaction triangle**. Load saturation curve for half-load can be obtained by joining the mid-points of such lines as  $mn$  and  $bd$  etc. In the case of self-excited generators, load saturation curves are obtained in a similar way.

**(b) Internal and External Characteristics**

Let us consider a separately-excited generator giving its rated no-load voltage of  $E_0$  for a certain constant field current. If there were no armature reaction and armature voltage drop, then this voltage would have remained constant as shown in Fig. 28.3. by the dotted horizontal line  $I$ . But when the generator is loaded, the voltage falls due to these two causes, thereby giving slightly dropping characteristics. If we subtract from  $E_0$  the values of voltage drops due to armature reaction for different loads, then we get the value of  $E$ —the e.m.f. **actually** induced in the armature under load conditions. Curve  $II$  is plotted in this way and is known as the **internal characteristic**. The straight line  $Oa$  represents the  $I_a R_a$  drops corresponding to different armature currents. If we subtract from  $E$  the armature drop  $I_a R_a$ , we get terminal voltage  $V$ . Curve  $III$  represents the external characteristic and is obtained by subtracting ordinates the line  $Oa$  from those of curve  $II$ .

### 28.3. No-load Curve for Self-excited Generator

The *O.C.C.* or no-load saturated curves for self-excited generators whether shunt or series-connected, are obtained in a similar way.

Fig. 28.4

Fig. 28.5

The field winding of the

generator (whether *shunt* or *series* wound) is disconnected from the machine and connected to an external source of direct current as shown in Fig. 28.4. The field or exciting current  $I_f$  is varied rheostatically and its value read on the ammeter *A*. The machine is driven at constant speed by the prime mover and the generated e.m.f. on no-load is measured by the voltmeter connected across the armature.  $I_f$  is increased by suitable steps (starting from zero) and the corresponding values of  $E_o$  are measured. On plotting the relation between  $I_f$  and  $E_o$ , a curve of this form shown in Fig. 28.5 is obtained.

Self Excited Generator

Due to residual magnetism in the poles, some e.m.f. (=  $OA$ ) is generated even when  $I_f = 0$ . Hence, the curve starts a little way up. The slight curvature at the lower end is due to magnetic inertia. It is seen that the first part of the curve is practically straight. This is due to the fact that at low flux densities, reluctance of iron path being negligible (due to high permeability), total reluctance is given by the air-gap reluctance which is constant. Hence, the flux and consequently, the generated e.m.f. is directly proportional to the exciting current. However, at high flux densities, where  $\mu$  is small, iron path

reluctance becomes appreciable and straight relation between  $E$  and  $I_f$  no longer holds good. In other words, after point *B*, saturation of poles starts. However, the initial slope of the curve is determined by air-gap width.

It should be noted that *O.C.C.* for a higher speed would lie above this curve and for a lower speed, would lie below it.

It should also be noted and the load-saturation curve for a shunt generator is similar to the one shown in Fig. 28.2.

#### Critical Resistance for Shunt Generator

Now, connect the field windings back to the armature and run the machine as a shunt generator. Due to residual magnetism in the poles, some e.m.f. and hence current, would be generated. This current while passing through the field coils will strengthen the magnetism of the poles (provided field coils are properly connected as regards polarity). This will increase the pole flux which will further increase the generated e.m.f. Increased e.m.f. means more current which further increases the flux and so on. This mutual reinforcement of e.m.f. and flux proceeds on till equilibrium is reached at some point like *P* (Fig. 28.6). The point lies on the resistance line *OA* of the field winding. Let  $R$  be the resistance of the field winding. Line *OA* is drawn such that its slope equals the field winding

resistance *i.e.* every point on this curve is such that volt/ampere =  $R$ .

The voltage  $OL$  corresponding to point  $P$  represents the maximum voltage to which the machine will build up with  $R$  as field resistance.  $OB$  represents smaller resistance and the corresponding voltage  $OM$  is slightly greater than  $OL$ . If field resistance is increased, then slope of the resistance line increased, and hence the maximum voltage to which the generator will build up at a given speed, decreases. If  $R$  is increased so much that the resistance line does not cut the *O.C.C.* at all (like  $OT$ ), then obviously the machine will fail to excite *i.e.* there will be no 'build up' of the voltage. If the resistance line just lies along the slope, then with that value of field resistance, the machine will *just* excite. The value of the resistance represented by the tangent to the curve, is known as **critical resistance**  $R_c$  for a *given speed*.

Fig. 28.6

**28.4 How to Find Critical Resistance  $R_c$  ?**

First, *O.C.C.* is plotted from the given data. Then, tangent is drawn to its initial portion. The slope of this curve gives the critical resistance for the speed at which the data was obtained.

**28.5 How to Draw *O.C.C.* at Different Speeds ?**

Suppose we are given the data for *O.C.C.* of a generator run at a fixed speed, say,  $N_1$ . It will be shown that *O.C.C.* at any other constant speed  $N_2$  can be deduced from the *O.C.C.* for  $N_1$ . In Fig. 28.7 the *O.C.C.* for speed  $N_1$  is shown.

Fig. 28.7

Fig. 28.8

Since  $E \propto N$  for any fixed excitation, hence  $\frac{E_2}{E_1} = \frac{N_2}{N_1}$  or  $E_2 = E_1 \times \frac{N_2}{N_1}$

As seen, for  $I_f = OH$ ,  $E_1 = HC$ . The value of new voltage for the same  $I_f$  but at  $N_2$

$$E_2 = HC \times \frac{N_2}{N_1} = HD$$

In this way, point  $D$  is located. In a similar way, other such points can be found and the new *O.C.C.* at  $N_2$  drawn.

28.6. Critical Speed  $N_c$

Critical speed of a shunt generator is that speed for which the given shunt field resistance represents critical resistance. In Fig. 28.8, curve 2 corresponds to critical speed because  $R_{sh}$  line is tangential to it. Obviously

$$\frac{BC}{AC} = \frac{N_c}{\text{Full Speed}} = \frac{N_c}{N} \therefore N_c = \frac{BC}{AC} \times \text{Full speed } N$$

**Example 28.1.** The magnetization curve of a d.c. shunt generator at 1500 r.p.m. is :

$I_f$ (A) :	0	0.4	0.8	1.2	1.6	2.0	2.4	2.8	3.0
$E_0$ (V) :	6	60	120	172.5	202.5	221	231	237	240

For this generator find (i) no load e.m.f. for a total shunt field resistance of  $100 \Omega$  (ii) the critical field resistance at 1500 r.p.m. and (iii) the magnetization curve at 1200 r.p.m. and therefrom the open-circuit voltage for a field resistance of  $100 \Omega$ .

(b) A long shunt, compound generator fitted with interpoles is cumulatively-compounded. With the supply terminals unchanged, the machine is now run as compound motor. Is the motor differentially or cumulatively compounded ? Explain. (Elect, Machines, A.M.I.E. Sec. B, 1990)

**Solution.** The magnetisation curve at 1500 r.p.m. is plotted in Fig. 28.9 from the given data. The  $100 \Omega$  resistance line  $OA$  is obtained by joining the origin (0, 0) with the point (1A, 100 V). The voltage corresponding to point A is 227.5 V. Hence, no-load voltage to which the generator will build-up is 227.5 V.

The tangent  $OT$  represents the critical resistance at 1500 r.p.m. considering point B,  $R_c = 225/1.5 = 150 \Omega$ .

For 1200 r.p.m., the induced voltages for different field currents would be  $(1200/1500) = 0.8$  of those for 1500 r.p.m. The values of these voltages are tabulated below :

$I_f$ (A) :	0	0.4	0.8	1.2	1.6	2.0	2.4	2.8	3.0
$E_0$ (V) :	4.8	48	96	138	162	176.8	184.8	189.6	192

The new magnetisation curve is also plotted in Fig. 28.9. The  $100 \Omega$  line cuts the curve at point C which corresponds to an induced voltage of 166 V.

**Example 28.2.** A shunt generator is to be converted into a level compounded generator by the addition of a series field winding. From a test on the machine with shunt excitation only, it is found that the shunt current is 3.1 A to give 400 V on no load and 4.8 A to give the same voltage when the machine is supplying its full load of 200 A. The shunt winding has 1200 turns per pole. Find the number of series turns required per pole. (Elect. Machines, A.M.I.E. Sec. B, 1989)

Fig. 28.9

**Solution.** At no-load the ampere turns required to produce 400 V =  $3.1 \times 1200 = 3720$   
 On full-load ampere turns required to produce the same voltage =  $4.8 \times 1200 = 5760$   
 Additional ampere turns required due to de-magnetising effect of load current =  $5760 - 3720 = 2040$ .

If  $N$  is a number of series turns required when load current is 200 A, then  
 $N \times 200 = 2040, N = 10.2$

**Example 28.3.** The open-circuit characteristic of a d.c. shunt generator driven at rated speed is as follows :

Field Amperes :	0.5	1.0	1.5	2.0	2.5	3.0	3.5 A
Induced Voltage :	60	120	138	145	149	151	152 V

If resistance of field circuit is adjusted to  $53 \Omega$ , calculate the open circuit voltage and load current when the terminal voltage is 100 V. Neglect armature reaction and assume an armature resistance of  $0.1 \Omega$ .  
**(Electrical Technology Punjab Univ. Dec. 1989)**

**Solution.** Take  $I_f = 3 \text{ A}, R_{sh} = 53 \Omega$ ,

Point A is (3A, 159V) point. Line OA is the  $53 \Omega$  line in Fig. 28.10. It cuts drop =  $3 \times 53 = 159 \text{ V}$ . O.C.C. at B. Line BM is drawn parallel to the base. OM represents the O.C. voltage which equals **150 V**.

Fig. 28.10

Now, when  $V = 100 \text{ V}, I_{sh} = I_f = 100/53 = 1.89 \text{ A}$   
 Generated or O.C. voltage corresponding to this exciting current as seen from graph of Fig. 26.10 is 144 V.

Now  $E = V + I_a R_a$  or  $I_a R_a = 144 - 100 = 44 \text{ V}$   
 $\therefore 0.1 I_a = 44$  or  $I_a = 44/0.1 = 440 \text{ A}$

**Example 28.4.** The following figures give the O.C.C. of a d.c. shunt generator at 300 r.p.m.

Field amperes :	0	2	3	4	5	6	7
Armature volt :	7.5	92	132	162	183	190	212

Plot the O.C.C. for 375 r.p.m. and determine the voltage to which the machine will excite if field circuit resistance is  $40\ \Omega$ .

(a) What additional resistance would have to be inserted in the field circuit to reduce the voltage to 200 volts at 375 r.p.m.?

(b) Without this additional resistance, determine the load current supplied by the generator, when its terminal voltage is 200 V. Ignore armature reaction and assume speed to be constant. Armature resistance is  $0.4\ \Omega$ .  
(Elect. Machines - I, South Gujarat Univ. 1986)

**Solution.** The e.m.f. induced at 375 r.p.m. would be increased in the ratio 375/300 corresponding to different shunt field current values. A new table is given with the voltages multiplied by the above ratio.

Field amperes :	0	2	3	4	5	6	7
Armature volt :	9.4	115	165	202.5	228.8	248.8	265

The new O.C.C. at 375 r.p.m. is shown in Fig. 26.11. Line OA represents  $40\text{-}\Omega$  line.

The voltage corresponding to point A is 260 V. Hence machine will excite to 260 volt with  $40\ \Omega$  shunt field resistance.

(a) From Fig. 28.11, it is clear that for exciting the generator to 200 V, exciting current should be 3.8 A.

$$\therefore \text{Field circuit resistance} = 200/3.8 = 52.6\ \Omega$$

$$\therefore \text{Additional resistance required} = 52.6 - 40 = 12.6\ \Omega$$

(b) In this case, shunt field resistance =  $40\ \Omega$  ... (as above)

Terminal voltage = 200 V  $\therefore$  Field current =  $200/40 = 5\ \text{A}$

Generated e.m.f. for exciting current of 5 A = 228.8 V

For a generator  $E = V + I_a R_a \therefore I_a R_a = E - V$  or  $0.4 I_a = 228.8 - 20 = 208.8$

$\therefore I_a = 208.8/0.4 = 522\ \text{A} \therefore \text{Load current } I = 522 - 5 = 517\ \text{A}$

Fig. 28.11

**Example 28.5.** The open-circuit characteristic of a separately-excited d.c. generator driven at 1000 r.p.m. is as follows :

Field current :	0.2	0.4	0.6	0.8	1.0	1.2	1.4	1.6
E.M.F. volts :	30.0	55.0	75.0	90.0	100.0	110.0	115.0	120.0

If the machine is connected as shunt generator and driven at 1,000 r.p.m. and has a field resistance of  $100\ \Omega$ , find (a) open-circuit voltage and exciting current (b) the critical resistance and (c) resistance to induce 115 volts on open circuit.

(Elect. Machines, Nagpur, Univ. 1993)

**Solution.** The O.C.C. has been plotted in Fig. 28.12. The shunt resistance line OA is drawn as usual.

(a) O.C. voltage = **100 V**; Exciting current = **1 A**

(b) Line OT is tangent to the initial part of the O.C.C. It represents critical resistance. As seen from point C, value of critical resistance is  $90/0.6 = 150\ \Omega$ .

Fig. 28.12

(c) Line *OB* represents shunt resistance for getting 115 V on open-circuit. Its resistance =  $115/1.4 = 82.1 \Omega$ .

**Example 28.6.** A d.c. generator has the following magnetisation characteristics.

Field current (A) :	1	2	3	4	5	6	7	8
Generated e.m.f. (V) :	23	45	67	85	100	112	121	126

If the generator is shunt excited, determine the load current.

- (a) when terminal p.d. is 120 V, the field resistance is  $15 \Omega$  at a speed of 600 r.p.m. And
- (b) when terminal p.d. is 144 V, the field resistance is  $18 \Omega$  at a speed of 700 r.p.m.

**Solution.** (a) When terminal p.d. = 120 V, then field current  $I_f = V/R_{sh} = 120/15 = 8 \text{ A}$

From the given data, it is seen that the generated e.m.f. = 126 V\*

Voltage drop =  $126 - 120 = 6 \text{ V}$

Since drop due to armature reaction is neglected, this represents the armature drop.

$\therefore I_a R_a = 6$  or  $I_a = 6/0.02 = 300 \text{ A}$  Load current =  $300 - 8 = 292 \text{ A}$

(b) The O.C. data at 700 r.p.m. can be obtained by multiplying the given values of generated e.m.f. by a factor of  $700/600 = 7/6$ . Hence, the new data is :

Field current (A) :	1	2	3	4	5	6	7	8
Generated e.m.f. (V) :	26.8	52.5	78.2	99.2	116.6	131	141	146

When  $V = 144 \text{ V}$  and  $R_{sh} = 18 \Omega$ , field current =  $144/18 = 8 \text{ A}$

From the given data, the corresponding generated e.m.f. is 146 V.

Voltage drop  $I_a R_a = 146 - 144 = 2 \text{ V}$

$\therefore I_a = 2/0.02 = 100 \text{ A}$   $\therefore$  Load current =  $100 - 8 = 92 \text{ A}$

**Example 28.7.** The O.C.C. of a d.c. generator driven at 400 rev/min is as follows :

Field current (A) :	2	3	4	5	6	7	8	9
Terminal volts :	110	155	186	212	230	246	260	271

\* We need not plot the O.C.C. in this particular case.

Find :

(a) voltage to which the machine will excite when run as a shunt generator at 400 rev/min with shunt field resistance equal to  $34 \Omega$ .

(b) resistance of shunt circuit to reduce the O.C. voltage to 220 V.

(c) critical value of the shunt field circuit resistance.

(d) the critical speed when the field circuit resistance is  $34 \Omega$ .

(e) lowest possible speed at which an O.C. voltage of 225 V can be obtained.

(Electrical Technology, Bombay Univ. 1987)

**Solution.** The O.C.C. as plotted from the given data is shown in Fig. 28.13. The  $34\text{-}\Omega$  line  $OA$  is drawn as usual.

(a) The voltage to which machine will excite =  $OM = 255 \text{ V}$ .

(b) The horizontal line from  $N$  (220 V) is drawn which cuts the O.C.C. at point  $B$ . Resistance represented by line  $OB = 220/5.4 = 40.7 \Omega$ .

(c) Line  $OC$  has been drawn which is tangential at the origin to the O.C.C. This represents the value of critical resistance =  $140/2.25 = 62.2 \Omega$ .

(d) Take any convenient point  $D$  and erect a perpendicular which cuts both  $OA$  and  $OC$ .

$$\frac{DE}{DF} = \frac{N_C}{400} \quad \text{or} \quad \frac{110}{202} = \frac{N_C}{202}, \quad N_C = 218 \text{ r.p.m.}$$

(e) From point  $P$  (225 V) draw a horizontal line cutting  $OA$  at point  $G$ . From  $G$ , draw a perpendicular line  $GK$  cutting the O.C.C. at point  $H$ . If  $N'$  is the lowest speed possible for getting 225 volt with  $34 \Omega$  shunt circuit resistance, then

$$\frac{GK}{HK} = \frac{N'}{400} \quad \text{or} \quad \frac{225}{241} \text{ or } N' = 375 \text{ r.p.m.}$$

Fig. 28.13

**Example 28.8.** The magnetization characteristic for a 4-pole, 110-V, 1000 r.p.m. shunt generator is as follows :

Field current	0	0.5	1	1.5	2	2.5	3 A
O.C. voltage	5	50	85	102	112	116	120 V

Armature is lap-connected with 144 conductors. Field resistance is 45 ohms. Determine

- (i) voltage the machine will build up at no-load.
- (ii) the critical resistance.
- (iii) the speed at which the machine just fails to excite.
- (iv) residual flux per pole.

(Electrical Machinery- I, Mysore Unit. 1988)

**Solution.** In Fig. 28.14, OA represents the 45-Ω line which is drawn as usual.

(i) The voltage to which machine will build up = OM = **118 V**.

(ii) OT is tangent to the initial part of the O.C.C. It represents critical resistance. Take point B lying on this line. Voltage and exciting current corresponding to this point are 110 V and 1.1 A respectively.

$$\therefore R_c = 110/1.1 = \mathbf{100 \Omega}$$

(iii) From any point on OT, say point B, drop the perpendicular BD on X-axis.

$$\frac{CD}{BD} = \frac{N_c}{1000} \text{ or } \frac{49}{110} = \frac{N_c}{1000}$$

$$\therefore N_c = \mathbf{445 \text{ r.p.m.}}$$

(iv) As given in the table, induced e.m.f. due to residual flux (i.e. when there is no exciting current) is 5 V.

$$\therefore 5 = \frac{\Phi \times 144 \times 1000}{60} \left(\frac{4}{4}\right) \therefore \Phi = \mathbf{2.08 \text{ mWb.}}$$

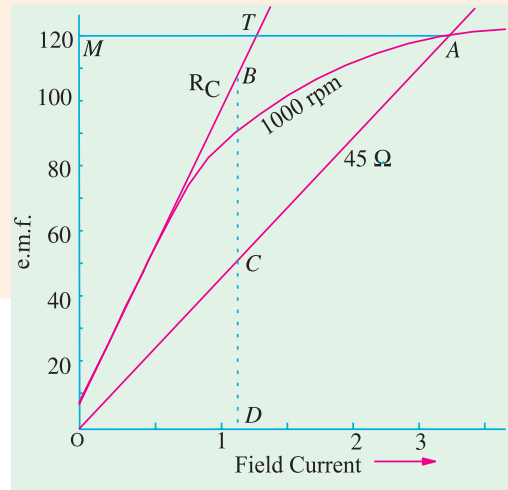

Fig. 28.14

**Example 28.9.** A shunt generator gave the following results in the O.C.C. test at a speed of r.p.m.

Field current (A) :	1	2	3	4	6	8	10
E.M.F. (volt) :	90	185	251	290	324	345	360

The field resistance is adjusted to 50 Ω and the terminal is 300 V on load. Armature resistance is 0.1 Ω and assuming that the flux is reduced by 5% due to armature reaction, find the load supplied by the generator. (Electromechanic, Allahabad Univ.; 1992)

**Solution.** When the terminal voltage is 300 V and  $R_{sh} = 50 \Omega$ , then field current is =  $300/40 = 6 \text{ A}$

With this shunt current, the induced e.m.f. as seen from the given table (we need not draw the O.C.C.) is 324 V.

Due to armature reaction, the flux and hence the induced e.m.f. is reduced to 0.95 of its no-load value.

Hence, induced e.m.f. when generator is no load =  $324 \times 0.95 = 307.8 \text{ V}$

Armature drop at the given load =  $307.8 - 300 = 7.8 \text{ V}$

$$I_a R_a = 7.8, \quad I_a = 7.8/0.1 = 78 \text{ A}$$

Load current =  $78 - 6 = 72 \text{ A}$ ; Generator output =  $72 \times 300/1000 = 21.6 \text{ kW}$

**Example 28.10.** A shunt generator gave the following open-circuit characteristic :

Field current :	0.5	1.0	1.5	2.0	2.5	3.0	3.5 A
O.C. e.m.f. :	54	107	152	185	210	230	245 V

The armature and field resistances are  $0.1 \Omega$  and  $80 \Omega$  respectively. Calculate (a) the voltage to which the machine will excite when run as a shunt generator at the same speed.

(b) The volts lost due to armature reaction when 100 A are passing in the armature at a terminal voltage of 175 V.

(c) The percentage reduction in speed for the machine to fail to excite on open circuit.

(Electrical Machines-I, Bombay Univ. 1988)

**Solution.** (a) O.C.C. is shown in Fig. 28.15. OA represents  $80 \Omega$  line. The maximum voltage to which the generator will build up is given by  $OM = 222 \text{ V}$ .

(b) With 175 V terminal p.d. on load

$$I_{sh} = 175/80 = 2.2 \text{ A}$$

Voltage corresponding to this field current is given by  $OC = 195 \text{ V}$ .

Voltage lost due to armature reaction and armature drop =  $195 - 175 = 20 \text{ V}$ .

Now, armature drop =  $0.1 \times 100 = 10 \text{ V}$

Let 'x' be the volts lost due to armature reaction.

Then  $10 + x = 20 \quad \therefore x = 10 \text{ V}$

(c) Line OT is drawn tangential to the curve. DFG is perpendicular to the base line.

$$\frac{N_c}{N} = \frac{FG}{DG} = \frac{160}{220} \quad \text{or} \quad \frac{N_e - N}{N} = \frac{-60}{220}$$

Percentage reduction in speed =  $\frac{-60}{220} \times 100 = -27.3 \%$

Fig. 28.15

**Example 28.11.** The O.C.C. of a shunt generator running at 800 r.p.m. is as follows :

Field current (amp.) :	1	2	3	4	5	6
Induced e.m.f. (volt).	82.5	180	225	252	273	282

If the shunt field resistance is  $60 \Omega$ , find

(i) the voltage to which the machine will build up running at the same speed (ii) the value of field regulating resistance if the machine is to build up to 120 V when its field coils are grouped in two parallel circuits and generator is running at half the speed.

(Electrical Technology, Hyderabad Univ. 1991)

**Solution.** O.C.C. is drawn from the given data and is shown in Fig. 28.16. OA represents  $60 \Omega$ . The voltage corresponding to point A is  $OM = 260 \text{ V}$ .

(i) Generator will build up to **260 volts**.

(ii) Lower curve represents the induced e.m.f. for different exciting current values at 400 r.p.m. From point B which represents 120 V, draw BC. From C draw a perpendicular CD which gives the

exciting current of 3.6 A. It means that current through *each* parallel path of shunt field coils is 3.6 A. Total current which passes through the field regulator resistance is  $3.6 \times 2 = 7.2$  A because it is in series with the field coils.

Hence, total shunt field resistance =  $120/7.2 = 16.67 \Omega$

Now, resistance of each shunt parallel path =  $60/2 = 30 \Omega$

Joint resistance of two parallel paths =  $30/2 = 15 \Omega$

$\therefore$  Shunt field regulator resistance =  $16.67 - 15 = 1.67 \Omega$

Fig. 28.16

**28.7. Voltage Build up of a Shunt Generator**

Before loading a shunt generator, it is allowed to build up its voltage. Usually, there is always present some residual magnetism in the poles, hence a small e.m.f. is produced initially.

This e.m.f. circulates a small current in the field circuit which increases the pole flux (provided field circuit is properly connected to armature, otherwise this current may wipe off the residual magnetism). When flux is increased, generated e.m.f. is increased which further increases the flux and so on. As shown in Fig. 28.17, *Oa* is the induced e.m.f. due to residual magnetism which appears across the field circuit and causes a field current *Ob* to flow. This current aids residual flux and hence produces, a larger induced e.m.f. *Oc*. In turn, this increased e.m.f. *Oc* causes an even larger current *Od* which creates more flux for a still larger e.m.f. and so on.

Now, the generated e.m.f. in the armature has

(a) to supply the ohmic drop  $I_f R_{sh}$  in the winding and (b) to overcome the opposing self-induced e.m.f. in the field coil *i.e.*  $L \cdot (dI_f/dt)$  because field coils have appreciable self-inductance.

$$e_g = I_f R_{sh} + L \cdot dI_f/dt$$

If (and so long as), the generated e.m.f. is in excess of the ohmic drop  $I_f R_{sh}$ , energy would continue being stored in the pole fields. For example, as shown in Fig. 28.17, corresponding to field current *OA*, the generated e.m.f. is *AC*.

Out of this, *AB* goes to supply ohmic drop  $I_f R_{sh}$  and *BC* goes to overcome self-induced e.m.f. in the coil. Corresponding to  $I_f = OF$ , whole of the generated e.m.f. is used to overcome the ohmic drop. None is left to overcome  $L \cdot dI_f/dt$ . Hence no energy is stored in the pole fields. Consequently, there is no further increase in pole flux and the generated e.m.f. With the given shunt field resistance represented by line *OP*, the maximum voltage to which the machine will build up is *OE*. If resistance is decreased, it will build up to a somewhat higher voltage. *OR* represents the resistance known as **critical resistance**. If shunt field resistance is greater than this value, the generator will fail to excite.

Fig. 28.17

### 28.8. Conditions for Build-up of a Shunt Generator

We may summarize the conditions necessary for the build-up of a (self-excited) shunt generator as follows :

1. There must be some residual magnetism in the generator poles.

2. For the given direction of rotation, the shunt field coils should be correctly connected to the armature *i.e.* they should be so connected that the induced current reinforces the e.m.f. produced initially due to residual magnetism.

3. If excited on open circuit, its shunt field resistance should be less than the critical resistance (which can be found from its O.C.C.)

4. If excited on load, then its shunt field resistance should be more than a certain minimum value of resistance which is given by internal characteristic (Art 28.11).

Fig. 28.18

### 28.9. Other Factors Affecting Voltage Building of a DC Generator

In addition to the factors mentioned above, there are some other factors which affect the voltage building of a self-excited d.c. generator. These factors are (i) reversed shunt field connection (ii) reversed rotation and (iii) reversed residual magnetism. These adverse effects would be explained with the help of Fig. 28.18 and the right-hand rule for finding the direction of the coil flux. For the sake of simplicity, only one field pole has been shown in the Fig. 28.18.

Fig. 28.18 (a) represents the normal operation, the prime mover rotation is clockwise and both the residual flux  $\Phi_R$  and the field flux  $\Phi_F$  are directed to the left.

Fig. 28.18 (b) shows reversed connection of the field circuit which causes  $\Phi_F$  to oppose  $\Phi_R$ . Consequently, the generator voltage builds down from its original residual value.

In Fig. 28.18 (c), reversed armature rotation causes the reversal of the voltage produced by the residual magnetism. Even though the field coil connections are correct, the reversed field current flow causes  $\Phi_F$  to oppose  $\Phi_R$  so that the voltage builds down from its original residual value.

Fig. 28.18 (d) shows the case when due to some reason the residual magnetism gets reversed. Hence, the armature voltage is also reversed which further reverses the field current. Consequently, both  $\Phi_F$  and  $\Phi_R$  are reversed but are directed to the right as shown. Under this condition, the voltage buildup is in the reversed direction. Obviously, the generator will operate at rated voltage but with reversed polarity.

If desired, the reversed polarity can be corrected by using an external d.c. source to remagnetise the field poles in the correct direction. This procedure is known as field flashing.

**Example 28.12.** The O.C.C. of a generator is given by the following :

Field current :	1.5	3.5	4.5	6	7.5	9	10.5
E.M.F. :	168	330	450	490	600	645	675

The speed at which data is obtained is 1000 r.p.m. Find the value of the shunt field resistance that will give a p.d. of 600 V with an armature current of 300 A at the same speed. Due to armature

reaction, the shunt field current is given by  $I_{sh}(\text{eff.}) = I_{sh} - 0.003 I_a$ . Armature resistance, including brush contact resistance, is  $0.1 \Omega$ . What will be the p.d. on open circuit at the same speed?

**Solution.** As shown in Fig. 28.19, the O.C.C. has been plotted from the given data.

Voltage drop due to armature resistance =  $300 \times 0.1 = 30 \text{ V}$ .

Reduction of field current due to armature reaction =  $0.003 \times 300 = 0.9 \text{ A}$ .

Any point A is taken on the O.C.C. A vertical distance  $AB = 30 \text{ V}$  is taken and then the horizontal line  $BC = 0.9 \text{ A}$  is drawn thus completing triangle  $ABC$  which is known as drop reaction triangle. Then, point C lies on the 300 ampere load saturation curve. This curve can be drawn by finding such similar points like  $C'$  etc.

From point L representing 600 V, a horizontal line is drawn cutting the load saturation curve at D. Join OD. Current corresponding to point D is 9.4 A. The slope of  $I_f$  the line OD gives the value of shunt resistance to give 600 V with 300 amperes of armature current.

$$\therefore R_{sh} = 600/9.4 = 63.8 \Omega$$

It is seen that e.m.f. on open circuit is 678 V.

Fig. 28.19

### 28.10. External Characteristic

After becoming familiar with the no-load characteristic of a shunt generator, we will now proceed to find its external characteristic ( $V/I$ ) when loaded. It is found that if after building up, a shunt generator is loaded, then its terminal voltage  $V$  drops with increase in load current. Such a drop in voltage is undesirable especially when the generator is supplying current for light and power for which purpose it is desirable that  $V$  should remain practically constant and independent of the load. This condition of constant voltage is almost impossible to be fulfilled with a shunt generator unless the field current is being automatically adjusted by an automatic regulator. Without such regulation terminal voltage drops considerably as the load on the generator is increased. These are three main reasons for the drop in terminal voltage of a shunt generator when under load.

#### (i) Armature resistance drop :

As the load current increases, more and more voltage is consumed in the ohmic resistance of the armature circuit. Hence, the terminal voltage  $V = E - I_a R_a$  is decreased where  $E$  is the induced e.m.f. in the armature under load condition.

#### (ii) Armature reaction drop

Due to the demagnetising effect of armature reaction, pole flux is weakened and so the induced e.m.f. in the armature is decreased.

(iii) The drop in terminal voltage  $V$  due to (i) and (ii) results in a decreased field current  $I_f$  which further reduces the induced e.m.f.

For obtaining the relation between the terminal voltage and load current, the generator is connected as shown in Fig. 28.20 (a).

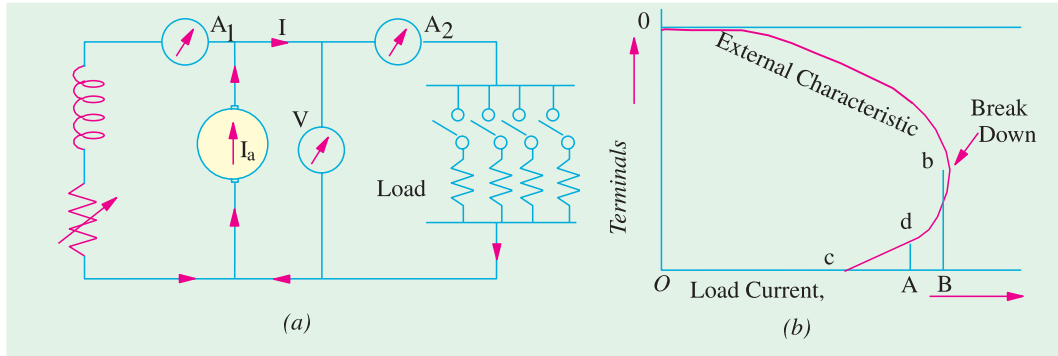

Fig. 28.20

The shunt generator is first excited on no-load so that it gives its full open circuit voltage =  $Oa$  [Fig. 28.20 (b)]. Then, the load is gradually applied and, at suitable intervals, the terminal voltage  $V$  (as read by the voltmeter) and the load current  $I$  (as read by the ammeter  $A_2$ ) are noted. The field current as recorded by ammeter  $A_1$  is kept constant by a rheostat (because during the test, due to heating, shunt field resistance is increased). By plotting these readings, the external characteristic of Fig. 28.20 (b) is obtained. The portion  $ab$  is the working part of this curve. Over this part, if the load resistance is decreased, load current is increased as usual, although this results in a comparatively small additional drop in voltage. These conditions hold good till point  $b$  is reached. This point is known as breakdown point. It is found that beyond this point (where load is maximum =  $OB$ ) **any effort to increase load current by further decreasing load resistance results in decreased load current (like  $OA$ ) due to a very rapid decrease in terminal voltage.**

We will discuss the reason for this unusual behaviour of the generator in more details. Over the earlier portion  $ab$  [Fig. 28.20 (b)] where the load current is comparatively small, when external load resistance is decreased, it results in increased load current as might be expected keeping Ohm's law in mind. It should not, however, be forgotten that due to increase in load current,  $V$  is also decreased somewhat due to the cause (iii) given above. But over the portion  $ab$ , the effect of decrease in load resistance predominates the effect of decrease in  $V$  because load current is relatively small.

At point  $b$ , generator is delivering a very large current *i.e.* current which is many times greater than its normal current. If load resistance is decreased at this point so as to be able to draw a load current greater than  $OB$ , the current is **increased** momentarily. But due to the severe armature reaction for this heavy current and increased  $I_a R_a$  drop, the terminal voltage  $V$  is drastically reduced. The effect of this drastic reduction in  $V$  results in less load current (=  $OA$ ). In other words, over the portion  $bdc$  of the curve, the terminal voltage  $V$  decreases more rapidly than the load resistance. Hence, any, further decrease in load resistance actually causes a **decrease** in load current (it may seem to contravene Ohm's law but this law is not applicable, here since  $V$  is not constant). As load resistance is decreased beyond point  $b$ , the curve turns back till when the generator is actually short-circuited, it cuts the current axis at point  $c$ . Here, terminal voltage  $V$  is reduced to zero, though there would be some value of  $E$  due to residual magnetism (Fig. 28.22).

### 28.11. Voltage Regulation

By voltage regulation of a generator is meant the change in its terminal voltage with the change in load current when it is running at a constant speed. If the change in voltage between no-load and full load is small, then the generator is said to have good regulation but if the change in voltage is large, then it has poor regulation. The **voltage regulation of a d.c. generator is the change in voltage when the load is reduced from rated value to zero, expressed as percentage of the rated load**

voltage.

If no-load voltage of a certain generator is 240 V and rated-load voltage is 220 V, then,  $\text{regn.} = (240 - 220)/220 = 0.091$  or 9.1 %

### 28.12. Internal or Total Characteristic

As defined before, internal characteristic gives the relation between  $E$  and  $I_a$ . Now in a shunt generator

Fig. 28.21

Fig. 28.22

Hence,  $E/I_a$  curve can be obtained from  $V/I$  curve as shown in Fig. 28.21. In this figure,  $ab$  represents the external characteristic as discussed above. The field resistance line  $OB$  is drawn as usual. The horizontal distances from  $OY$  line to the line  $OB$  give the values of field currents for different terminal voltages. If we add these distances horizontally to the external characteristic  $ab$ , then we get the curve for the total armature current *i.e.* dotted curve  $ac$ . For example, point  $d$  on  $ac$  is obtained by making  $gd = ef$ . The armature resistance drop line  $Or$  is then plotted as usual. If brush contact resistance is assumed constant, then armature voltage drop is proportional to the armature current. For any armature current =  $OK$ , armature voltage drop  $I_a R_a = mK$ . If we add these drops to the ordinates of curve  $ac$ , we get the internal characteristic. For example,  $St = mK$ . The point  $t$  lies on the internal characteristic. Other points like  $t$  can be found similarly at different armature currents as the total characteristic can be drawn.

It may be noted here, in passing, that product  $E I_a$  gives the total power developed within the armature. Some of this power goes to meet  $I^2 R$  losses in armature and shunt field windings and the rest appears as output.

As explained in Art 28.10 if load resistance is decreased, the armature current increases up to a certain load current value. After that, any decrease in load resistance is not accompanied by increase in load current. Rather, it is decreased and the curve turns back as shown in Fig. 28.22. If the load resistance is too small, then the generator is short-circuited and there is no generated e.m.f. due to heavy demagnetisation of main poles.

Line  $OP$  is tangential to the internal characteristic  $MB$  and its slope gives the value of the **minimum** resistance with which the generator will excite if excited **on load**.

28.13. Series Generator

In this generator, because field windings are in series with the armature [Fig. 28.23 (a)], they carry full armature current  $I_a$ . As  $I_a$  is increased, flux and hence generated e.m.f. is also increased as shown by the curve. Curve  $Oa$  is the *O.C.C.* The extra exciting current necessary to neutralize the weakening effect of armature reaction at full load is given by the horizontal distance  $ab$ . Hence, point  $b$  is on the internal characteristic. If the ordinate  $bc = gh =$  armature voltage drop, then point  $c$  lies on the external characteristic [Fig. 28.23 (b)].

It will be noticed that a series generator has rising voltage characteristic *i.e.* with increase in load, its voltage is also increased.

But it is seen that at high loads, the voltage starts decreasing due to excessive demagnetising effects of armature reaction. In fact, terminal voltage starts decreasing as load current is increased as shown by the dotted curve. For a load current  $OC'$ , the terminal voltage is reduced to zero as shown.

**Example 28.13.** In a 220 V supply system, a series generator, working on a linear portion of its magnetisation characteristic is employed as a booster.

The generator characteristic is such that induced e.m.f. increases by 1 volt for every increase of 6 amperes of load current through the generator. The total armature resistance of the generator is 0.02 Ω. If supply voltage remains constant, find the voltage supplied to the consumer at a load current of 96 A. Calculate also the power supplied by the booster itself.

Fig. 28.23

**Solution.**

- Voltage increase for 6 amperes = 1 V ∴ Voltage increase for 96 A = 96/6 = 16 V
- Voltage drop in series coils = 96 × 0.02 = 1.9 V
- Net Voltage rise due to booster = 16 – 1.9 = 14.1 V
- Voltage at consumer end = 220 + 14.1 = **234.1 V**
- Power supplied by booster itself = 14.1 × 96 = 1354 W = **1.354 kW**

**Example 28.14.** A d.c. series generator, having an external characteristic which is a straight line through zero to 50 V at 200 A is connected as a booster between a station bus bar and a feeder of 0.3 ohm resistance. Calculate the voltage difference between the station bus-bar and the far end of the feeder at a current of (i) 200 A and (ii) 50 A.

(AIME Sec. B Elect. Machine Summer 1991)

- Solution. (i)** Voltage drop = 200 × 0.3 = 60 V
- Booster voltage provided by series generator for 200 A current as given = 50 V.

$$\begin{aligned} \therefore \quad \text{Net voltage decrease} &= 60 - 50 = 10 \text{ V} \\ \text{(ii) Feeder drop} &= 50 \times 0.3 = 15 \text{ V} \\ \text{Booster voltage provided by series generator (by proportion) is} \\ &= 50 \times 50/200 = 12.5 \text{ V} \\ \therefore \quad \text{Net decrease in voltage} &= 15 - 12.5 = 2.5 \text{ V} \end{aligned}$$

### 28.14. Compound-wound Generator

A shunt generator is unsuitable where constancy of terminal voltage is essential, because its terminal voltage decreases as the load on it increases. This decrease in  $V$  is particularly objectionable for lighting circuit where even slight change in the voltage makes an appreciable change in the candle power of the incandescent lamps. A shunt generator may be made to supply substantially constant voltage (or even a rise in voltage as the load increases) by adding to it a few turns joined in series with either the armature or the load (Fig. 28.24). These turns are so connected as to aid to shunt turns when the generator supplies load. As the load current increases, the current through the series windings also increase thereby increasing the flux. Due to the increase in flux, induced e.m.f. is also increased. By adjusting the number of series turns (or series amp-turns), this increase in e.m.f. can be made to balance the combined voltage drop in the generator due to armature reaction and the armature drop. Hence,  $V$  remains practically constant which means that field current is also almost unchanged. We have already discussed the three causes which decrease the terminal voltage of a shunt generator (Art 28.10). Out of these three, the first two are neutralized by the series field amp-turns and the third one, therefore, does not occur.

If the series field amp-turns are such as to produce the same voltage at rated load as at no-load, then the generator is **flat-compounded**. It should be noted, however, that even in the case of a flat-compounded generator, the voltage is not constant from no-load to rated-load. At half the load, the voltage is actually greater than the rated voltage as seen from Fig. 28.24.

If the series field amp-turns are such that the rated-load voltage is greater than the no-load voltage, then generator is **over-compounded**. If rated-load voltage is less than the no-load voltage, then the generator is **under-compounded** but such generators are seldom used.

For short distances such as in hotels and office buildings, flat-compound generators are used because the loss of voltage over small lengths of the feeder is negligible. But when it is necessary to maintain a constant voltage then an over-compounded generator, which combines the functions of a generator and a booster, is invariably used.

Fig. 28.24

### 28.15. How to Calculate Required Series Turns ?

Consider a 110-V, 250-ampere generator. Suppose it gives its rated no-load voltage with a field current of 5.8 A. If, now, the series windings are disconnected and the shunt field rheostat is left unchanged then the machine will act as shunt generator, hence its voltage will fall with increase in load current. Further, supply that the field current has to be increased to 6.3 A in order to maintain the rated terminal voltage at full load. If the number of turns of the shunt field winding is 2000, then  $2000 \times (6.3 - 5.8) = 1000$  amp-turns represent the additional excitation that has to be supplied by the series windings. As series turns will be carrying a full load current of 250 A, hence number of series turns =  $1000/250 = 4$ .

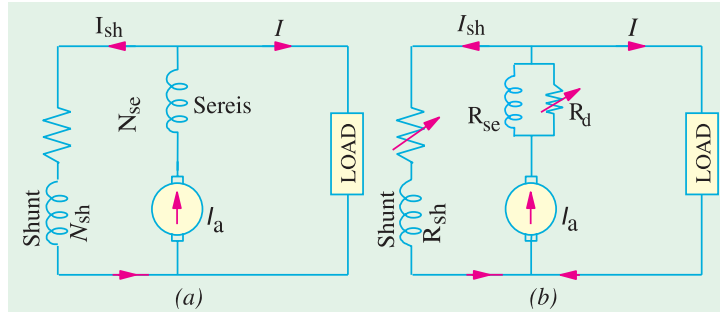

Fig. 28.25

In general, let

$\Delta I_{sh}$  = increase in shunt field current required to keep voltage constant from no-load to full-load

$N_{sh}$  = No. of shunt field turns per pole (or the total number of turns)

$N_{se}$  = No. of series turns per pole (or the total number of turns)

$I_{se}$  = current through series winding

= armature current  $I_a$  —for long-shunt

= load current  $I$  —for short-shunt

It is seen that while running as a simple generator, the increase in shunt field ampere-turns necessary for keeping its voltage constant from no-load to full-load is  $N_{sh} \cdot \Delta I_{sh}$ . This increase in field excitation can be alternatively achieved by adding a few series turns to the shunt generator [Fig. 28.25 (a)] thereby converting it into a compound generator.

$$\therefore N_{sh} \cdot \Delta I_{sh} = N_{se} I_{se}$$

If other things are known,  $N_{se}$  may be found from the above equation.

In practice, a few extra series amp-turns are taken in order to allow for the drop in armature. Any surplus amp-turns can be changed with the help of a diverter across the series winding as shown in Fig. 28.25 (b).

As said above, the degree of compounding can be adjusted with the help of a variable-resistance, diverter as shown in Fig. 28.25 (b). If  $I_d$  is the current through the diverter of resistance  $R_d$ , then remembering that series windings and diverter are in parallel,

$$\therefore I_{se} \cdot R_{se} = I_d R_d \quad \text{or} \quad R_d = I_{se} R_{se} / I_d$$

**Example 28.15.** A shunt generator is converted into a compound generator by addition of a series field winding. From the test on the machine with shunt excitation only, it is found that a field current of 5 A gives 440 V on no-load and that 6 A gives 440 V at full load current of 200 A. The shunt winding has 1600 turns per pole. Find the number of series turns required.

(Elect. Machines, A.M.I.E., Sec., B, 1991)

**Solution.** It would be assumed that shunt generator is converted into a short shunt compound generator. It is given that for keeping the voltage of shunt generator constant at 440 V both at no-load and full-load, shunt field ampere-turns per pole have to be increased from  $1600 \times 5 = 8000$  to

$(1600 \times 6) = 9600$  i.e. an increase of  $(9600 - 8000) = 1600$  AT. The same increase in field AT can be brought about by adding a few series turns.

Let  $n$  be the number of series turns required per pole. Since they carry 200 A,

$$\therefore n \times 200 = 1600; n = \mathbf{8 \text{ turns/pole}}$$

**Example 28.16.** A long shunt compound generator has a shunt field winding of 1000 turns per pole and series field winding of 4 turns per pole and resistance  $0.05 \Omega$ . In order to obtain the rated voltage both at no-load and full-load for operation as shunt generator, it is necessary to increase field current by 0.2 A. The full-load armature current of the compound generator is 80 A. Calculate the diverter resistance connected in parallel with series field to obtain flat compound operation.

(Elect. Machines A.M.I.E. Sec. B, 1993)

**Solution.**

Additional AT required to maintain rated voltage both at no-load and full-load (Fig. 28.26) =  $1000 \times 0.2 = 200$

No. of series turns/pole = 4

Current required to produce 200 AT by the series field =  $200/4 = 50$  A.

Since  $I_a = 80$  A, the balance of 30 A must pass through the parallel diverter resistance.

$$\therefore 30R = 50 \times 0.05, R = 0.0833 \Omega$$

Fig. 28.26

**Example 28.17.** A 220-V compound generator is supplying a load of 100 A at 220 V. The resistances of its armature, shunt and series windings are  $0.1 \Omega$ ,  $50 \Omega$  and  $0.06 \Omega$  respectively. Find the induced e.m.f. and the armature current when the machine is connected (a) short shunt (b) long shunt (c) how will the series amp-turns be changed in (b) if a diverter of  $0.14 \Omega$  is connected in parallel with the series windings? Neglect armature reaction and brush contact drop.

**Solution. (a) Short-shunt** (Fig. 28.27).

$$\text{Voltage drop in series} = 100 \times 0.06 = 6 \text{ V}; I_{sh} = 220/50 = 4.4 \text{ A.}$$

$$\therefore I_a = 100 + 4.4 = \mathbf{104.4}$$

$$\text{Armature drop} = 104.4 \times 0.1 = 10.4 \text{ V}$$

$$\therefore \text{Induced e.m.f.} = 220 + 6 + 10.5 = \mathbf{236.4 \text{ V}}$$

**(b) Long-shunt** (Fig. 28.28)

$$I_{sh} = 220/50 = 4.4 \text{ A} \quad \therefore I_a = 100 + 4.4 = \mathbf{104.4 \text{ A}}$$

Voltage drop over armature and series field winding =  $104.4 \times 0.16 = 16.7$  V

$$\therefore \text{Induced e.m.f.} = 200 + 16.7 = \mathbf{216.7 \text{ V}}$$

Fig. 28.27

Fig. 28.28

Fig. 28.29

(c) As shown in Fig. 28.29, a divertor of resistance  $0.14 \Omega$  is connected in parallel with the series field winding. Let  $n$  be the number of series turns.

Number of series amp-turns without divertor =  $n \times 104.4 = 104.4 n$

When divertor is applied, then current through series field is

$$= \frac{104.4 \times 0.14}{(0.14 + 0.06)} = 73.8 \text{ A}$$

$\therefore$  Series amp-turns =  $73.8 \times n$   $\therefore$  Series amp-turns are reduced to  $\frac{73.8 n}{104.4 n} \times 100 = 70 \%$

**Example 28.18.** A 250-kW, 240-V generator is to be compounded such that its voltage rises from 220 volts at no-load to 240 V at full load. When series field is cut out and shunt field is excited from an external source, then from the load test it is found that this rise in voltage can be obtained by increasing the exciting current from 7 A at no-load to 12 A at full-load. Given shunt turns/pole = 650, series turns/pole = 4 and resistance of series winding,  $0.006 \Omega$ . If the machine is connected long-shunt, find the resistance of the series amp-turns at no-load and drop in series winding resistance at full-load.

**Solution.** Full-load current =  $250 \times 10^3 / 240$   
= 1042 A

Increase in shunt field ampere-turns to over-compound the shunt generator

$$= 650 (12 - 7) = 3,250. \text{ As seen from Fig. 28.30}$$

$$4 \times I_{se} = 3250$$

$$I_{se} = 3250/4 = 812.5 \text{ A}$$

$$\therefore I_d = 1042 - 812.5 = 229.5 \text{ A}$$

It is so because no-load shunt current being negligible,  $I_a = I = 1042 \text{ A}$ .

Since series winding and divertor are in parallel,  $I_d R_d = I_{se} R_{se}$  or  $229.5 R_d = 812.5 \times 0.006$

$$\therefore R_d = 0.0212 \Omega$$

**Example 28.19.** A 60-kW d.c. shunt generator has 1600 turns/pole in its shunt winding. A shunt field current of 1.25 A is required to generate 125 V at no-load and 1.75 A to generate 150 V at full load. Calculate

(i) the minimum number of series turns/pole needed to produce the required no-load and full-load voltages as a short-shunt compound generator.

(ii) if the generator is equipped with 3 series turns/pole having a resistance of  $0.02 \Omega$ , calculate divertor resistance required to produce the desired compounding.

(iii) voltage regulation of the compound generator.

**Solution.** (i) Extra excitation ampere-turns required =  $1600 (1.75 - 1.25) = 800$

$$I_{se} = I = 60,000/150 = 400 \text{ A}$$

$$\therefore \text{No. of series turns/pole required} = 800/400 = 2$$

Hence, minimum number of series turns/pole required for producing the desired compound generator terminal voltage is 2.

(ii) Now, actual No. of series turns/pole is 3. Hence, current passing through it can be found from

$$3 \times I_{se} = 800; I_{se} = 800/3 \text{ A}$$

As shown in Fig. 28.31,  $I_d = 400 - (800/3) = 400/3 \text{ A}$

Also  $(800/3) \times 0.02 = (400/3) \times R_d$ ;  $R_d = 0.04 \Omega$

(iii) % regn. =  $(125 - 150) \times 100/150 = -16.7\%$

Fig. 28.30

Fig. 28.31

**Example 28.20.** A D.C. generator having an external characteristics which is a straight line through zero to 50 V at 200 Amp, is connected as a booster between a station bus-bar and a feeder of 0.3 ohm resistance. Calculate the voltage between the far end of the feeder and the bus-bar at a current of (i) 160 A, (ii) 50 A. (Manomaniam Surdaranar Univ. Nov. 1998)

**Solution.** Due to the feeder resistance of 0.3 ohm there is a voltage drop of  $1 \times 0.3$  volts in the direction of current, where  $I$  refers to the current flowing. Due to booster, there is a rise in voltage given by  $I \times (50/200)$  according to the  $V$ - $I$  characteristic given for the series generator. As a sum total of these two, the net feeder drop will be  $I \times (0.3 - 0.25)$  or  $I$  volts, and that represents the voltage between far end of the feeder and the bus-bar.

(i) At 160 A, the net voltage drop in feeder =  $160 \times 0.05$  or  $48 - 40 = 9$  volts.

Since 48 volts drop is partially compensated by 40 volts boosted up.

(ii) At 50 A, the required answer = (15 volts drop 12.5 volts boosted up) = 2.5 volts drop.

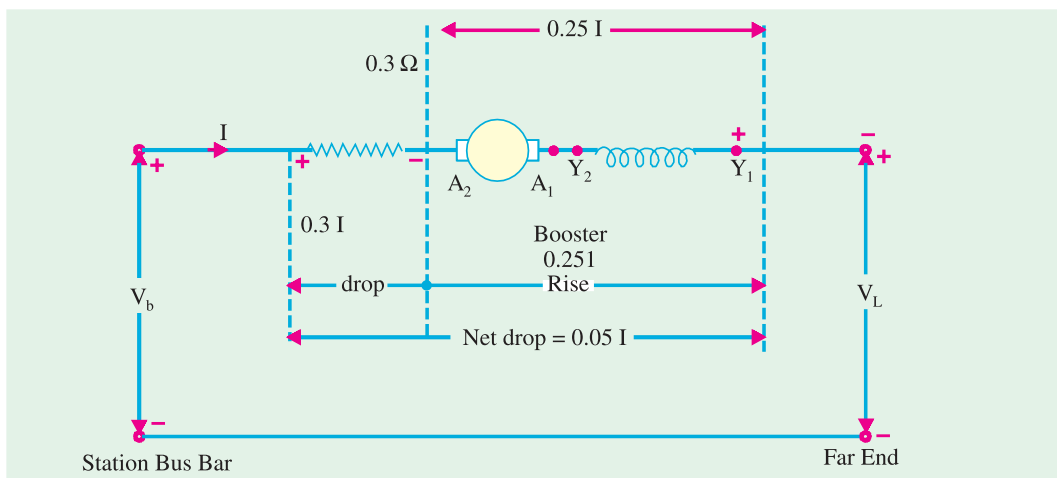

Fig. 28.32. Feeder and Booster

### 28.16. Uses of D.C. Generators

1. **Shunt generators** with field regulators are used for ordinary lighting and power supply purposes. They are also used for charging batteries because their terminal voltages are almost constant or can be kept constant.

2. **Series generators** are not used for power supply because of their rising characteristics. However, their rising characteristic makes them suitable for being used as boosters (Ex. 28.15) in certain types of distribution systems particularly in railway service.

#### 3. Compound generators

The cumulatively-compound generator is the most widely used d.c. generator because its external characteristic can be adjusted for compensating the voltage drop in the line resistance. Hence, such generators are used for motor driving which require d.c. supply at constant voltage, for lamp loads and for heavy power service such as electric railways.

The differential-compound generator has an external characteristic similar to that of a shunt generator but with large demagnetization armature reaction. Hence, it is widely used in arc welding where larger voltage drop is desirable with increase in current.

Compound generators are used in electric railways

## Tutorial Problem in 28.1

1. The *OC* curve of a d.c. shunt generator for a speed of 1000 r.p.m. is given by the following table.

<i>Field current</i> :	2.0	3.0	4.0	5.0	6.0	7.0
<i>E.M.F. volts</i> :	102	150	188	215	232	245

The shunt has a resistance of  $37 \Omega$ . Find the speed at which excitation may be expected to build up.

The armature resistance of  $0.04 \Omega$ . Neglecting the effects of brush drop and armature reaction, estimate the p.d. when the speed is 1000 r.p.m. and the armature delivers a current of 100 A. **(725 r.p.m.; 231 V)**

2. A d.c. shunt generator running at 850 r.p.m. gave the following *O.C.C.* data :

<i>Field current (A)</i> :	0	0.5	1	2	3	4	5
<i>E.M.F. (V)</i> :	10	60	120	199	232	248	258

If the resistance of the shunt field is  $50 \Omega$ , determine the additional resistance required in the shunt field circuit to give 240 V at a speed of 1000 r.p.m. **[64.3  $\Omega$ ]**

3. Sketch the load characteristic of a d.c. generator with (i) shunt (ii) series excitation. Give reasons for the particular shape in each case.

The *O.C.C.* at 700 r.p.m. of a series generator with separately-excited field is as follows :

<i>Field current (A)</i> :	20	40	50	60	75
<i>Armature e.m.f. (V)</i> :	190	360	410	450	480

Determine the current and terminal voltage as a self-excited series machine when running at 600 r.p.m. with a load of  $6 \Omega$  connected to the terminal. Resistance of armature and series winding is  $0.3 \Omega$ . Ignore effect of armature reaction. **[369 V; 61.5 A]**

4. The *O.C.C.* data for separately-excited generator when run at 130 r.p.m. on open circuit is

<i>E.M.F. (V)</i> :	12	44	73	98	113	122	127
<i>Exciting current</i> :	0	0.2	0.4	0.6	0.8	1.0	1.2

Deduce the curve of e.m.f. and excitation when the generator is running separately-excited at 1000 r.p.m. To what voltage will the generator build up on no-load when running at 1000 r.p.m.? To what voltage will the generator build up on no-load when running at 100 r.p.m. if the total field resistance is  $100 \Omega$ ? **[91 V]**

5. The following figures give the *O.C.C.* of d.c. Shunt generator driven at a constant speed of 700 r.p.m.

<i>Terminal voltage (V):</i>	10	20	40	80	120	160	200	240	260
<i>Field Current (A)</i> :	0	0.1	0.24	0.5	0.77	1.2	1.92	3.43	5.2

Determine the critical resistance at (a) 700 r.p.m. (b) 850 r.p.m. If resistance of field coils is  $50 \Omega$ , find the range of the field rheostat required to vary the voltage between the limits of 180 V and 250 V on open circuit at a speed of 700 r.p.m. **[160  $\Omega$  ; 194  $\Omega$ ; 70  $\Omega$  to 10  $\Omega$ ]**

6. The *O.C.C.* of a shunt generator when separately-excited and running at 1000 r.p.m. is given by :

<i>O.C.C. volt</i> :	56	112	150	180	200	216	230
<i>Field amp.</i> :	0.5	1.0	1.5	2.0	2.5	3.0	3.5

If the generator is shunt-connected and runs at 1100 r.p.m. with a total field resistance of  $80 \Omega$ , determine (a) no-load e.m.f.

(b) the output when the terminal voltage is 200 V if the armature resistance is  $0.1 \Omega$ .

(c) the terminal voltage of the generator when giving the maximum output current.

Neglect the effect of armature reaction and of brush contact drop.

**[236 V; 200 V; 460 V; 150 V (approx.)]**

7. A long-shunt compound d.c. generator with armature, series field and shunt field resistance of 0.5, 0.4 and  $250 \Omega$  respectively gave the following readings when run at constant speed :

<i>Load current (A)</i> :	0	10	20	30	40
<i>Terminal p.d. (V)</i> :	480	478	475	471	467

Plot the curve of internal generated e.m.f. against load current. Explain fully the steps by which this curve is obtained and tabulate the values from which it is plotted. **[For 40 A; E = 504.7 V (approx.)]**

8. A shunt generator has the following open-circuit characteristic at 800 r.p.m.

Field amperes	:	0.5	1.0	1.5	2.0	2.5	3.0	3.5
E.M.F. Volt	:	54	107	152	185	210	230	245

Armature and shunt field resistances are respectively  $0.1 \Omega$  and  $80 \Omega$ . The terminal p.d. falls to 175 V when the armature current is 100 A. Find the O.C. volts and the volts lost due to (i) reduction in the field current (ii) armature resistance (iii) armature reaction. **[220 V (i) 27 V (ii) 120 V (iii) 8 V]**

9. The open-circuit characteristic of a shunt generator when driven at normal speed is as follows :

Field current	:	0.5	1.0	1.5	2.0	2.5	3.0	3.5 A
O.C. volts	:	54	107	152	185	210	230	240 V

The resistance of armature circuit is  $0.1 \Omega$ . Due to armature reaction the effective field current is given by the relation  $I_{sh}(\text{eff.}) = I_{sh} - 0.003 I_a$ . Find the shunt field circuit resistance that will give a terminal voltage of 220 V with normal speed (a) on open circuit (b) at a load current of 100 A. Also find (c) number of series turns for level compounding at 220 V with 100 A armature current ; take number of shunt turns per pole as 1200 and (d) No. of series turns for over-compounding giving a terminal voltage of 220 V at no-load and 230 V with 100 A armature current. **[(a)  $80 \Omega$  (b)  $66 \Omega$  (c)  $6.8 \Omega$  (d) 9.1 turns]**

10. Find how many series turns per pole are needed on a 500-kW compound generator required to give 450 V on no-load and 500 V on full-load, the requisite number of ampere-turns per pole being 9,000 and 6,500 respectively. The shunt winding is designed to give 450 V at no-load when its temperature is  $20^\circ\text{C}$ . The final temperature is  $60^\circ\text{C}$ . Take  $\alpha_0 = 1/234.5$  per  $^\circ\text{C}$ .

**[ 2.76] (Electrical Technology, Allahabad Univ. 1977)**

### OBJECTIVE TESTS – 28

- The external characteristic of a shunt generator can be obtained directly from its ——— characteristic.
  - internal
  - open-circuit
  - load-saturation
  - performance
- Load saturation characteristic of a d.c. generator gives relation between
  - V and  $I_a$
  - E and  $I_a$
  - $E_0$  and  $I_f$
  - V and  $I_f$
- The slight curvature at the lower end of the O.C.C. of a self-excited d.c. generator is due to
  - residual pole flux
  - high armature speed
  - magnetic inertia
  - high field circuit resistance.
- For the voltage built-up of a self-excited d.c. generator, which of the following is not an essential condition ?
  - There must be some residual flux
  - Field winding mmf must aid the residual flux
  - Total field circuit resistance must be less than the critical value
  - Armature speed must be very high.
- The voltage build-up process of a d.c. generator is
  - difficult
  - delayed
  - cumulative
  - infinite
- Which of the following d.c. generator cannot build up on open-circuit ?
  - shunt
  - series
  - short shunt
  - long shunt
- If a self-excited d.c. generator after being installed, fails to build up on its first trial run, the first thing to do is to
  - increase the field resistance
  - check armature insulation
  - reverse field connections
  - increase the speed of prime mover.
- If residual magnetism of a shunt generator is destroyed accidentally, it may be restored by connecting its shunt field
  - to earth
  - to an a.c. source
  - in reverse
  - to a d.c. source.
- The three factors which cause decrease in the terminal voltage of a shunt generator are
  - armature reactances
  - armature resistance
  - armature leakages
  - armature reaction
  - reduction in field current
- If field resistance of a d.c. shunt generator is increased beyond its critical value, the generator
  - output voltage will exceed its name-plate rating
  - will not build up

- (c) may burn out if loaded to its name-plate rating  
 (d) power output may exceed its name-plate rating
11. An ideal d.c. generator is one that has .....  
 (a) low (b) zero  
 (c) positive (d) negative
12. The ..... generator has poorest voltage regulation.  
 (a) series (b) shunt  
 (c) compound (d) high
13. The voltage regulation of an overcompound d.c. generator is always .....
- (a) positive  
 (b) negative  
 (c) zero  
 (d) high
14. Most commercial compound d.c. generator are normally supplied by the manufacturers as over compound machines because  
 (a) they are ideally suited for transmission of d.c. energy to remotely-located loads  
 (b) degree of compounding can be adjusted by using a divertor across series field  
 (c) they are more cost effective than shunt generators  
 (d) they have zero percent regulation.

## ANSWERS

1. (b) 2. (d) 3. (c) 4. (d) 5. (c) 6. (b) 7. (c) 8. (d) 9. (b,d,e) 10. (b) 11. (b) 12. (a) 13. (b) 14. (b).

## QUESTIONS AND ANSWERS ON D.C. GENERATORS

**Q. 1. How may the number of parallel paths in an armature be increased ?**

**Ans.** By increasing the number of magnetic poles.

**Q. 2. How are brushes connected in a d.c. generator ?**

**Ans.** Usually, all positive brushes are connected together and all the negative brushes together (Fig. 28.33).

**Q. 3. What is meant by armature reaction ?**

**Ans.** It is the effect of armature magnetic field on the distribution of flux under main poles of a generator. The armature magnetic field has two effects :

- (i) It demagnetises or weakens the main flux and
- (ii) It cross-magnetises or distorts it.

**Q. 4. What is the effect of this distortion on the operation of the machine ?**

**Ans.** It acts as a magnetic drag on the armature which consequently requires more power to turn it.

**Q. 5. How can field distortion be remedied ?**

**Ans.** By using compensating windings which are embedded in the slots in the pole-shoe and are connected in series with the armature.

**Q. 6. What is meant by normal neutral plane ?**

**Ans.** It is a plane which passes through the axis of the armature perpendicular to the magnetic field of the generator when there is no flow of current through the armature.

**Q. 7. What is the importance of this plane in the working of the machine ?**

**Ans.** It gives the position where brushes would be placed to prevent sparking during the operation of the generator where the main pole field not distorted by armature field and were there no self-induction in the coils.

**Q. 8. How do you differentiate between normal neutral plane ?**

**Ans.** The *NNP* is the position of zero induction and hence minimum sparking assuming no field distortion *i.e.* on no-load. It is perpendicular to magnetic axis. *NA* is the position of zero induction and hence minimum sparking with distorted field *i.e.* **when generator is on load.**

**Q. 9. How do you define 'commutating plane' ?**

**Ans.** It is the plane which passes through the axis of the armature and through centre of contact of the brushes as shown in Fig. 28.34.

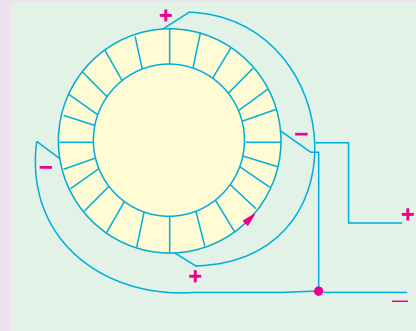

Fig. 28.33

**Q. 10. What is the angle of lead ?**

**Ans.** It is the angle between the *NNP* and the commutating plane.

**Q. 11. What affects this angle ?**

**Ans.** For sparkless commutation, the angle of lead varies directly with load. Its value can be kept small by making main pole field considerably more powerful than the armature field.

**Q. 12. What is the best way of minimizing eddy currents in an armature ?**

**Ans.** Lamination.

**Q. 13. How should the armature be laminated for the purpose ?**

**Ans.** It should be laminated at right angle to its axis.

**Q. 14. How does field distortion affect communication ?**

**Ans.** The neutral plane no longer coincides with the normal neutral plane but is advanced by a certain angle in the direction of rotation of the armature.

**Q. 15. Should the brushes of a loaded generator be placed in the neutral plane ?**

**Ans.** No.

**Q. 16. Why not ?**

**Ans.** The brushes must be advanced by a certain angle (called brush lead) beyond the neutral plane to prevent sparking.

**Q. 17. What causes sparking at the brushes ?**

**Ans.** It is due to the self-induction of the coil undergoing commutation.

**Q. 18. What is the standard direction of rotation of the d.c. generators ?**

**Ans.** Clockwise when viewed from the end opposite to the driven end.

**Q. 19. What is meant by build-up of a generator ?**

**Ans.** It means the gradual increase in the generator voltage to its maximum value after the generator is started from rest.

**Q. 20. How should a generator be started ?**

**Ans.** It is usually brought up to speed with the help of the driving engine called prime-mover.

**Q. 21. How should a shunt or compound generator be started ?**

**Ans.** Such machines excite best when all switches controlling the external circuit are open.

**Q. 22. How about a series generator ?**

**Ans.** In this case, the external circuit must be closed otherwise the generator will not build-up.

**Q. 23. What is the procedure for shunting down a generator ?**

**Ans.** First, the load should be gradually reduced, if possible, by easing down the driving engine, then when the generator is supplying little or no current, the main switch should be opened. When the voltmeter reads almost zero, then brushes should be raised from the commutator.

**Q. 24. What are the indications and causes of an overloaded generator ?**

**Ans.** A generator is said to be overloaded if a greater output is taken from it that it can safely carry. Overloading is indicated by (i) excessive sparking at brushes and (ii) overheating of the armature and other parts of the generator. Most likely causes of overloading are :

1. Excessive voltage—as indicated by the voltmeter or the increased brilliancy of the pilot lamp. This could be due to over-excitation of field magnets or too high speed of the engine.
2. Excessive current—which could be due to bad feeding of the load.
3. Reversal of polarity—this happens occasionally when the series or compound-wound generators are running in parallel. Polarity reversal occurs during stopping by the current from the machines at work.
4. Short-circuit or ground in the generator itself or in the external circuit.

**Q. 25. Mention and explain the various causes for the failure of the generator to build up.**

**Ans.** Principal causes due to which a generator may fail to excite are :

**Fig. 28.34**

1. Brushes not properly adjusted—if brushes are not in their proper positions, then whole of the armature voltage will not be utilized and so would be insufficient to excite the machine.
2. Defective contacts—unclean contacts may interpose large resistance in the path of the exciting current and reduce it to such a small value that it fails to excite the machine.
3. Incorrect adjustment of regulators—in the case of shunt and compound generators, it is possibly that the resistance of field regulator may be too high to permit the passage of sufficient current through the field windings.
4. Speed too low—in the case of shunt—and compound-wound generators, there is certain critical armature speed below which they will not excite.
5. Open-circuit—in the case of series machines.
6. Short-circuit—in the generator of external circuit.
7. Reversed field polarity—usually caused by the reversed connections of the field coils.
8. Insufficient residual magnetism—The trouble normally occurs when the generator is new. It can be remedied by passing a strong direct current through the field coils.

**Q. 26. How do we conclude that connections between field coils and armature are correct ?**

**Ans.** If the generator builds up when brought to full speed. If it does not, then connections are reversed.

**Q. 27. When a generator loses its residual magnetism either due to lighting or short circuit, how can it be made to build up ?**

**Ans.** By temporarily magnetising the main poles with the help of current from an external battery.

**Q. 28. Can a generator be reversed by reversing the connections between the armature and field coils ?**

**Ans.** No, because if these connections are reversed, the generator will not build up at all.

**Q. 29. Will a generator build up if it becomes reversed ?**

**Ans.** Yes.

**Q. 30. Then, what is the objection to a reversed generator ?**

**Ans.** Since the current of such a reversed generator is also reversed, serious trouble can occur if attempt is made to connect it in parallel with other machines which are not reversed.

**Q. 31. What are the two kinds of sparking produced in a generator ?**

**Ans.** One kind of sparking is due to bad adjustment of brushes and the other due to bad condition of the commutator. The sparking of the first are bluish whereas those of the other are reddish in colour.

**Q. 32. What is the probable reason if sparking does not disappear in any position when brushes are rocked around the commutator ?**

**Ans. (i)** The brushes may not be separated at correct distance.

**(ii)** The neutral plane may not be situated in the true theoretical position on the commutator due to faulty winding.

**Q. 33. What is the permissible rise of temperature in a well-designed generator ?**

**Ans.** 27°C above the surrounding air.

**Q. 34. What are the causes of hot bearings ?**

**Ans. (i)** lack of oil **(ii)** belt too tight **(iii)** armature not centered with respect of pole pieces **(iv)** bearing too tight or not in line.

**Q. 35. What causes heating of armature ?**

**Ans. 1.** Eddy currents.

**2.** Moisture which almost short-circuits the armature.

**3.** Unequal strength of magnetic poles.

**4.** Operation above rated voltage and below normal speed.

**Q. 36. What is the commutator pitch of a 4-pole d.c. armature having 49 commutator bars?**

**Ans.**  $Y_c = (49 \pm 1)/2 = 24$  or 25.

**Q. 37. Will it make any difference if lower figure of 24 is selected in preference to other.**

**Ans.** Yes. Direction of armature rotation would be reversed.

## D.C. MOTOR

**C** Design for optimum performance and durability in demanding variable speed motor applications. D.C. motors have earned a reputation for dependability in severe operating conditions

### 29.1. Motor Principle

An Electric motor is a machine which converts electric energy into mechanical energy. Its action is based on the principle that when a current-carrying conductor is placed in a magnetic field, it experiences a mechanical force whose direction is given by Fleming's Left-hand Rule and whose magnitude is given by  $F = BIl$  Newton.

Constructionally, there is no basic difference between a d.c. generator and a d.c. motor. In fact, the same d.c. machine can be used interchangeably as a generator or as a motor. D.C. motors are also like generators, shunt-wound or series-wound or compound-wound.

In Fig. 29.1 a part of multipolar d.c. motor is shown. When its field magnets are excited and its armature conductors

Fig. 29.1

are supplied with current from the supply mains, they experience a force tending to rotate the armature. Armature conductors under *N*-pole are assumed to carry current downwards (crosses) and those under *S*-poles, to carry current upwards (dots). By applying Fleming's Left-hand Rule, the direction of the force on each conductor can be found. It is shown by small arrows placed above each conductor. It will be seen that each conductor experiences a force  $F$  which tends to rotate the armature in anticlockwise direction. These forces collectively produce a driving torque which sets the armature rotating.

It should be noted that the function of a commutator in the motor is the same as in a generator. By reversing current in each conductor as it passes from one pole to another, it helps to develop a continuous and unidirectional torque.

### 29.2. Comparison of Generator and Motor Action

As said above, the same d.c. machine can be used, at least theoretically, interchangeably as a generator or as a motor. When operating as a generator, it is driven by a mechanical machine and it develops voltage which in turn produces a current flow in an electric circuit. When operating as a motor, it is supplied by electric current and it develops torque which in turn produces mechanical rotation.

Fig. 29.2

Let us first consider its operation as a generator and see how exactly and through which agency, mechanical power is converted into electric power.

In Fig. 29.2 part of a generator whose armature is being driven clockwise by its prime mover is shown.

Fig. 29.2 (a) represents the fields set up independently by the main poles and the armature conductors like *A* in the figure. The resultant field or magnetic lines on flux are shown in Fig. 29.2 (b).

It is seen that there is a crowding of lines of flux on the right-hand side of A. These magnetic lines of flux may be likened to the rubber bands under tension. Hence, the bent lines of flux up a mechanical force on A much in the same way as the bent elastic rubber band of a catapult produces a mechanical force on the stone piece. It will be seen that this force is in a direction opposite to that of armature rotation. Hence, it is known as backward force or magnetic drag on the conductors. It is against this drag action on all armature conductor that the prime mover has to work. The work done in overcoming this opposition is converted into electric energy. Therefore, it should be clearly understood that it is only through the instrumentality of this magnetic drag that energy conversion is possible in a d.c. generator\*.

Next, suppose that the above d.c. machine is uncoupled from its prime mover and that current is sent through the armature conductors under a N-pole in the downward direction as shown in Fig. 29.3 (a). The conductors will again experience a force in the anticlockwise direction (Fleming's Left hand Rule). Hence, the machine will start rotating anticlockwise, thereby developing a torque which can produce mechanical rotation. The machine is then said to be motoring.

Fig. 29.3 (a)

Fig. 29.3 (b)

As said above, energy conversion is not possible unless there is some opposition whose overcoming provides the necessary means for such conversion. In the case of a generator, it was the magnetic drag which provided the necessary opposition. But what is the equivalent of that drag in the case of a motor? Well, it is the back e.m.f. It is explained in this manner:

As soon as the armature starts rotating, dynamically (or motionally) induced e.m.f. is produced in the armature conductors. The direction of this induced e.m.f. as found by Fleming's Right-hand Rule, is outwards *i.e.*, in direct opposition to the applied voltage (Fig. 29.3 (b)). This is why it is known as back e.m.f.  $E_b$  or counter e.m.f. Its value is the same as for the motionally induced e.m.f. in the generator *i.e.*  $E_b = (\Phi Z N) \times (P/A)$  volts. The applied voltage  $V$  has to be forced current through the armature conductors against this back e.m.f.  $E_b$ . The electric work done in overcoming this opposition is converted into mechanical energy developed in the armature. Therefore, it is obvious that but for the production of this opposing e.m.f. energy conversion would not have been possible.

Fig. 29.4

Now, before leaving this topic, let it be pointed out that in an actual

motor with slotted armature, the torque is not due to mechanical force on the conductors themselves, but due to tangential pull on the armature teeth as shown in Fig. 29.4.

It is seen from Fig. 29.4 (a) that the main flux is concentrated in the form of tufts at the armature teeth while the armature flux is shown by the dotted lines embracing the armature slots. The effect of

\* In fact, it seems to be one of the fundamental laws of Nature that no energy conversion from one form to another is possible until there is some one to oppose the conversion. But for the presence of this opposition, there would simply be no energy conversion. In generators, opposition is provided by magnetic drag whereas in motors, back e.m.f. does this job. Moreover, it is only that part of the input energy which is used for overcoming this opposition that is converted into the other form.

armature flux on the main flux, as shown in Fig. 29.4 (b), is two-fold :

- (i) It increases the flux on the left-hand side of the teeth and decreases it on the right-hand side, thus making the distribution of flux density across the tooth section unequal.
- (ii) It inclines the direction of lines of force in the air-gap so that they are not radial but are disposed in a manner shown in Fig. 29.4 (b). The pull exerted by the poles on the teeth can now be resolved into two components. One is the tangential component  $F_1$  and the other vertical component  $F_2$ . The vertical component  $F_2$ , when considered for all the teeth round the armature, adds up to zero. But the component  $F_1$  is not cancelled and it is this tangential component which, acting on all the teeth, gives rise to the armature torque.

### 29.3. Significance of the Back e.m.f.

As explained in Art 29.2, when the motor armature rotates, the conductors also rotate and hence cut the flux. In accordance with the laws of electromagnetic induction, e.m.f. is induced in them whose direction, as found by Fleming's Right-hand Rule, is in opposition to the applied voltage (Fig. 29.5). Because of its opposing direction, it is referred to as counter e.m.f. or back e.m.f.  $E_b$ . The equivalent circuit of a motor is shown in Fig. 29.6. The rotating armature generating the back e.m.f.  $E_b$  is like a battery of e.m.f.  $E_b$  put across a supply mains of  $V$  volts. Obviously,  $V$  has to drive  $I_a$  against the opposition of  $E_b$ . The power required to overcome this opposition is  $E_b I_a$ .

Fig. 29.5

In the case of a cell, this power over an interval of time is converted into chemical energy, but in the present case, it is converted into mechanical energy.

$$\text{It will be seen that } I_a = \frac{\text{Net voltage}}{\text{Resistance}} = \frac{V - E_b}{R_a}$$

where  $R_a$  is the resistance of the armature circuit. As pointed out above,

$$E_b = \Phi ZN \times (P/A) \text{ volt where } N \text{ is in r.p.s.}$$

Back e.m.f. depends, among other factors, upon the armature speed. If speed is high,  $E_b$  is large, hence armature current  $I_a$ , seen from the above equation, is small. If the speed is less, then  $E_b$  is less, hence more current flows which develops motor torque (Art 29.7). So, we find that  $E_b$  acts like a governor *i.e.*, it makes a motor self-regulating so that it draws as much current as is just necessary.

### 29.4. Voltage Equation of a Motor

The voltage  $V$  applied across the motor armature has to

- (i) overcome the back e.m.f.  $E_b$  and
- (ii) supply the armature ohmic drop  $I_a R_a$ .

$$\therefore V = E_b + I_a R_a$$

This is known as voltage equation of a motor.

Now, multiplying both sides by  $I_a$ , we get

$$V I_a = E_b I_a + I_a^2 R_a$$

As shown in Fig. 29.6,

$$V I_a = \text{Electrical input to the armature}$$

$$E_b I_a = \text{Electrical equivalent of mechanical power developed in the armature}$$

$$I_a^2 R_a = \text{Cu loss in the armature}$$

Hence, out of the armature input, some is wasted in  $I^2 R$  loss and the rest is converted into mechanical power *within* the armature.

It may also be noted that motor efficiency is given by the ratio of power developed by the arma-

Fig. 29.6

ture to its input *i.e.*,  $E_b I_a / V I_a = E_b / V$ . Obviously, higher the value of  $E_b$  as compared to  $V$ , higher the motor efficiency.

### 29.5. Condition for Maximum Power

The gross mechanical power developed by a motor is  $P_m = V I_a - I_a^2 R_a$ .

Differentiating both sides with respect to  $I_a$  and equating the result to zero, we get

$$dP_m/dI_a = V - 2I_a R_a = 0 \quad \therefore I_a R_a = V/2$$

$$\text{As } V = E_b + I_a R_a \quad \text{and} \quad I_a R_a = V/2 \quad \therefore E_b = V/2$$

Thus gross mechanical power developed by a motor is maximum when back e.m.f. is equal to half the applied voltage. This condition is, however, not realized in practice, because in that case current would be much beyond the normal current of the motor. Moreover, half the input would be wasted in the form of heat and taking other losses (mechanical and magnetic) into consideration, the motor efficiency will be well below 50 percent.

**Example 29.1.** A 220-V d.c. machine has an armature resistance of  $0.5 \Omega$ . If the full-load armature current is 20 A, find the induced e.m.f. when the machine acts as (i) generator (ii) motor.

(Electrical Technology-I, Bombay Univ. 1987)

Fig. 29.7

**Solution.** As shown in Fig. 29.7, the d.c. machine is assumed to be shunt-connected. In each case, shunt current is considered negligible because its value is not given.

(a) As Generator [Fig. 29.7(a)]  $E_g = V + I_a R_a = 220 + 0.5 \times 20 = 230 \text{ V}$

(b) As Motor [Fig. 29.7 (b)]  $E_b = V - I_a R_a = 220 - 0.5 \times 20 = 210 \text{ V}$

**Example 29.2.** A separately excited D.C. generator has armature circuit resistance of  $0.1 \text{ ohm}$  and the total brush-drop is  $2 \text{ V}$ . When running at  $1000 \text{ r.p.m.}$ , it delivers a current of  $100 \text{ A}$  at  $250 \text{ V}$  to a load of constant resistance. If the generator speed drop to  $700 \text{ r.p.m.}$ , with field-current unaltered, find the current delivered to load. (AMIE, Electrical Machines, 2001)

**Solution.**  $R_L = 250/100 = 2.5 \text{ ohms.}$

$$E_{g1} = 250 + (100 \times 0.1) + 2 = 262 \text{ V.}$$

$$\text{At } 700 \text{ r.p.m., } E_{g2} = 262 \times 700/1000 = 183.4 \text{ V}$$

$$\text{If } I_a \text{ is the new current, } E_{g2} - 2 - (I_a \times 0.1) = 2.5 I_a$$

This gives  $I_a = 96.77 \text{ amp.}$

**Extension to the Question :** With what load resistance will the current be  $100 \text{ amp}$ , at  $700 \text{ r.p.m.}$ ?

**Solution.**  $E_{g2} - 2 - (I_a \times 0.1) = R_L \times I_a$

For  $I_a = 100 \text{ amp}$ , and  $E_{g2} = 183.4 \text{ V}$ ,  $R_L = 1.714 \text{ ohms.}$

**Example 29.3.** A  $440\text{-V}$ , shunt motor has armature resistance of  $0.8 \Omega$  and field resistance of  $200 \Omega$ . Determine the back e.m.f. when giving an output of  $7.46 \text{ kW}$  at  $85 \text{ percent}$  efficiency.

**Solution.** Motor input power =  $7.46 \times 10^3 / 0.85 \text{ W}$

Motor input current =  $7460/0.85 \times 440 = 19.95 \text{ A}$  ;  $I_{sh} = 440/200 = 2.2 \text{ A}$

$I_a = 19.95 - 2.2 = 17.75 \text{ A}$  ; Now,  $E_b = V - I_a R_a$

$\therefore E_b = 440 - (17.75 \times 0.8) = 425.8 \text{ V}$

Fig. 29.8 (a)

Fig. 29.8 (b)

**Example 29.4.** A 25-kW, 250-V, d.c. shunt generator has armature and field resistances of  $0.06 \Omega$  and  $100 \Omega$  respectively. Determine the total armature power developed when working (i) as a generator delivering 25 kW output and (ii) as a motor taking 25 kW input.

(Electrical Technology, Punjab Univ., June 1991)

**Solution. As Generator** [Fig. 29.8 (a)]

Output current =  $25,000/250 = 100 \text{ A}$  ;  $I_{sh} = 250/100 = 2.5 \text{ A}$  ;  $I_a = 102.5 \text{ A}$

Generated e.m.f. =  $250 + I_a R_a = 250 + 102.5 \times 0.06 = 256.15 \text{ V}$

Power developed in armature =  $E_b I_a = \frac{256.15 \times 102.5}{1000} = 26.25 \text{ kW}$

**As Motor** [Fig 29.8 (b)]

Motor input current =  $100 \text{ A}$  ;  $I_{sh} = 2.5 \text{ A}$ ,  $I_a = 97.5 \text{ A}$

$E_b = 250 - (97.5 \times 0.06) = 250 - 5.85 = 244.15 \text{ V}$

Power developed in armature =  $E_b I_a = 244.15 \times 97.5/1000 = 23.8 \text{ kW}$

**Example 29.5.** A 4 pole, 32 conductor, lap-wound d.c. shunt generator with terminal voltage of 200 volts delivering 12 amps to the load has  $r_a = 2$  and field circuit resistance of 200 ohms. It is driven at 1000 r.p.m. Calculate the flux per pole in the machine. If the machine has to be run as a motor with the same terminal voltage and drawing 5 amps from the mains, maintaining the same magnetic field, find the speed of the machine. [Sambalpur University, 1998]

**Solution.** Current distributions during two actions are indicated in Fig. 29.9 (a) and (b). As a generator,  $I_a = 13 \text{ amp}$

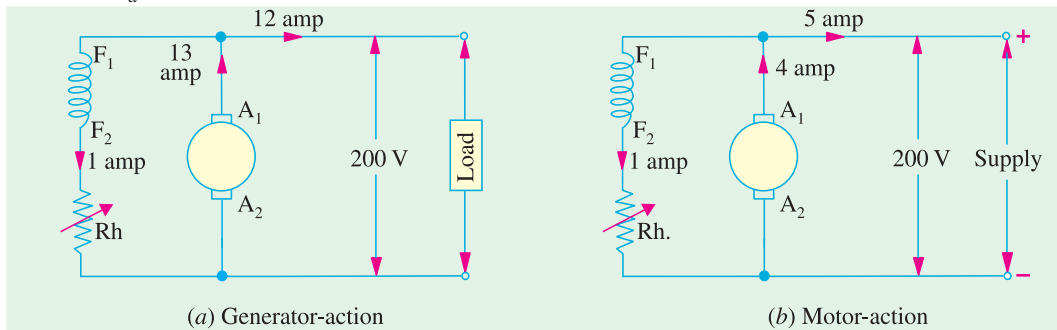

Fig. 29.9

$E_g = 200 + 13 \times 2 = 226 \text{ V}$

$$\phi \frac{ZN}{60} \times \frac{P}{a} = 226$$

For a Lap-wound armature,

$$P = a$$

$$\therefore \phi = \frac{226 \times 60}{1000 \times 32} = 0.42375 \text{ wb}$$

As a motor,

$$I_a = 4 \text{ amp}$$

$$E_b = 200 - 4 \times 2 = 192 \text{ V}$$

$$= \phi ZN/60$$

$$\text{Giving } N = \frac{60 \times 192}{0.42375 \times 32}$$

$$= 850 \text{ r.p.m.}$$

### Tutorial Problems 29.1

1. What do you understand by the term 'back e.m.f.'? A d.c. motor connected to a 460-V supply has an armature resistance of 0.15 Ω. Calculate

(a) The value of back e.m.f. when the armature current is 120 A.

(b) The value of armature current when the back e.m.f. is 447.4 V. **[(a) 442 V (b) 84 A]**

2. A d.c. motor connected to a 460-V supply takes an armature current of 120 A on full load. If the armature circuit has a resistance of 0.25 Ω, calculate the value of the back e.m.f. at this load. **[430 V]**

3. A 4-pole d.c. motor takes an armature current of 150 A at 440 V. If its armature circuit has a resistance of 0.15 Ω, what will be the value of back e.m.f. at this load? **[417.5 V]**

### 29.6. Torque

By the term torque is meant the turning or twisting moment of a force about an axis. It is measured by the product of the force and the radius at which this force acts.

Consider a pulley of radius  $r$  metre acted upon by a circumferential force of  $F$  Newton which causes it to rotate at  $N$  r.p.m. (Fig. 29.10).

Then torque  $T = F \times r$  Newton-metre (N - m)

Work done by this force in one revolution

$$= \text{Force} \times \text{distance} = F \times 2\pi r \text{ Joule}$$

Power developed =  $F \times 2\pi r \times N$  Joule/second or Watt

$$= (F \times r) \times 2\pi N \text{ Watt}$$

Now  $2\pi N =$  Angular velocity  $\omega$  in radian/second and  $F \times r =$  Torque  $T$

$\therefore$  Power developed =  $T \times \omega$  watt or  $P = T \omega$  Watt

Moreover, if  $N$  is in r.p.m., then

$$\omega = 2\pi N/60 \text{ rad/s}$$

$$\therefore P = \frac{2\pi N}{60} \times T \text{ or } P = \frac{2\pi}{60} \cdot NT = \frac{NT}{9.55}$$

Fig. 29.10

### 29.7. Armature Torque of a Motor

Let  $T_a$  be the torque developed by the armature of a motor running at  $N$  r.p.s. If  $T_a$  is in  $N/M$ , then power developed =  $T_a \times 2\pi N$  watt ...(i)

We also know that electrical power converted into mechanical power in the armature (Art 29.4)

$$= E_b I_a \text{ watt} \quad \dots(ii)$$

Equating (i) and (ii), we get  $T_a \times 2\pi N = E_b I_a \quad \dots(iii)$

Since  $E_b = \Phi ZN \times (P/A)$  volt, we have

$$T_a \times 2\pi N = \Phi ZN \left(\frac{P}{A}\right) \cdot I_a \text{ or } T_a = \frac{1}{2\pi} \cdot \Phi Z I_0 \left(\frac{P}{A}\right) N\text{-m}$$

$$= 0.159 \text{ N newton metre}$$

$$\therefore T_a = 0.159 \Phi Z I_a \times (P/A) N\text{-m}$$

**Note.** From the above equation for the torque, we find that  $T_a \propto \Phi I_a$ .

(a) In the case of a series motor,  $\Phi$  is directly proportional to  $I_a$  (before saturation) because field windings carry full armature current  $\therefore T_a \propto I_a^2$

(b) For shunt motors,  $\Phi$  is practically constant, hence  $T_a \propto I_a$ .

As seen from (iii) above

$$T_a = \frac{E_b I_a}{2\pi N} \text{ N - m - N in r.p.s.}$$

If  $N$  is in r.p.m., then

$$T_a = \frac{E_b I_a}{2\pi N / 60} = 60 \frac{E_b I_a}{2\pi N} = \frac{60}{2\pi} \frac{E_b I_a}{N} = 9.55 \frac{E_b I_a}{N} \text{ N-m}$$

### 29.8. Shaft Torque ( $T_{sh}$ )

The whole of the armature torque, as calculated above, is not available for doing useful work, because a certain percentage of it is required for supplying iron and friction losses in the motor.

The torque which is available for doing useful work is known as shaft torque  $T_{sh}$ . It is so called because it is available at the shaft. The motor output is given by

Output =  $T_{sh} \times 2\pi N$  Watt provided  $T_{sh}$  is in N-m and  $N$  in r.p.s.

$$\therefore T_{sh} = \frac{\text{Output in watts}}{2\pi N} \text{ N-m -N in r.p.s}$$

$$= \frac{\text{Output in watts}}{2\pi N / 60} \text{ N-m -N in r.p.m.}$$

$$= \frac{60}{2\pi} \frac{\text{output}}{N} = 9.55 \frac{\text{Output}}{N} \text{ N-m.}$$

The difference ( $T_a - T_{sh}$ ) is known as lost torque and is due to iron and friction losses of the motor.

**Note.** The value of back e.m.f.  $E_b$  can be found from

(i) the equation,  $E_b = V - I_a R_a$

(ii) the formula  $E_b = \Phi ZN \times (P/A)$  volt

**Example 29.6.** A d.c. motor takes an armature current of 110 A at 480 V. The armature circuit resistance is 0.2  $\Omega$ . The machine has 6-poles and the armature is lap-connected with 864 conductors. The flux per pole is 0.05 Wb. Calculate (i), the speed and (ii) the gross torque developed by the armature. **(Elect. Machines, A.M.I.E. Sec B, 1989)**

**Solution.**  $E_b = 480 - 110 \times 0.2 = 458 \text{ V}, \quad \Phi = 0.05 \text{ Wb}, Z = 864$

Now,  $E_b = \frac{\Phi ZN}{60} \left(\frac{P}{A}\right)$  or  $458 = \frac{0.05 \times 864 \times N}{60} \times \left(\frac{6}{6}\right)$

$$\therefore N = 636 \text{ r.p.m.}$$

$$T_a = 0.159 \times 0.05 \times 864 \times 110 (6/6) = 756.3 \text{ N-m}$$

**Example 29.7.** A 250-V, 4-pole, wave-wound d.c. series motor has 782 conductors on its armature. It has armature and series field resistance of 0.75 ohm. The motor takes a current of 40 A. Estimate its speed and gross torque developed if it has a flux per pole of 25 mWb.

(Elect. Engg.-II, Pune Univ. 1991)

**Solution.**

$$E_b = \Phi ZN (P/A)$$

Now,

$$E_b = V - I_a R_a = 250 - 40 \times 0.75 = 220 \text{ V}$$

$$\therefore 220 = 25 \times 10^{-3} \times 782 \times N \times 0.75 = 220 \text{ V}$$

$$\therefore 220 = 0.159 \Phi Z I_a (P/A)$$

$$= 0.159 \times 25 \times 10^{-3} \times 782 \times 40 \times (4/2) = \mathbf{249 \text{ N-m}}$$

**Example 29.8.** A d.c. shunt machine develops an a.c. e.m.f. of 250 V at 1500 r.p.m. Find its torque and mechanical power developed for an armature current of 50 A. State the simplifying assumptions.

(Basic Elect. Machine Nagpur Univ., 1993)

**Solution.** A given d.c. machine develops the same e.m.f. in its armature conductors whether running as a generator or as a motor. Only difference is that this armature e.m.f. is known as back e.m.f. when the machine is running as a motor.

Mechanical power developed in the arm =  $E_b I_a = 250 \times 50 = 12,500 \text{ W}$   
 $T_a = 9.55 E_b I_a / N = 9.55 \times 250 \times 50 / 1500 = \mathbf{79.6 \text{ N-m.}}$

**Example 29.9.** Determine developed torque and shaft torque of 220-V, 4-pole series motor with 800 conductors wave-connected supplying a load of 8.2 kW by taking 45 A from the mains. The flux per pole is 25 mWb and its armature circuit resistance is 0.6 Ω.

(Elect. Machine AMIE Sec. B Winter 1991)

**Solution.** Developed torque or gross torque is the same thing as armature torque.

$$\therefore T_a = 0.159 \Phi Z A (P/A)$$

$$= 0.159 \times 25 \times 10^{-3} \times 800 \times 45 (4/2) = 286.2 \text{ N-m}$$

$$E_b = V - I_a R_a = 220 - 45 \times 0.6 = 193 \text{ V}$$

Now,

$$E_b = \Phi ZN (P/A) \text{ or } 193 = 25 \times 10^{-3} \times 800 \times N \pi \times (4/2)$$

$$\therefore N = 4.825 \text{ r.p.s.}$$

Also,

$$2\pi N T_{sh} = \text{output or } 2\pi \times 4.825 T_{sh} = 8200 \quad \therefore T_{sh} = 270.5 \text{ N-m}$$

**Example 29.10.** A 220-V d.c. shunt motor runs at 500 r.p.m. when the armature current is 50 A. Calculate the speed if the torque is doubled. Given that  $R_a = 0.2 \Omega$ .

(Electrical Technology-II, Gwalior Univ. 1985)

**Solution.** As seen from Art 27.7,  $T_a \propto \Phi I_a$ . Since  $\Phi$  is constant,  $T_a \propto I_a$

$$\therefore T_{a1} \propto I_{a1} \text{ and } T_{a2} \propto I_{a2} \quad \therefore T_{a2}/T_{a1} = I_{a2}/I_{a1}$$

$$\therefore 2 = I_{a2}/50 \text{ or } I_{a2} = 100 \text{ A}$$

Now,  $N_2/N_1 = E_{b2}/E_{b1}$  — since  $\Phi$  remains constant.

$$F_{b1} = 220 - (50 \times 0.2) = 210 \text{ V} \quad E_{b2} = 220 - (100 \times 0.2) = 200 \text{ V}$$

$$\therefore N_2/500 = 200/210 \quad \therefore N_2 = \mathbf{476 \text{ r.p.m.}}$$

**Example 29.11.** A 500-V, 37.3 kW, 1000 r.p.m. d.c. shunt motor has on full-load an efficiency of 90 percent. The armature circuit resistance is 0.24 Ω and there is total voltage drop of 2 V at the brushes. The field current is 1.8 A. Determine (i) full-load line current (ii) full load shaft torque in N-m and (iii) total resistance in motor starter to limit the starting current to 1.5 times the full-load current.

(Elect. Engg. I; M.S. Univ. Baroda 1987)

**Solution.** (i) Motor input =  $37,300/0.9 = 41,444 \text{ W}$   
 F.L. line current =  $41,444/500 = \mathbf{82.9 \text{ A}}$

$$(ii) \quad T_{sh} = 9.55 \frac{\text{output}}{N} = 9.55 \times \frac{37,300}{1000} = 356 \text{ N-m}$$

$$(iii) \quad \text{Starting line current} = 1.5 \times 82.9 = 124.3 \text{ A}$$

$$\text{Arm. current at starting} = 124.3 - 1.8 = 122.5 \text{ A}$$

If  $R$  is the starter resistance (which is in series with armature), then  
 $122.5 (R + 0.24) + 2 = 500 \quad \therefore R = 3.825 \Omega$

**Example 29.12.** A 4-pole, 220-V shunt motor has 540 lap-wound conductor. It takes 32 A from the supply mains and develops output power of 5.595 kW. The field winding takes 1 A. The armature resistance is  $0.09 \Omega$  and the flux per pole is 30 mWb. Calculate (i) the speed and (ii) the torque developed in newton-metre. (Electrical Technology, Nagpur Univ. 1992)

**Solution.**  $I_a = 32 - 1 = 31 \text{ A}$ ;  $E_b = V - I_a R_a = 220 - (0.09 \times 31) = 217.2 \text{ V}$

Now, 
$$E_b = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right) \quad \therefore 217.2 = \frac{30 \times 10^{-3} \times 540 \times N}{60} \left( \frac{4}{4} \right)$$

(i)  $\therefore N = 804.4 \text{ r.p.m.}$

(ii) 
$$T_{sh} = 9.55 \times \frac{\text{output in watts}}{N} = 9.55 \times \frac{5,595}{804.4} = 66.5 \text{ N-m}$$

**Example 29.13 (a).** Find the load and full-load speeds for a four-pole, 220-V, and 20-kW, shunt motor having the following data :

Field-current = 5 amp, armature resistance = 0.04 ohm,

Flux per pole = 0.04 Wb, number of armature-conductors = 160, Two-circuit wave-connection, full load current = 95 amp, No load current = 9 A. Neglect armature reaction.

(Bharathithasan Univ. April 1997)

**Solution.** The machine draws a supply current of 9 amp at no load. Out of this, 5 amps are required for the field circuit, hence the armature carries a no-load current of 4 amp.

At load, armature-current is 90 amp. The armature-resistance-drop increases and the back e.m.f. decreases, resulting into decrease in speed under load compared to that at No-Load.

At No Load :  $E_{ao} = 220 - 4 \times 0.04 = 219.84 \text{ volts}$

Substituting this,

$$0.04 \times 160 \times (N/60) \times (4/2) = 219.84$$

No-Load speed,  $N_0 = 1030.5 \text{ r.p.m.}$

At Full Load : Armature current = 90 A,  $E_a = 200 - 90 \times 0.04 = 216.4 \text{ V}$

$$N = (216.4/219.84) \times 1030.5 = 1014.4 \text{ r.p.m.}$$

**Example 29.13 (b).** Armature of a 6-pole, 6-circuit D.C. shunt motor takes 400 A at a speed of 350 r.p.m. The flux per pole is 80 milli-webers, the number of armature turns is 600, and 3% of the torque is lost in windage, friction and iron-loss. Calculate the brake-horse-power.

(Manonmaniam Sundaranar Univ. Nov. 1998)

**Solution.** Number of armature turns = 600

Therefore,  $Z = \text{Number of armature conductors} = 1200$

If electromagnetic torque developed is  $T \text{ Nw - m}$ ,

$$\begin{aligned} \text{Armature power} &= T \omega = T \times 2 \pi 350/60 \\ &= 36.67 T \text{ watts} \end{aligned}$$

To calculate armature power in terms of Electrical parameters,  $E$  must be known.

$$E = \phi Z (N/60) (P/A)$$

$$= 80 \times 10^{-3} \times 1200 \times (350/60) \times (6/6)$$

$$= 560 \text{ volts}$$

With the armature current of 400 A, Armature power = 560 × 400 watts

Equating the two,

$T = 560 \times 400/36.67 = 6108.5 \text{ Nw - m}$ . Since 3 % of this torque is required for overcoming different loss-terms,

$$\text{Net torque} = 0.97 \times 6108.5 = 5925 \text{ Nw - m}$$

For Brake-Horse-Power, net output in kW should be computed first. Then “kW” is to be converted to “BHP”, with 1 HP = 0.746 kW.

$$\text{Net output in kW} = 5925 \times 36.67 \times 10^{-3} = 217.27 \text{ kW}$$

Converting this to BHP, the output = 291.25 HP

**Example 29.13 (c).** Determine the torque established by the armature of a four-pole D.C. motor having 774 conductors, two paths in parallel, 24 milli-webers of pole-flux and the armature current is 50 Amps. (Bharathiar Univ. April 1998)

**Solution.** Expression for torque in terms of the parameters concerned in this problem is as follows :

$$T = 0.159 \phi Z I_a p/a \text{ Nw - m}$$

Two paths in parallel for a 4-pole case means a wave winding.

$$T = 0.159 \times (24 \times 10^{-3}) \times 774 \times 50 \times 4/2$$

$$= 295.36 \text{ Nw-m}$$

**Example 29.13 (d).** A 500-V D.C. shunt motor draws a line-current of 5 A on light-load. If armature resistance is 0.15 ohm and field resistance is 200 ohms, determine the efficiency of the machine running as a generator delivering a load current of 40 Amps. (Bharathiar Univ. April 1998)

**Solution. (i)** No Load, running as a motor :

$$\text{Input Power} = 500 \times 5 = 2500 \text{ watts}$$

$$\text{Field copper-loss} = 500 \times 2.5 = 1250 \text{ watts}$$

Neglecting armature copper-loss at no load (since it comes out to be  $2.5^2 \times 0.15 = 1$  watt), the balance of 1250 watts of power goes towards no load losses of the machine running at rated speed. These losses are mainly the no load mechanical losses and the core-loss.

**(ii)** As a Generator, delivering 40 A to load :

$$\text{Output delivered} = 500 \times 40 \times 10^{-3} = 20 \text{ kW}$$

Losses : **(a)** Field copper-loss = 1250 watts

**(b)** Armature copper-loss =  $42.5^2 \times 0.15 = 271$  watts

**(c)** No load losses = 1250 watts

Total losses = 2.771 kW

Generator Efficiency =  $(20/22.771) \times 100 \% = 87.83 \%$

**Extension to the Question :** At what speed should the Generator be run, if the shunt-field is not changed, in the above case ? Assume that the motor was running at 600 r.p.m. Neglect armature reaction.

**Solution.** As a motor on no-load,

$$E_{b0} = 500 - I_a r_a = 500 - 0.15 \times 2.5 = 499.625 \text{ V}$$

As a Generator with an armature current of 42.5 A,

$$E_{b0} = 500 + 42.5 \times 0.15 = 506.375 \text{ V}$$

Since, the terminal voltage is same in both the cases, shunt field current remains as 2.5 amp. With armature reaction is ignored, the flux/pole remains same. The e.m.f. then becomes proportional to the speed. If the generator must be driven at  $N$  r.p.m.

$$N = (506.375/449.625) \times 600 = 608.1 \text{ r.p.m.}$$

Fig. 29.11

**Note.** Alternative to this slight increase in the speed is to increase the field current with the help of decreasing the rheostatic resistance in the field-circuit.

**Example 29.13 (e).** A d.c. series motor takes 40 A at 220 V and runs at 800 r.p.m. If the armature and field resistance are 0.2 Ω and 0.1 Ω respectively and the iron and friction losses are 0.5 kW, find the torque developed in the armature. What will be the output of the motor ?

**Solution.** Armature torque is given by  $T_a = 9.55 \frac{E_b I_a}{N}$  N-m

Now  $E_b = V - I_a (R_a + R_{se}) = 220 - 40 (0.2 + 0.1) = 208 \text{ V}$

$\therefore T_a = 9.55 \times 208 \times 40/800 = 99.3 \text{ N-m}$

Cu loss in armature and series-field resistance =  $40^2 \times 0.3 = 480 \text{ W}$

Iron and friction losses = 500 W ; Total losses = 480 + 500 = 980 W

Motor power input =  $220 \times 40 = 8,800 \text{ W}$

Motor output =  $8,800 - 980 = 7,820 \text{ W} = 7.82 \text{ kW}$

**Example 29.14.** A cutting tool exerts a tangential force of 400 N on a steel bar of diameter 10 cm which is being turned in a simple lathe. The lathe is driven by a chain at 840 r.p.m. from a 220 V d.c. Motor which runs at 1800 r.p.m. Calculate the current taken by the motor if its efficiency is 80 %. What size is the motor pulley if the lathe pulley has a diameter of 24 cm ?

(Elect. Technology-II, Gwalior Univ. 1985)

**Solution.** Torque  $T_{sh} = \text{Tangential force} \times \text{radius} = 400 \times 0.05 = 20 \text{ N-m}$

Output power =  $T_{sh} \times 2\pi N \text{ watt} = 20 \times 2\pi \times (840/60) \text{ watt} = 1,760 \text{ W}$

Motor  $\eta = 0.8 \therefore$  Motor input =  $1,760/0.8 = 2,200 \text{ W}$

Current drawn by motor =  $2200/220 = 10 \text{ A}$

Let  $N_1$  and  $D_1$  be the speed and diameter of the driver pulley respectively and  $N_2$  and  $D_2$  the respective speed and diameter of the lathe pulley.

Then  $N_1 \times D_1 = N_2 \times D_2$  or  $1,800 \times D_1 = 840 \times 0.24$

$\therefore D_1 = 840 \times 0.24/1,800 = 0.112 \text{ m} = 11.2 \text{ cm}$

**Example 29.15.** The armature winding of a 200-V, 4-pole, series motor is lap-connected. There are 280 slots and each slot has 4 conductors. The current is 45 A and the flux per pole is 18 mWb. The field resistance is 0.3 Ω; the armature resistance 0.5 Ω and the iron and friction losses total 800 W. The pulley diameter is 0.41 m. Find the pull in newton at the rim of the pulley.

(Elect. Engg. AMIETE Sec. A. 1991)

**Solution.**

$$E_b = V - I_a R_a = 200 - 45(0.5 + 0.3) = 164 \text{ V}$$

Now

$$E_b = \frac{\Phi ZN}{60} \cdot \left(\frac{P}{A}\right) \text{ volt}$$

$$\therefore 164 = \frac{18 \times 10^{-3} \times 280 \times 4 \times N}{60} \times \frac{4}{4} \quad \therefore N = 488 \text{ r.p.m.}$$

$$\text{Total input} = 200 \times 45 = 9,000 \text{ W}; \text{ Cu loss} = I_a^2 R_a = 45^2 \times 0.8 = 1,620 \text{ W}$$

$$\text{Iron + Friction losses} = 800 \text{ W}; \text{ Total losses} = 1,620 + 800 = 2,420 \text{ W}$$

$$\text{Output} = 9,000 - 2,420 = 6,580 \text{ W}$$

$$\therefore T_{sh} = 9 \times 55 \times \frac{6580}{488} = 128 \text{ N-m}$$

Let  $F$  be the pull in newtons at the rim of the pulley.

$$\text{Then } F \times 0.205 = 128.8 \quad \therefore F = 128.8/0.205 \text{ N} = \mathbf{634 \text{ N}}$$

**Example 29.16.** A 4-pole, 240 V, wave connected shunt motor gives 1119 kW when running at 1000 r.p.m. and drawing armature and field currents of 50 A and 1.0 A respectively. It has 540 conductors. Its resistance is 0.1  $\Omega$ . Assuming a drop of 1 volt per brush, find (a) total torque (b) useful torque (c) useful flux / pole (d) rotational losses and (e) efficiency.

**Solution.**

$$E_b = V - I_a R_a - \text{brush drop} = 240 - (50 \times 0.1) - 2 = 233 \text{ V}$$

Also

$$I_a = 50 \text{ A}$$

$$(a) \quad \text{Armature torque } T_a = 9.55 \frac{E_b I_a}{N} \text{ N-m} = 9.55 \times \frac{233 \times 50}{1000} = \mathbf{111 \text{ N-m}}$$

$$(b) \quad T_{sh} = 9.55 \frac{\text{output}}{N} = 9.55 \times \frac{11,190}{1000} = \mathbf{106.9 \text{ N-m}}$$

$$(c) \quad E_b = \frac{\Phi ZN}{60} \times \left(\frac{P}{A}\right) \text{ volt}$$

$$\therefore 233 = \frac{\Phi \times 540 \times 1000}{60} \times \left(\frac{4}{2}\right) \quad \therefore \Phi = \mathbf{12.9 \text{ mWb}}$$

$$(d) \quad \text{Armature input} = V I_a = 240 \times 50 = \mathbf{12,000 \text{ W}}$$

$$\text{Armature Cu loss} = I_a^2 R_a = 50^2 \times 0.1 = 250 \text{ W}; \text{ Brush contact loss} = 50 \times 2 = 100 \text{ W}$$

$$\therefore \text{Power developed} = 12,000 - 350 = 11,650 \text{ W}; \text{ Output} = 11.19 \text{ kW} = 11,190 \text{ W}$$

$$\therefore \text{Rotational losses} = 11,650 - 11,190 = \mathbf{460 \text{ W}}$$

$$(e) \quad \text{Total motor input} = VI = 240 \times 51 = 12,340 \text{ W}; \text{ Motor output} = 11,190 \text{ W}$$

$$\therefore \text{Efficiency} = \frac{11,190}{12,340} \times 100 = \mathbf{91.4 \%}$$

**Example 29.17.** A 460-V series motor runs at 500 r.p.m. taking a current of 40 A. Calculate the speed and percentage change in torque if the load is reduced so that the motor is taking 30 A. Total resistance of the armature and field circuits is 0.8  $\Omega$ . Assume flux is proportional to the field current.

(Elect. Engg.-II, Kerala Univ. 1988)

**Solution.** Since  $\Phi \propto I_a$ , hence  $T \propto I_a^2$ 

$$\therefore T_1 \propto 40^2 \text{ and } T_2 \propto 30^2 \quad \therefore \frac{T_2}{T_1} = \frac{9}{16}$$

 $\therefore$  Percentage change in torque is

$$= \frac{T_1 - T_2}{T_1} \times 100 = \frac{7}{16} \times 100 = \mathbf{43.75 \%}$$

$$\text{Now } E_{b1} = 460 - (40 \times 0.8) = 428 \text{ V}; E_{b2} = 460 - (30 \times 0.8) = 436 \text{ V}$$

$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{I_{a1}}{I_{a2}} \quad \therefore \frac{N_2}{500} = \frac{436}{428} \times \frac{40}{30} \quad \therefore N_2 = \mathbf{679 \text{ r.p.m.}}$$

**Example 29.18.** A 460-V, 55.95 kW, 750 r.p.m. shunt motor drives a load having a moment of inertia of  $252.8 \text{ kg-m}^2$ . Find approximate time to attain full speed when starting from rest against full-load torque if starting current varies between 1.4 and 1.8 times full-load current.

**Solution.** Let us suppose that the starting current has a steady value of  $(1.4 + 1.8)/2 = 1.6$  times full-load value.

$$\text{Full-load output} = 55.95 \text{ kW} = 55,950 \text{ W} ; \text{ Speed} = 750 \text{ r.p.m.} = 12.5 \text{ r.p.s.}$$

$$\text{F.L. shaft torque } T = \text{power}/\omega = \text{power}/2\pi N = 55,950 / \pi \times (750/60) = 712.4 \text{ N-m}$$

During starting period, average available torque

$$= 1.6 T - T = 0.6 T = 0.6 \times 712.4 = 427.34 \text{ N-m}$$

This torque acts on the moment of inertia  $I = 252.8 \text{ kg-m}^2$ .

$$\therefore 427.4 = 252.8 \times \frac{d\omega}{dt} = 252.8 \times \frac{2\pi \times 12.5}{dt}, \quad \therefore dt = 46.4 \text{ s}$$

**Example 29.19.** A 14.92 kW, 400 V, 400 r.p.m. d.c. shunt motor draws a current of 40 A when running at full-load. The moment of inertia of the rotating system is  $7.5 \text{ kg-m}^2$ . If the starting current is 1.2 times full-load current, calculate

(a) full-load torque

(b) the time required for the motor to attain the rated speed against full-load.

(Electrical Technology, Gujarat Univ. 1988)

**Solution.** (a) F.L. output  $14.92 \text{ kW} = 14,920 \text{ W}$  ; Speed = 400 r.p.m. =  $20/3$  r.p.s

$$\text{Now, } T\omega = \text{output} \therefore T = 14,920 / 2\pi \times (20/3) = 356 \text{ N-m}$$

(b) During the starting period, the torque available for accelerating the motor armature is

$$= 1.2 T - T = 0.2 T = 0.2 \times 356 = 71.2 \text{ N-m}$$

$$\text{Now, torque} = I \frac{d\omega}{dt} \quad \therefore 71.2 = 7.5 \times \frac{2\pi \times (20/3)}{dt} \quad \therefore dt = 4.41 \text{ second}$$

### 29.9. Speed of a D.C. Motor

From the voltage equation of a motor (Art. 27.4), we get

$$E_b = V - I_a R_a \quad \text{or} \quad \frac{\Phi Z N}{60} \left( \frac{P}{A} \right) = V - I_a R_a$$

$$\therefore N = \frac{V - I_a R_a}{\Phi} \times \left( \frac{60A}{ZP} \right) \text{ r.p.m.}$$

$$\text{Now} \quad V - I_a R_a = E_b \quad \therefore N = \frac{E_b}{\Phi} \times \left( \frac{60A}{ZP} \right) \text{ r.p.m. or } N = K \frac{E_b}{\Phi}$$

It shows that speed is directly proportional to back e.m.f.  $E_b$  and inversely to the flux  $\Phi$  on  $N \propto E_b/\Phi$ .

#### For Series Motor

Let  $N_1 =$  Speed in the 1st case ;  $I_{a1} =$  armature current in the 1st case

$\Phi_1 =$  flux/pole in the first case

$N_2, I_{a2}, \Phi_2 =$  corresponding quantities in the 2nd case.

Then, using the above relation, we get

$$N_1 \propto \frac{E_{b1}}{\Phi_1} \quad \text{where } E_{b1} = V - I_{a1} R_a ; N_2 \propto \frac{E_{b2}}{\Phi_2} \quad \text{where } E_{b2} = V - I_{a2} R_a$$

$$\therefore \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$$

$$\text{Prior to saturation of magnetic poles ; } \Phi \propto I_a \quad \therefore \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{I_{a1}}{I_{a2}}$$

**For Shunt Motor**

In this case the same equation applies,

$$i.e., \quad \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} \quad \text{If } \Phi_2 = \Phi_1, \text{ then } \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}}.$$

**29.10. Speed Regulation**

The term speed regulation refers to the change in speed of a motor with change in applied load torque, other conditions remaining constant. By change in speed here is meant the change which occurs under these conditions due to inherent properties of the motor itself and not those changes which are affected through manipulation of rheostats or other speed-controlling devices.

The speed regulation is defined *as the change in speed when the load on the motor is reduced from rated value to zero, expressed as percent of the rated load speed.*

$$\therefore \quad \% \text{ speed regulation} = \frac{\text{N.L. speed} - \text{F.L. speed}}{\text{F.L. speed}} \times 100 = \frac{dN}{N} \times 100$$

**29.11. Torque and Speed of a D.C. Motor**

It will be proved that though torque of a motor is admittedly a function of flux and armature current, *yet it is independent of speed*. In fact, it is the speed which depends on torque and not *vice-versa*. It has been proved earlier that

$$N = K \frac{V - I_a R_a}{\phi} = \frac{KE_b}{\Phi} \quad \dots \text{Art. 27.9}$$

Also,  $T_a \propto \Phi I_a \quad \dots \text{Art. 27.7}$

It is seen from above that increase in flux would decrease the speed but increase the armature torque. It cannot be so because torque always tends to produce rotation. If torque increases, motor speed must *increase* rather than *decrease*. The apparent inconsistency between the above two equations can be reconciled in the following way :

Suppose that the flux of a motor is decreased by decreasing the field current. Then, following sequence of events take place :

1. Back e.m.f.  $E_b (= N\Phi/K)$  drops instantly (the speed remains constant because of inertia of the heavy armature).
2. Due to decrease in  $E_b$ ,  $I_a$  is increased because  $I_a = (V - E_b)/R_a$ . Moreover, a small reduction in flux produces a proportionately large increase in armature current.
3. Hence, the equation  $T_a \propto \Phi I_a$ , a small decrease in  $\phi$  is more than counterbalanced by a *large* increase in  $I_a$  with the result that there is a net *increase* in  $T_a$ .
4. This increase in  $T_a$  produces an increase in motor speed.

It is seen from above that with the applied voltage  $V$  held constant, motor speed varies inversely as the flux. However, it is possible to increase flux and, at the same time, increase the speed provided  $I_a$  is held constant as is actually done in a d.c. servomotor.

**Example 29.20.** A 4-pole series motor has 944 wave-connected armature conductors. At a certain load, the flux per pole is 34.6 mWb and the total mechanical torque developed is 209 N-m. Calculate the line current taken by the motor and the speed at which it will run with an applied voltage of 500 V. Total motor resistance is 3 ohm.

(Elect. Engg. AMIETE Sec. A Part II June 1991)

**Solution.**

$$\begin{aligned} T_a &= 0.159 \phi Z I_a \text{ (P/A) N-m} \\ \therefore 209 &= 0.159 \times 34.6 \times 10^{-3} \times 944 \times I_a (4/2); I_a = 20.1 \text{ A} \\ E_a &= V - I_a R_a = 500 - 20.1 \times 3 = 439.7 \text{ V} \end{aligned}$$

Now, speed may be found either by using the relation for  $E_b$  or  $T_a$  as given in Art.

$$E_b = \Phi ZN \times (P/A) \text{ or } 439.7 = 34.6 \times 10^{-3} \times 944 \times N \times 2$$

$$\therefore N = 6.73 \text{ r.p.s. or } \mathbf{382.2 \text{ r.p.m.}}$$

**Example 29.21.** A 250-V shunt motor runs at 1000 r.p.m. at no-load and takes 8A. The total armature and shunt field resistances are respectively 0.2  $\Omega$  and 250  $\Omega$ . Calculate the speed when loaded and taking 50 A. Assume the flux to be constant. (Elect. Engg. A.M.Ae. S.I. June 1991)

**Solution.** Formula used :  $\frac{N}{N_0} = \frac{E_b}{E_{b0}} \times \frac{\Phi_0}{\Phi}$ ; Since  $\Phi_0 = \Phi$  (given);  $\frac{N}{N_0} = \frac{E_b}{E_{b0}}$

$$I_{sh} = 250/250 = 1 \text{ A}$$

$$E_{b0} = V - I_{a0} R_a = 250 - (7 \times 0.2) = 248.6 \text{ V}; E_b = V - I_a R_a = 250 - (49 \times 0.2) = 240.2 \text{ V}$$

$$\therefore \frac{N}{1000} = \frac{240.2}{248.6}; N = \mathbf{9666.1 \text{ r.p.m.}}$$

**Example 29.22.** A d.c. series motor operates at 800 r.p.m. with a line current of 100 A from 230-V mains. Its armature circuit resistance is 0.15  $\Omega$  and its field resistance 0.1  $\Omega$ . Find the speed at which the motor runs at a line current of 25 A, assuming that the flux at this current is 45 per cent of the flux at 100 A. (Electrical Machinery - I, Bangalore Univ. 1986)

**Solution.**  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$ ;  $\Phi_2 = 0.45 \Phi_1$  or  $\frac{\Phi_1}{\Phi_2} = \frac{1}{0.45}$

$$E_{b1} = 230 - (0.15 + 0.1) \times 100 = 205 \text{ V}; E_{b2} = 230 - 25 \times 0.25 = 223.75 \text{ V}$$

$$\frac{N_2}{800} = \frac{223.75}{205} \times \frac{1}{0.45}; N_2 = \mathbf{1940 \text{ r.p.m.}}$$

**Example 29.23.** A 230-V d.c. shunt motor has an armature resistance of 0.5  $\Omega$  and field resistance of 115  $\Omega$ . At no load, the speed is 1,200 r.p.m. and the armature current 2.5 A. On application of rated load, the speed drops to 1,120 r.p.m. Determine the line current and power input when the motor delivers rated load. (Elect. Technology, Kerala Univ. 1988)

**Solution.**  $N_1 = 1200 \text{ r.p.m.}, E_{b1} = 230 - (0.5 \times 2.5) = 228.75 \text{ V}$

$$N_2 = 1120 \text{ r.p.m.}, E_{b2} = 230 - 0.5 I_{a2}$$

Now,  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \therefore \frac{1120}{1200} = \frac{230 - 0.5 I_{a2}}{228.75}; I_{a2} = \mathbf{33 \text{ A}}$

Line current drawn by motor =  $I_{a2} + I_{sh} = 33 + (230/115) = \mathbf{35 \text{ A}}$

Power input at rated load =  $230 \times 35 = \mathbf{8,050 \text{ W}}$

**Example 29.24.** A belt-driven 100-kW, shunt generator running at 300 r.p.m. on 220-V bus-bars continues to run as a motor when the belt breaks, then taking 10 kW. What will be its speed? Given armature resistance = 0.025  $\Omega$ , field resistance = 60  $\Omega$  and contact drop under each brush = 1 V, Ignore armature reaction. (Elect. Machines (E-3) AMIE Sec.C Winter 1991)

**Solution. As Generator** [Fig. 29.12 (a)]

Load current,  $I = 100,000/220 = 454.55 \text{ A}; I_{sh} = 220/60 = 3.67 \text{ A}$

$$I_a = I + I_{sh} = 458.2 \text{ A}; I_a R_a = 458.2 \times 0.025 = 11.45$$

$$E_b = 220 + 11.45 + 2 \times 1 = 233.45 \text{ V}; N_1 = 300 \text{ r.p.m.}$$

Fig. 29.12

**As Motor** [Fig. 29.12 (b)]

$$\begin{aligned} \text{Input line current} &= 100,000/220 = 45.45 \text{ A}; I_{sh} = 220/60 = 3.67 \text{ A} \\ I_a &= 45.45 - 3.67 = 41.78 \text{ A}; I_a R_a = 41.78 \times 0.025 = 1.04 \text{ V}; E_{b2} = 220 - 1.04 - 2 \times 1 = 216.96 \text{ V} \\ \frac{N_2}{N_1} &= \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}; \text{ since } \Phi_1 = \Phi_2 \text{ because } I_{sh} \text{ is constant} \\ \therefore \frac{N_2}{300} &= \frac{216.96}{233.45}; N_2 = 279 \text{ r.p.m.} \end{aligned}$$

**Example 29.25.** A d.c. shunt machine generates 250-V on open circuit at 1000 r.p.m. Effective armature resistance is 0.5 Ω, field resistance is 250 Ω, input to machine running as a motor on no-load is 4 A at 250 V. Calculate speed of machine as a motor taking 40 A at 250 V. Armature reaction weakens field by 4%. **(Electrical Machines-I, Gujarat Univ. 1987)**

**Solution.** Consider the case when the machine runs as a motor on no-load.

$$\text{Now, } I_{sh} = 250/250 = 1 \text{ A}; \text{ Hence, } I_{a0} = 4 - 1 = 3 \text{ A}; E_{b0} = 250 - 0.5 \times 3 = 248.5 \text{ V}$$

It is given that when armature runs at 1000 r.p.m., it generates 250 V. When it generates 248.5 V, it must be running at a speed =  $1000 \times 248.5/250 = 994$  r.p.m.

$$\text{Hence, } N_0 = 994 \text{ r.p.m.}$$

**When Loaded**

$$I_a = 40 - 1 = 39 \text{ A}; E_b = 250 - 39 \times 0.5 = 230.5 \text{ V} \text{ Also, } \Phi_0/\Phi = 1/0.96$$

$$\frac{N}{E} = \frac{E_b}{E_{b0}} \therefore \frac{N}{994} = \frac{230.5}{248.5} \times \frac{1}{0.96} \quad N = 960 \text{ r.p.m.}$$

**Example 29.26.** A 250-V shunt motor giving 14.92 kW at 1000 r.p.m. takes an armature current of 75 A. The armature resistance is 0.25 ohm and the load torque remains constant. If the flux is reduced by 20 percent of its normal value before the speed changes, find the instantaneous value of the armature current and the torque. Determine the final value of the armature current and speed. **(Elect. Engg. AMIETE (New Scheme) 1990)**

**Solution.**  $E_{b1} = 250 - 75 \times 0.25 = 231.25 \text{ V}$ , as in Fig. 29.13.

When flux is reduced by 20%, the back e.m.f. is also reduced instantly by 20% because speed remains constant due to inertia of the heavy armature (Art. 29.11).

$$\therefore \text{Instantaneous value of back e.m.f. } (E_b)_{inst} = 231.25 \times 0.8 = 185 \text{ V}$$

$$(I_a)_{inst} = [V - (E_b)_{inst}]/R_a = (250 - 185)/0.25 = 260 \text{ A}$$

Fig. 29.13

$$\text{Instantaneous value of the torque} = 9.55 \times \frac{(E_b)_{inst} \times (I_a)_{inst}}{N \text{ (in r.p.m.)}}$$

or  $(T_a)_{inst} = 9.55 \times 185 \times 260/1000 = 459 \text{ N-m}$

**Steady Conditions**

Since torque remains constant,  $\Phi_1 I_{a1} = \Phi_2 I_{a2}$

$$I_{a2} = \Phi_1 I_{a1} / \Phi_2 = 75 \times \Phi_1 / 0.8 \Phi_1 = \mathbf{93.7 \text{ A}}$$

$\therefore E_{b2} = 250 - 93.7 \times 0.25 = 226.6 \text{ V}$

Now,  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} = \frac{226.6}{231.25} \times \frac{1}{0.8}; N_2 = 1225 \text{ r.p.m.}$

**Example 29.27.** A 220-V, d.c. shunt motor takes 4 A at no-load when running at 700 r.p.m. The field resistance is 100 Ω. The resistance of armature at standstill gives a drop of 6 volts across armature terminals when 10 A were passed through it. Calculate (a) speed on load (b) torque in N-m and (c) efficiency. The normal input of the motor is 8 kW.

(Electrotechnics-II; M.S. Univ. Baroda 1988)

**Solution. (a)**  $I_{sh} = 200/100 = 2 \text{ A}$

F.L. Power input = 8,000 W; F.L. line current = 8,000/200 = 40 A

$$I_a = 40 - 2 = 38 \text{ A}; R_a = 6/10 = 0.6 \Omega$$

$$E_{b0} = 200 - 2 \times 0.6 = 198.8 \text{ V}; E_b = 200 - 38 \times 0.6 = 177.2 \text{ V}$$

Now,  $\frac{N}{N_0} = \frac{E_b}{E_{b0}}$  or  $\frac{N}{700} = \frac{177.2}{198.8}; N = \mathbf{623.9 \text{ r.p.m.}}$

(b)  $T_a = 9.55 E_b I_a / N = 9.55 \times 177.2 \times 38 / 623.9 = \mathbf{103 \text{ N-m}}$

(c) N.L. power input = 200 × 4 = 800 W; Arm. Cu loss =  $I_a^2 R_a = 2^2 \times 0.6 = 2.4 \text{ W}$

Constant losses = 800 - 2.4 = 797.6 W; F.L. arm. Cu loss =  $38^2 \times 0.6 = 866.4 \text{ W}$

Total F.L. losses = 797.6 + 866.4 = 1664 W; F.L. output = 8,000 - 1664 = 6336 W

F.L. Motor efficiency = 6336/8,000 = 0.792 or **79.2 %**

**Example 29.28.** The input to 230-V, d.c. shunt motor is 11kW. Calculate (a) the torque developed (b) the efficiency (c) the speed at this load. The particulars of the motor are as follows :

No-load current = 5 A; No-load speed = 1150 r.p.m.

Arm. resistance = 0.5 Ω; shunt field resistance = 110 Ω.

(Elect. Technology ; Bombay University 1988)

**Solution.** No-load input = 220 × 5 = 1,100 W;  $I_{sh} = 220/110 = 2\text{A}; I_{ao} = 5 - 2 = 3\text{A}$

No-load armature Cu loss =  $3^2 \times 0.5 = 4.5 \text{ W}$

$\therefore$  Constant losses = 1,100 - 4.5 = 1,095.5 W

**When input is 11 kW.**

Input current = 11,000/220 = 50A ; Armature current = 50 - 2 = **48 A**

Arm. Cu loss =  $48^2 \times 0.5 = 1,152 \text{ W};$

Total loss = Arm. Cu loss + Constant losses = 1152 + 1095.5 = 2248 W

Output = 11,000 - 2,248 = 8,752 W

(b) Efficiency =  $8,752 \times 100 / 11,000 = \mathbf{79.6\%}$

(c) Back e.m.f. at no-load = 220 - (3 × 0.5) = 218.5 V

Back e.m.f. at given load = 220 - (48 × 0.5) = 196 V

$\therefore$  Speed  $N = 1,150 \times 196 / 218.5 = \mathbf{1,031 \text{ r.p.m.}}$

(a) 
$$T_a = 9.55 \times \frac{196 \times 48}{1031} = 87.1 \text{ N-m}$$

**Example 29.29.** The armature circuit resistance of a 18.65 kW 250-V series motor is 0.1 Ω, the brush voltage drop is 3V, and the series field resistance is 0.05. When the motor takes 80 A, speed is 600 r.p.m. Calculate the speed when the current is 100 A.

(Elect. Machines, A.M.I.E. Sec. B, 1993)

**Solution.**

$$E_{b1} = 250 - 80(0.1 + 0.05) - 3 = 235 \text{ V}$$

$$E_{b2} = 250 - 100(0.1 + 0.05) - 3 = 232 \text{ V}$$

Since  $\Phi \propto I_a$ , hence,  $\Phi_1 \propto 80$ ,  $\Phi_2 \propto 100$ ,  $\Phi_1/\Phi_2 = 80/100$

Now 
$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} \text{ or } \frac{N_2}{600} = \frac{232}{235} \times \frac{80}{100}; N_2 = 474 \text{ r.p.m.}$$

**Example 29.30.** A 220-volt d.c. series motor is running at a speed of 800 r.p.m. and draws 100 A. Calculate at what speed the motor will run when developing half the torque. Total resistance of the armature and field is 0.1 ohm. Assume that the magnetic circuit is unsaturated.

(Elect. Machines ; A.M.I.E. Sec. B, 1991)

**Solution.**

$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} = \frac{E_{b2}}{E_{b1}} \times \frac{I_{a1}}{I_{a2}} \quad (\because \Phi \propto I_a)$$

Since field is unsaturated,  $T_a \propto \Phi I_a \propto I_a^2$ .  $(\because T_1 \propto I_{a1}^2 \text{ and } T_2 \propto I_{a2}^2)$

or 
$$T_2/T_1 = (I_{a2}/I_{a1})^2 \text{ or } 1/2 = (I_{a2}/I_{a1})^2; I_{a1} = I_{a2}/\sqrt{2} = 70.7 \text{ A}$$

$$E_{b1} = 220 - 100 \times 0.1 = 210 \text{ V}; E_{b2} = 220 - 0.1 \times 70.7 = 212.9 \text{ V}$$

$\therefore$  
$$\frac{N_2}{800} = \frac{212.9}{210} \times \frac{100}{70.7}; N_2 = 1147 \text{ r.p.m.}$$

**Example 29.31.** A 4-pole d.c. motor runs at 600 r.p.m. on full load taking 25 A at 450 V. The armature is lap-wound with 500 conductors and flux per pole is expressed by the relation.

$$\Phi = (1.7 \times 10^{-2} \times I^{0.5}) \text{ weber}$$

where I is the motor current. If supply voltage and torque are both halved, calculate the speed at which the motor will run. Ignore stray losses.

(Elect. Machines, Nagpur Univ. 1993)

**Solution.** Let us first find  $R_a$

Now 
$$N = \frac{E_b}{Z\Phi} \left( \frac{60 A}{P} \right) \text{ r.p.m.}$$

$\therefore$  
$$600 = \frac{E_b}{1.7 \times 10^{-2} \times 25^{0.5}} \times \frac{60 \times 4}{500 \times 4}$$

$\therefore$  
$$E_b = 10 \times 1.7 \times 10^{-2} \times 5 \times 500 = 425 \text{ V}$$

$$I_a R_a = 450 - 425 = 25 \text{ V}; R_a = 25/25 = 1.0 \Omega$$

**Now in the Ist Case**

$$T_1 \propto \Phi_1 I_1 \quad \therefore T_1 \propto 1.7 \times 10^{-2} \times \sqrt{25} \times 25$$

Similarly 
$$T_2 \propto 1.7 \times 10^{-2} \times \sqrt{1 \times I}; \text{ Now } T_1 = 2T_2$$

$\therefore$  
$$1.7 \times 10^{-2} \times 125 = 1.7 \times 10^{-2} \times I^{3/2} \times 2 \quad \therefore I = (125/2)^{2/3} = 15.75 \text{ A}$$

$$E_{b1} = 425 \text{ V}; E_{b2} = 225 - (15.75 \times 1) = 209.3 \text{ V}$$

Using the relation 
$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}; \text{ we have}$$

$$\frac{N_2}{600} = \frac{209.3}{425} \times \frac{1.7 \times 10^{-2} \times 5}{1.7 \times 10^{-2} \times \sqrt{15.75}}; \quad N_2 = 372 \text{ r.p.m.}$$

### Tutorial Problems 29.2

1. Calculate the torque in newton-metre developed by a 440-V d.c. motor having an armature resistance of  $0.25 \Omega$  and running at 750 r.p.m. when taking a current of 60 A. **[325 N-m]**
2. A 4-pole, lap-connected d.c. motor has 576 conductors and draws an armature current of 10 A. If the flux per pole is 0.02 Wb, calculate the armature torque developed. **[18.3 N-m]**
3. (a) A d.c. shunt machine has armature and field resistances of  $0.025 \Omega$  and  $80 \Omega$  respectively. When connected to constant 400-V bus-bars and driven as a generator at 450 r.p.m., it delivers 120 kW. Calculate its speed when running as a motor and absorbing 120 kW from the same bus-bars.  
(b) Deduce the direction of rotation of this machine when it is working as a motor assuming a clockwise rotation as a generator. **[(a) 435 r.p.m. (b) Clockwise]**
4. The armature current of a series motor is 60 A when on full-load. If the load is adjusted to that this current decreases to 40-A, find the new torque expressed as a percentage of the full-load torque. The flux for a current of 40 A is 70% of that when current is 60 A. **[46%]**
5. A 4-pole, d.c. shunt motor has a flux per pole of 0.04 Wb and the armature is lap-wound with 720 conductors. The shunt field resistance is  $240 \Omega$  and the armature resistance is  $0.2 \Omega$ . Brush contact drop is 1V per brush. Determine the speed of the machine when running (a) as a motor taking 60 A and (b) as a generator supplying 120 A. The terminal voltage in each case is 480 V. **[972 r.p.m. ; 1055 r.p.m.]**
6. A 25-kW shunt generator is delivering full output to 400-V bus-bars and is driven at 950 r.p.m. by belt drive. The belt breaks suddenly but the machine continues to run as a motor taking 25 kW from the bus-bars. At what speed does it run? Take armature resistance including brush contact resistance as  $0.5 \Omega$  and field resistance as  $160 \Omega$ . **[812.7 r.p.m.] (Elect. Technology, Andhra Univ. Apr. 1977)**
7. A 4-pole, d.c. shunt motor has a wave-wound armature with 65 slots each containing 6 conductors. The flux per pole is 20 mWb and the armature has a resistance of  $0.15 \Omega$ . Calculate the motor speed when the machine is operating from a 250-V supply and taking a current of 60 A. **[927 r.p.m.]**
8. A 500-V, d.c. shunt motor has armature and field resistances of  $0.5 \Omega$  and  $200 \Omega$  respectively. When loaded and taking a total input of 25 kW, it runs at 400 r.p.m. Find the speed at which it must be driven as a shunt generator to supply a power output of 25 kW at a terminal voltage of 500 V. **[442 r.p.m.]**
9. A d.c. shunt motor runs at 900 r.p.m. from a 400 V supply when taking an armature current of 25 A. Calculate the speed at which it will run from a 230 V supply when taking an armature current of 15 A. The resistance of the armature circuit is  $0.8 \Omega$ . Assume the flux per pole at 230 V to have decreased to 75% of its value at 400 V. **[595 r.p.m.]**
10. A shunt machine connected to 250-A mains has an armature resistance of  $0.12 \Omega$  and field resistance of  $100 \Omega$ . Find the ratio of the speed of the machine as a generator to the speed as a motor, if line current is 80 A in both cases. **[1.08] (Electrical Engineering-II, Bombay Univ. April. 1977, Madras Univ. Nov. 1978)**
11. A 20-kW d.c. shunt generator delivering rated output at 1000 r.p.m. has a terminal voltage of 500 V. The armature resistance is  $0.1 \Omega$ , voltage drop per brush is 1 volt and the field resistance is  $500 \Omega$ . Calculate the speed at which the machine will run as a motor taking an input of 20 kW from a 500 V d.c. supply. **[976.1 r.p.m.] (Elect. Engg-I Bombay Univ. 1975)**
12. A 4-pole, 250-V, d.c. shunt motor has a lap-connected armature with 960 conductors. The flux per pole is  $2 \times 10^{-2}$  Wb. Calculate the torque developed by the armature and the useful torque in newton-metre when the current taken by the motor is 30A. The armature resistance is  $0.12 \text{ ohm}$  and the field resistance is  $125 \Omega$ . The rotational losses amount to 825 W. **[85.5 N-m ; 75.3 N-m] (Electric Machinery-I, Madras Univ. Nov. 1979)**

### 29.12. Motor Characteristics

The characteristic curves of a motor are those curves which show relationships between the following quantities.

1. **Torque and armature current** *i.e.*  $T_a/I_a$  characteristic. It is known as **electrical characteristic**.
2. **Speed and armature current** *i.e.*  $N/I_a$  characteristic.
3. **Speed and torque** *i.e.*  $N/T_a$  characteristic. It is also known as **mechanical characteristic**. It can be found from (1) and (2) above.

While discussing motor characteristics, the following two relations should always be kept in mind :

$$T_a \propto \Phi I_a \quad \text{and} \quad N \propto \frac{E_b}{\Phi}$$

### 29.13. Characteristics of Series Motors

1.  **$T_a/I_a$  Characteristic.** We have seen that  $T_a \propto \Phi I_a$ . In this case, as field windings also carry the armature current,  $\Phi \propto I_a$  up to the point of magnetic saturation. Hence, before saturation,

$$T_a \propto \Phi I_a \quad \text{and} \quad \therefore T_a \propto I_a^2$$

At light loads,  $I_a$  and hence  $\Phi$  is small. But as  $I_a$  increases,  $T_a$  increases as the square of the current. Hence,  $T_a/I_a$  curve is a parabola as shown in Fig. 29.14. After saturation,  $\Phi$  is almost independent of  $I_a$  hence  $T_a \propto I_a$  only. So the characteristic becomes a straight line. The shaft torque  $T_{sh}$  is less than armature torque due to stray losses. It is shown dotted in the figure. So we conclude that (prior to magnetic saturation) on heavy loads, a series motor exerts a torque proportional to the square of armature current. Hence, in cases where huge starting torque is required for accelerating heavy masses quickly as in hoists and electric trains etc., series motors are used.

Fig. 29.14

Fig. 29.15

Fig. 29.16

2.  **$N/I_a$  Characteristics.** Variations of speed can be deduced from the formula :

$$N \propto \frac{E_b}{\Phi}$$

Change in  $E_b$ , for various load currents is small and hence may be neglected for the time being. With increased  $I_a$ ,  $\Phi$  also increases. Hence, speed varies inversely as armature current as shown in Fig. 29.15.

When load is heavy,  $I_a$  is large. Hence, speed is low (this decreases  $E_b$  and allows more armature current to flow). But when load current and hence  $I_a$  falls to a small value, speed becomes dangerously high. Hence, a series motor should never be started without some mechanical (not belt-driven) load on it otherwise it may develop excessive speed and get damaged due to heavy centrifugal forces so produced. It should be noted that series motor is a variable speed motor.

3.  **$N/T_a$  or mechanical characteristic.** It is found from above that when speed is high, torque is low and **vice-versa**. The relation between the two is as shown in Fig. 29.16.

## 29.14. Characteristics of Shunt Motors

### 1. $T_a/I_a$ Characteristic

Assuming  $\Phi$  to be practically constant (though at heavy loads,  $\phi$  decreases somewhat due to increased armature reaction) we find that  $T_a \propto I_a$ .

Hence, the electrical characteristic as shown in Fig. 29.17, is practically a straight line through the origin. Shaft torque is shown dotted. Since a heavy starting load will need a heavy starting current, shunt motor should never be started on (heavy) load.

### 2. $N/I_a$ Characteristic

If  $\Phi$  is assumed constant, then  $N \propto E_b$ . As  $E_b$  is also practically constant, speed is, for most purposes, constant (Fig. 29.18).

Fig. 29.17

Fig. 29.18

Fig. 29.19

But strictly speaking, both  $E_b$  and  $\Phi$  decrease with increasing load. However,  $E_b$  decreases slightly more than  $\phi$  so that on the whole, there is some decrease in speed. The drop varies from 5 to 15% of full-load speed, being dependent on saturation, armature reaction and brush position. Hence, the actual speed curve is slightly drooping as shown by the dotted line in Fig. 29.18. But, for all practical purposes, shunt motor is taken as a constant-speed motor.

Because there is no appreciable change in the speed of a shunt motor from no-load to full-load, it may be connected to loads which are totally and suddenly thrown off without any fear of excessive speed resulting. Due to the constancy of their speed, shunt motors are suitable for driving shafting, machine tools, lathes, wood-working machines and for all other purposes where an approximately constant speed is required.

**3.  $N/T_a$  Characteristic** can be deduced from (1) and (2) above and is shown in Fig. 29.19.

## 29.15. Compound Motors

These motors have both series and shunt windings. If series excitation helps the shunt excitation *i.e.* series flux is in the **same** direction (Fig. 29.20); then the motor is said to be cumulatively compounded. If on the other hand, series field opposes the shunt field, then the motor is said to be differentially compounded.

The characteristics of such motors lie in between those of shunt and series motors as shown in Fig. 29.21.

### (a) Cumulative-compound Motors

Such machines are used where series characteristics are required and where, in addition,

Compound Motors

the load is likely to be removed totally such as in some types of coal cutting machines or for driving heavy machine tools which have to take sudden cuts quite often. Due to shunt windings, speed will not become excessively high but due to series windings, it will be able to take heavy loads. In conjunction with fly-wheel (functioning as load equalizer), it is employed where there are sudden temporary loads as in rolling mills. The fly-wheel supplies its stored kinetic energy when motor slows down due to sudden heavy load. And when due to the removal of load motor speeds up, it gathers up its kinetic energy.

Fig. 29.20

Compound-wound motors have greatest application with loads that require high starting torques or pulsating loads (because such motors smooth out the energy demand required of a pulsating load). They are used to drive electric shovels, metal-stamping machines, reciprocating pumps, hoists and compressors etc.

**(b) Differential-compound Motors**

Since series field opposes the shunt field, the flux is decreased as load is applied to the motor. This results in the motor speed remaining almost constant or even increasing with increase in load (because,  $N \propto E_b/(\Phi)$ ). Due to this reason, there is a decrease in the rate at which the motor torque increases with load. Such motors are not in common use. But because they can be designed to give an accurately constant speed under all conditions, they find limited application for experimental and research work.

One of the biggest drawback of such a motor is that due to weakening of flux with increases in load, there is a tendency towards speed instability and motor running away unless designed properly.

Fig. 29.21

**Example 29.32.** The following results were obtained from a static torque test on a series motor :

Current (A) :	20	30	40	50
Torque (N - m) :	128.8	230.5	349.8	46.2

Deduce the speed/torque curve for the machine when supplied at a constant voltage of 460 V. Resistance of armature and field winding is 0.5 Ω. Ignore iron and friction losses.

**Solution.** Taking the case when input current is 20 A, we have

$$\text{Motor input} = 460 \times 20 = 9,200 \text{ W}$$

$$\begin{aligned} \text{Field and armature Cu loss} \\ = 20^2 \times 0.5 = 200 \text{ W} \end{aligned}$$

Ignoring iron and friction losses,

$$\text{output} = 9,200 - 200 = 9,000 \text{ W}$$

$$\text{Now, } T_{sh} \times 2\pi N = \text{Output in watts.}$$

$$\therefore 128.8 \times 2\pi \times N = 9,000$$

$$\therefore N = 9,000 / 2\pi \times 128.8$$

$$= 11.12 \text{ r.p.s.} = 667 \text{ r.p.m.}$$

Similar calculations for other values of current are tabulated below :

Current (A)	20	30	40	50
Input (W)	9,200	13,800	18,400	23,000
$I^2R$ loss (W)	200	450	800	1,250
Output (W)	9,200	13,350	17,600	21,850
Speed (r.p.m.)	667	551	480	445
Torque (N-m)	128.8	230.5	349.8	469.2

From these values, the speed/torque curve can be drawn as shown in Fig. 29.22.

Fig. 29.22

**Example 29.33.** A fan which requires 8 h.p. (5.968 kW) at 700 r.p.m. is coupled directly to a d.c. series motor. Calculate the input to the motor when the supply voltage is 500 V, assuming that power required for fan varies as the cube of the speed. For the purpose of obtaining the magnetisation characteristics, the motor was running as a self-excited generator at 600 r.p.m. and the relationship between the terminal voltage and the load current was found to be as follows :

Load current (A)	:	7	10.5	14	27.5
Terminal voltage (V)	:	347	393	434	458

The resistance of both the armature and field windings of the motor is 3.5 Ω and the core, friction and other losses may be assumed to be constant at 450 W for the speeds corresponding to the above range of currents at normal voltage. (I.E.E. London)

**Solution.** Let us, by way of illustration, calculate the speed and output when motor is running off a 500-V supply and taking a current of 7A.

$$\text{Series voltage drop} = 7 \times 3.5 = 24.5 \text{ V}$$

$$\text{Generated or back e.m.f. } E_b = 500 - 24.5 = 475.5 \text{ V}$$

The motor speed is proportional to  $E_b$  for a given current. For a speed of 600 r.p.m. and a current of 7A, the generated e.m.f. is 347 V. Hence,

$$N = 600 \times 475.5 / 347 = 823 \text{ r.p.m.}$$

$$\text{Power to armature} = E_b I_a = 475.5 \times 7 = 3,329 \text{ W}$$

$$\text{Output} = \text{Armature power} - 450 = 3,329 - 450 = 2,879 \text{ W} = \mathbf{2.879 \text{ kW}}$$

$$\text{Power required by the fan at 823 r.p.m. is } = 5.968 \times 823^2 / 700^2 = 9.498 \text{ kW}$$

These calculations are repeated for the other values of current in the following table.

Input current (A)	7	10.5	14	27.5
Series drop (V)	24.5	36.7	49	96.4
Back e.m.f. (V)	475.5	463.3	451	403.6

E.M.F. at 600 r.p.m. (V)	347	393	434	458
Speed $N$ (r.p.m.)	823	707	623	528
Armature power (W)	3329	4870	6310	11,100
Motor output (kW)	2.879	4.420	5.860	10.65
Power required by fan (kW)	9.698	6.146	4.222	2.566

In Fig. 29.23 (i) the motor output in kW and (ii) power required by fan in kW against input current is plotted. Since motor output equals the input to fan, hence the intersection point of these curves gives the value of motor input current under the given conditions.

Input current corresponding to intersection point = 12 A

$\therefore$  Motor input =  $500 \times 12 = 6,000 \text{ W}$

### 29.16. Performance Curves

#### (a) Shunt Motor

In Fig. 29.24 the four essential characteristics of a shunt motor are shown *i.e.* torque, current speed and efficiency, each plotted as a function of motor output power. These are known as the **performance curves** of a motor.

It is seen that shunt motor has a definite no-load speed. Hence, it does not ‘run away’ when load is suddenly thrown off provided the field circuit remains closed. The drop in speed from no-load to full-load is small, hence this motor is usually referred to as **constant speed** motor. The speed for any load within the operating range of the motor can be readily obtained by varying the field current by means of a field rheostat.

The efficiency curve is usually of the same shape for all electric motors and generators. The shape of efficiency curve and the point of maximum efficiency can be varied considerably by the designer, though it is advantageous to have an efficiency curve which is fairly flat, so that there is little change in efficiency between load and 25% overload and to have the maximum efficiency as near to the full load as possible.

It will be seen from the curves, that a certain value of current is required even when output is zero. The motor input under no-load conditions goes to meet the various losses occurring within the machine.

Fig. 29.23

Fig. 29.24

As compared to other motors, a shunt motor is said to have a lower starting torque. But this should not be taken to mean that a shunt motor is incapable of starting a heavy load. Actually, it means that series and compound motors are capable of starting heavy loads with less excess of current inputs over normal values than the shunt motors and that consequently the depreciation on the motor will be relatively less. For example, if twice full load torque is required at start, then shunt motor draws twice the full-load current ( $T_a \propto I_a$  or  $I_a \propto \sqrt{T_a}$ ) whereas series motor draws only approximately one and a half times the full load current ( $T_a \propto I_a^2$  or  $I_a \propto \sqrt{T_a}$ ).

The shunt motor is widely used with loads that require essentially constant speed but where high starting torques are not needed. Such loads include centrifugal pumps, fans, winding reels conveyors and machine tools etc.

**(b) Series Motor**

The typical performance curves for a series motor are shown in Fig. 29.25.

It will be seen that drop in speed with increased load is much more prominent in series motor than in a shunt motor. Hence, a series motor is not suitable for applications requiring a substantially constant speed.

For a given current input, the starting torque developed by a series motor is greater than that developed by a shunt motor. Hence, series motors are used where huge starting torques are necessary *i.e.* for street cars, cranes, hoists and for electric-railway operation. In addition to the huge starting torque, there is another unique characteristic of series motors which makes them especially desirable for traction work *i.e.* when a load comes on a series motor, it responds by decreasing its speed (and hence,  $E_b$ ) and supplies the increased torque with a small increase in current. On the other hand a shunt motor under the same conditions would hold its speed nearly constant and would supply the required increased torque with a large increase of input current. Suppose that instead of a series motor, a shunt motor is used to drive a street car. When the car ascends a grade, the shunt motor maintains the speed for the car at approximately the same value it had on the level ground, but the motor tends to take an excessive current. A series motor, however, automatically slows down on such a grade because of increased current demand, and so it develops more torque at reduced speed. The drop in speed permits the motor to develop a large torque with but a moderate increase of power. Hence, under the same load conditions, rating of the series motor would be less than for a shunt motor.

Fig. 29.25

### 29.17. Comparison of Shunt and Series Motors

#### (a) Shunt Motors

The different characteristics have been discussed in Art. 29.14. It is clear that

- (a) speed of a shunt motor is sufficiently constant.
- (b) for the same current input, its starting torque is not a high as that of series motor. Hence, it is used.
  - (i) When the speed has to be maintained approximately constant from N.L. to F.L. *i.e.* for driving a line of shafting etc.
  - (ii) When it is required to drive the load at various speeds, any one speed being kept constant for a relatively long period *i.e.* for individual driving of such machines as lathes. The shunt regulator enables the required speed control to be obtained easily and economically.

Shunt Motors

#### Summary of Applications

Type of motor	Characteristics	Applications
Shunt	Approximately constant speed Adjustable speed Medium starting torque (Up to 1.5 F.L. torque)	For driving constant speed line shafting Lathes Centrifugal pumps Machine tools Blowers and fans Reciprocating pumps
Series	Variable speed Adjustable varying speed High Starting torque	For traction work <i>i.e.</i> Electric locomotives Rapid transit systems Trolley, cars etc. Cranes and hoists Conveyors
Comulative Compound	Variable speed Adjustable varying speed High starting torque	For intermittent high torque loads For shears and punches Elevators Conveyors Heavy planers Heavy planers Rolling mills; Ice machines; Printing presses; Air compressors

#### (b) Series Motors

The operating characteristics have been discussed in Art 29.13. These motors

1. have a relatively huge starting torques.
2. have good accelerating torque.
3. have low speed at high loads and dangerously high speed at low loads.

Hence, such motors are used

1. when a large starting torque is required *i.e.* for driving hoists, cranes, trams etc.

2. when the motor can be directly coupled to a load such as a fan whose torque increases with speed.

3. if constancy of speed is not essential, then, in fact, the decrease of speed with increase of load has the advantage that the power absorbed by the motor does not increase as rapidly as the torque. For instance, when torque is doubled, the power approximately increases by about 50 to 60% only. ( $\therefore I_a \propto \sqrt{T_a}$ ).

4. a series motor should not be used where there is a possibility of the load decreasing to a very small value. Thus, it should not be used for driving centrifugal pumps or for a belt-drive of any kind.

### 29.18. Losses and Efficiency

The losses taking place in the motor are the same as in generators. These are (i) Copper losses (ii) Magnetic losses and (iii) Mechanical losses.

The condition for maximum power developed by the motor is

$$I_a R_a = V/2 = E_b$$

The condition for maximum efficiency is that armature Cu losses are equal to constant losses. (Art. 26.39).

### 29.19. Power Stages

The various stages of energy transformation in a motor and also the various losses occurring in it are shown in the flow diagram of Fig. 29.26.

Overall or commercial efficiency  $\eta_c = \frac{C}{A}$ , Electrical efficiency  $\eta_e = \frac{B}{A}$ , Mechanical efficiency  $\eta_m = \frac{C}{B}$ .

The efficiency curve for a motor is similar in shape to that for a generator (Art. 24.35).

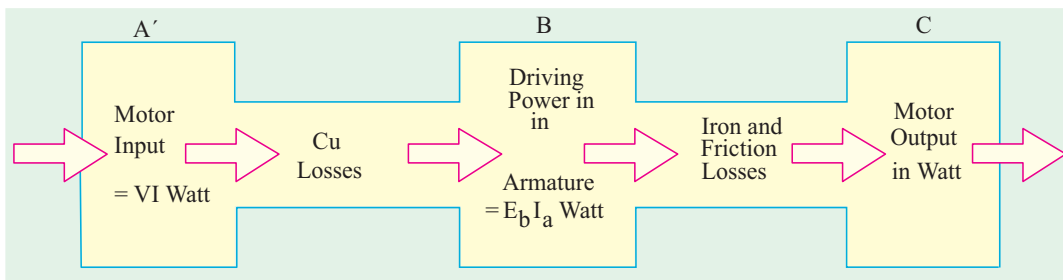

Fig. 29.26

It is seen that  $A - B =$  copper losses and  $B - C =$  iron and friction losses.

**Example 29.34.** One of the two similar 500-V shunt machines A and B running light takes 3 A. When A is mechanically coupled to B, the input to A is 3.5 A with B unexcited and 4.5 A when B is separately-excited to generate 500 V. Calculate the friction and windage loss and core loss of each machine. (Electric Machinery-I, Madras Univ. 1985)

**Solution.** When running light, machine input is used to meet the following losses (i) armature Cu loss (ii) shunt Cu loss (iii) iron loss and (iv) mechanical losses i.e. friction and windage losses. Obviously, these no-load losses for each machine equal  $500 \times 3 = 1500$  W.

**(a) With B unexcited**

In this case, only mechanical losses take place in  $B$ , there being neither Cu loss nor iron-loss because  $B$  is unexcited. Since machine  $A$  draws 0.5 A more current.

Friction and windage loss of  $B = 500 \times 0.5 = 250 \text{ W}$

**(b) With B excited**

In this case, both iron losses as well as mechanical losses take place in machine  $B$ . Now, machine  $A$  draws,  $4.5 - 3 = 1.5 \text{ A}$  more current.

Iron and mechanical losses of  $B = 1.5 \times 500 = 750 \text{ W}$

Iron losses of  $B = 750 - 250 = 500 \text{ W}$

**Example 29.35.** A 220 V shunt motor has an armature resistance of 0.2 ohm and field resistance of 110 ohm. The motor draws 5 A at 1500 r.p.m. at no load. Calculate the speed and shaft torque if the motor draws 52 A at rated voltage. **(Elect. Machines Nagpur Univ. 1993)**

**Solution.**

$$\begin{aligned} I_{sh} &= 220/110 = 2 \text{ A}; I_{a1} = 5 - 2 = 3 \text{ A}; I_{a2} = 52 - 2 = 50 \text{ A} \\ E_{b1} &= 220 - 3 \times 0.2 = 219.4 \text{ V}; E_{b2} = 220 - 50 \times 0.2 = 210 \text{ V} \\ \frac{N_2}{1500} &= \frac{210}{219.4}; N_2 = 1436 \text{ r.p.m. } (\Phi_1 = \Phi_2) \end{aligned}$$

For finding the shaft torque, we will find the motor output when it draws a current of 52 A. First we will use the no-load data for finding the constant losses of the motor.

$$\text{No load motor input} = 220 \times 5 = 1100 \text{ W}; \text{Arm. Cu loss} = 3^2 \times 0.2 = 2 \text{ W}$$

$$\therefore \text{Constant or standing losses of the motor} = 1100 - 2 = 1098$$

$$\text{When loaded, arm. Cu loss} = 50^2 \times 0.2 = 500 \text{ W}$$

$$\text{Hence, total motor losses} = 1098 + 500 = 1598 \text{ W}$$

$$\text{Motor input on load} = 220 \times 52 = 11,440 \text{ W}; \text{output} = 11,440 - 1598 = 9842 \text{ W}$$

$$\therefore T_{sh} = 9.55 \times \text{output}/N = 9.55 \times 9842/1436 = 65.5 \text{ N-m}$$

**Example 29.36.** 250 V shunt motor on no load runs at 1000 r.p.m. and takes 5 amperes. Armature and shunt field resistances are 0.2 and 250 ohms respectively. Calculate the speed when loaded taking a current of 50 A. The armature reaction weakens the field by 3%. **(Elect. Engg.-I Nagpur Univ. 1993)**

**Solution.**

$$\begin{aligned} I_{sh} &= 250/250 = 1 \text{ A}; I_{a1} = 5 - 1 = 4 \text{ A}; I_{a2} = 50 - 1 = 49 \text{ A} \\ E_{b1} &= 250 - 4 \times 0.2 = 249.2 \text{ V}; E_{b2} = 250 - 49 \times 0.2 = 240.2 \text{ V} \\ \frac{N_2}{1000} &= \frac{240.2}{249.2} \times \frac{\Phi_1}{0.97 \Phi_1}; N_2 = 944 \text{ r.p.m.} \end{aligned}$$

**Example 29.37.** A 500 V d.c. shunt motor takes a current of 5 A on no-load. The resistances of the armature and field circuit are 0.22 ohm and 250 ohm respectively. Find (a) the efficiency when loaded and taking a current of 100 A (b) the percentage change of speed. State precisely the assumptions made. **(Elect. Engg.-I, M.S. Univ. Baroda 1987)**

**Solution. No-Load condition**

$$I_{sh} = 500/250 = 2 \text{ A}; I_{a0} = 5 - 2 = 3 \text{ A}; E_{b0} = 500 - (3 \times 0.22) = 499.34 \text{ V}$$

$$\text{Arm. Cu loss} = 3^2 \times 0.22 = 2 \text{ W}; \text{Motor input} = 500 \times 5 = 2500 \text{ W}$$

$$\text{Constant losses} = 2500 - 2 = 2498 \text{ W}$$

It is assumed that these losses remain constant under all load conditions.

**Load condition**

$$(a) \text{ Motor current} = 100 \text{ A}; I_a = 100 - 2 = 98 \text{ A}; E_b = 500 - (98 \times 0.22) = 478.44 \text{ V}$$

$$\begin{aligned} \text{Arm. Cu loss} &= 98^2 \times 0.22 = 2110 \text{ W, Total losses} = 2110 + 2498 = 4608 \text{ W} \\ \text{Motor input} &= 500 \times 100 = 50,000 \text{ W, Motor output} = 50,000 - 4,608 = 45,392 \text{ W} \\ \text{Motor } \eta &= 45,392/50,000 = 0.908 \text{ or } \mathbf{90.8\%} \\ \frac{N}{N_0} &= \frac{E_b}{E_{b0}} = \frac{478.44}{499.34} \text{ or } \frac{N - N_0}{N_0} = \frac{-20.9}{499.34} = -0.0418 \text{ or } \mathbf{-4.18\%} \end{aligned}$$

**Example 29.38.** A 250 V d.c. shunt motor runs at 1000 r.p.m. while taking a current of 25 A. Calculate the speed when the load current is 50 A if armature reaction weakens the field by 3%. Determine torques in both cases.

$$R_a = 0.2 \text{ ohm} ; R_f = 250 \text{ ohms}$$

Voltage drop per brush is 1 V. (Elect. Machines Nagpur Univ. 1993)

**Solution.**

$$\begin{aligned} I_{sh} &= 250/250 = 1 \text{ A}; I_{a1} = 25 - 1 = 24 \text{ A} \\ E_{bh} &= 250 - \text{arm. drop} - \text{brush drop} \\ &= 250 - 24 \times 0.2 - 2 = 243.2 \text{ V} \\ I_{a2} &= 50 - 1 = 49 \text{ A}; E_{b2} = 250 - 49 \times 0.2 - 2 = 238.2 \text{ V} \\ \frac{N_2}{1000} &= \frac{238.2}{243.2} \times \frac{\Phi_1}{0.97 \Phi_1}; N_2 = 1010 \text{ r.p.m.} \\ T_{a1} &= 9.55 E_{b1} I_{a1}/N_1 = 9.55 \times 243.2 \times 24/1000 = 55.7 \text{ N-m} \\ T_{a2} &= 9.55 \times 238.2 \times 49/1010 = 110.4 \text{ r.p.m.} \end{aligned}$$

**Example 29.39.** A d.c. shunt machine while running as generator develops a voltage of 250 V at 1000 r.p.m. on no-load. It has armature resistance of 0.5 Ω and field resistance of 250 Ω. When the machine runs as motor, input to it at no-load is 4 A at 250 V. Calculate the speed and efficiency of the machine when it runs as a motor taking 40 A at 250 V. Armature reaction weakens the field by 4 %.

**Solution.**

$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$$

Now, when running as a generator, the machine gives 250 V at 1000 r.p.m. If this machine was running as motor at 1000 r.p.m., it will, obviously, have a back e.m.f. of 250 V produced in its armature. Hence  $N_1 = 1000$  r.p.m. and  $E_{b1} = 250$  V.

When it runs as a motor, drawing 40 A, the back e.m.f. induced in its armature is

$$E_{b2} = 250 - (40 - 1) \times 0.5 = 230.5 \text{ V; Also } \Phi_2 = 0.96 \Phi_1, N_2 = ?$$

Using the above equation we have

$$\frac{N_2}{1000} = \frac{230.5}{250} \times \frac{\Phi_1}{0.96 \Phi_1}; N_2 = \mathbf{960 \text{ r.p.m.}}$$

**Efficiency**

No-load input represents motor losses which consists of

- (a) armature Cu loss =  $I_a^2 R_a$  which is variable.
- (b) constant losses  $W_c$  which consists of (i) shunt Cu loss (ii) magnetic losses and (iii) mechanical losses.

No-load input or total losses =  $250 \times 4 = 1000$  W

Arm. Cu loss =  $I_a^2 R_a = 3^2 \times 0.5 = 4.5$  W,  $\therefore W_c = 1000 - 4.5 = 995.5$  W

When motor draws a line current of 40 A, its armature current is  $(40 - 1) = 39$  A

Arm. Cu loss =  $39^2 \times 0.5 = 760.5$  W; Total losses =  $760.5 + 955.5 = 1756$  W

Input =  $250 \times 40 = 10,000$  W; output =  $10,000 - 1756 = 8,244$  W

$\therefore \eta = 8,244 \times 100/10,000 = \mathbf{82.44\%}$

**Example 29.40.** The armature winding of a 4-pole, 250 V d.c. shunt motor is lap connected. There are 120 slots, each slot containing 8 conductors. The flux per pole is 20 mWb and current taken by the motor is 25 A. The resistance of armature and field circuit are 0.1 and 125  $\Omega$  respectively. If the rotational losses amount to be 810 W find,

(i) gross torque (ii) useful torque and (iii) efficiency. (Elect. Machines Nagpur Univ. 1993)

**Solution.**  $I_{sh} = 250/125 = 2$  A;  $I_a = 25 - 2 = 23$  A;  $E_b = 250 - (23 \times 0.1) = 247.7$  V

$$\text{Now, } E_b = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right) \quad \therefore 247.7 = \frac{20 \times 10^{-3} \times 960 \times N}{60} \left( \frac{4}{4} \right); N = 773 \text{ r.p.m.}$$

(i) Gross torque or armature torque  $T_a = 9.55 \frac{E_b I_a}{N} = 9.55 \times \frac{247.7 \times 23}{773} = 70.4 \text{ N-m}$

(ii) Arm Cu loss =  $23^2 \times 0.1 = 53$  W; Shunt Cu loss =  $250 \times 2 = 500$  W

Rotational losses = 810 W; Total motor losses =  $810 + 500 + 53 = 1363$  W

Motor input =  $250 \times 25 = 6250$  W; Motor output =  $6250 - 1363 = 4887$  W

$T_{sh} = 9.55 \times \text{output}/N = 9.55 \times 4887/773 = 60.4 \text{ N-m}$

(iii) Efficiency =  $4887/6250 = 0.782 = 78.2\%$

**Example 29.41.** A 20-hp (14.92 kW); 230-V, 1150-r.p.m. 4-pole, d.c. shunt motor has a total of 620 conductors arranged in two parallel paths and yielding an armature circuit resistance of 0.2  $\Omega$ . When it delivers rated power at rated speed, it draws a line current of 74.8 A and a field current of 3 A. Calculate (i) the flux per pole (ii) the torque developed (iii) the rotational losses (iv) total losses expressed as a percentage of power. (Electrical Machinery-I, Bangalore Univ. 1987)

**Solution.**  $I_a = 74.8 - 3 = 71.8$  A;  $E_b = 230 - 71.8 \times 0.2 = 215.64$  V

(i) Now,  $E_b = \frac{\Phi ZN}{60} \left( \frac{P}{A} \right); 215.64 = \frac{\Phi \times 620 \times 1150}{60} \left( \frac{4}{2} \right); \Phi = 9 \text{ mWb}$

(ii) Armature Torque,  $T_a = 9.55 \times 215.64 \times 71.8/1150 = 128.8 \text{ N-m}$

(iii) Driving power in armature =  $E_b I_a = 215.64 \times 71.8 = 15,483$  W

Output = 14,920 W; Rotational losses =  $15,483 - 14,920 = 563$  W

(iv) Motor input =  $VI = 230 \times 74.8 = 17,204$  W; Total loss =  $17,204 - 14,920 = 2,284$  W

Losses expressed as percentage of power input =  $2284/17,204 = 0.133$  or 13.3%

**Example 29.42.** A 7.46 kW, 250-V shunt motor takes a line current of 5 A when running light. Calculate the efficiency as a motor when delivering full load output, if the armature and field resistance are 0.5  $\Omega$  and 250  $\Omega$  respectively. At what output power will the efficiency be maximum? Is it possible to obtain this output from the machine? (Electrotechnics-II, M.S. Univ. Baroda 1985)

**Solution. When loaded lightly**

Total motor input (or total no-load losses) =  $250 \times 5 = 1,250$  W

$$I_{sh} = 250/250 = 1 \text{ A} \quad \therefore I_a = 5 - 1 = 4 \text{ A}$$

$$\text{Field Cu loss} = 250 \times 1 = 250 \text{ W; Armature Cu loss} = 4^2 \times 0.5 = 8 \text{ W}$$

$\therefore$  Iron losses and friction losses =  $1250 - 250 - 8 = 992$  W

These losses would be assumed constant.

Let  $I_a$  be the full-load armature current, then armature input is =  $(250 \times I_a)$  W

$$\text{F.L. output} = 7.46 \times 1000 = 7,460 \text{ W}$$

The losses in the armature are :

(i) Iron and friction losses = 992 W

(ii) Armature Cu loss =  $I_a^2 \times 0.05$  W  $\therefore 250 I_a = 7,460 + 992 + I_a^2 \times 0.5$

or  $0.5 I_a^2 - 250 I_a + 8,452 = 0 \quad \therefore I_a = 36.5 \text{ A}$   
 $\therefore$  F.L. input current =  $36.5 + 1 = 37.5 \text{ A}$  ; Motor input =  $250 \times 37.5 \text{ W}$   
 F.L. output =  $7,460 \text{ W}$   
 $\therefore$  F.L. efficiency =  $7460 \times 100 / 250 \times 37.5 = 79.6\%$   
 Now, efficiency is maximum when armature Cu loss equals constant loss.  
*i.e.*  $I_a^2 R_d = I_a^2 \times 0.5 = (1,250 - 8) = 1,242 \text{ W}$  or  $I_a = 49.84 \text{ A}$   
 $\therefore$  Armature input =  $250 \times 49.84 = 12,460 \text{ W}$   
 Armature Cu loss =  $49.84^2 \times 0.5 = 1242 \text{ W}$ ; Iron and friction losses =  $992 \text{ W}$   
 $\therefore$  Armature output =  $12,460 - (1,242 + 992) = 10,226 \text{ W}$   
 $\therefore$  Output power =  $10,226 \text{ W} = 10.226 \text{ kW}$

As the input current for maximum efficiency is beyond the full-load motor current, it is never realised in practice.

**Example 29.43.** A d.c. series motor drives a load, the torque of which varies as the square of the speed. Assuming the magnetic circuit to be remain unsaturated and the motor resistance to be negligible, estimate the percentage reduction in the motor terminal voltage which will reduce the motor speed to half the value it has on full voltage. What is then the percentage fall in the motor current and efficiency? Stray losses of the motor may be ignored.

(Electrical Engineering-III, Pune Univ. 1987)

**Solution.**  $T_a \propto \Phi I_a \propto I_a^2$ . Also,  $T_a \propto N^2$ . Hence  $N^2 \propto I_a^2$  or  $N \propto I_a$

$\therefore N_1 \propto I_{a1}$  and  $N_2 \propto I_{a2}$  or  $N_2/N_1 = I_{a2}/I_{a1}$

Since,  $N_2/N_1 = 1/2 \quad \therefore I_{a2}/I_{a1} = 1/2$  or  $I_{a2} = I_{a1}/2$

Let  $V_1$  and  $V_2$  be the voltages across the motor in the two cases. Since motor resistance is negligible,  $E_{b1} = V_1$  and  $E_{b2} = V_2$ . Also  $\Phi_1 \propto I_{a1}$  and  $\Phi_2 \propto I_{a2}$  or  $\Phi_1/\Phi_2 = I_{a1}/I_{a2} = I_{a1} \times 2/I_{a1} = 2$

Now,  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$  or  $\frac{1}{2} = \frac{V_2}{V_1} \times 2$  or  $\frac{V_2}{V_1} = \frac{1}{4}$

$\therefore \frac{V_1 - V_2}{V_1} = \frac{4 - 1}{4} = 0.75$

$\therefore$  Percentage reduction in voltage =  $\frac{V_1 - V_2}{V_1} \times 100 = 0.75 \times 100 = 75\%$

Percentage change in motor current =  $\frac{I_{a1} - I_{a2}}{I_{a1}} \times 100 = \frac{I_{a1} - I_{a1}/2}{I_{a1}} \times 100 = 50\%$

**Example 29.44.** A 6-pole, 500-V wave-connected shunt motor has 1200 armature conductors and useful flux/pole of 20 mWb. The armature and field resistance are  $0.5 \Omega$  and  $250 \Omega$  respectively. What will be the speed and torque developed by the motor when it draws 20 A from the supply mains? Neglect armature reaction. If magnetic and mechanical losses amount to 900 W, find (i) useful torque (ii) output in kW and (iii) efficiency at this load.

**Solution. (i)**  $I_{sh} = 500/250 = 2 \text{ A} \quad \therefore I_a = 20 - 2 = 18 \text{ A}$

$\therefore E_b = 500 - (18 \times 0.5) = 491 \text{ V}$ ; Now,  $E_b = \frac{\Phi ZN}{60} \times \left(\frac{P}{A}\right)$  volt

$\therefore 491 = \frac{20 \times 10^{-3} \times 1200 \times N}{60} \times \left(\frac{6}{2}\right)$ ;  $N = 410 \text{ r.p.m. (approx.)}$

Now  $T_a = 9.55 \frac{E_b I_a}{N} = 9.55 \frac{491 \times 18}{410} = 206 \text{ N - m}$

$$\begin{aligned} \text{Armature Cu loss} &= 18^2 \times 0.5 = 162 \text{ W}; \text{ Field Cu loss} = 500 \times 2 = 1000 \text{ W} \\ \text{Iron and friction loss} &= 900 \text{ W}; \text{ Total loss} = 162 + 1000 + 900 = 2,062 \text{ W} \\ \text{Motor input} &= 500 \times 20 = 10,000 \text{ W} \end{aligned}$$

- (i)  $T_{sh} = 9.55 \times \frac{7938}{410} = 184.8 \text{ N - m}$   
 (ii) Output = 10,000 – 2062 = **7,938 kW**  
 (iii)  $\% \eta = \frac{\text{Output}}{\text{Input}} \times 100 = \frac{7,938 \times 100}{10,000} = 0.794 = 79.4\%$

**Example 29.45.** A 50-h.p. (37.3 kW), 460-V d.c. shunt motor running light takes a current of 4 A and runs at a speed of 660 r.p.m. The resistance of the armature circuit (including brushes) is 0.3 Ω and that of the shunt field circuit 270 Ω.

Determine when the motor is running at full load

- (i) the current input (ii) the speed. Determine the armature current at which efficiency is maximum. Ignore the effect of armature reaction. **(Elect. Technology Punjab, Univ. 1991)**

**Solution.**  $I_{sh} = 460/270 = 1.7 \text{ A}$ ; Field Cu loss = 460 × 1.7 = 783 W

**When running light**

$$I_a = 4 - 1.7 = 2.3 \text{ A}; \text{ Armature Cu loss} = 2.3^2 \times 0.3 = 1.5 \text{ W (negligible)}$$

$$\text{No-load armature input} = 460 \times 2.3 = 1,058 \text{ W}$$

As armature Cu loss is negligible, hence 1,058 W represents iron, friction and windage losses which will be assumed to be constant.

Let full-load armature input current be  $I_a$ . Then

$$\text{Armature input} = 460 I_a \text{ W}; \text{ Armature Cu loss} = I_a^2 \times 0.3 \text{ W}$$

$$\text{Output} = 37.3 \text{ kW} = 37,300 \text{ W}$$

$$\therefore 460 I_a = 37,300 + 1,058 + 0.3 I_a^2 \text{ or } 0.3 I_a^2 - 460 I_a + 38,358 = 0$$

$$\therefore I_a = 88.5 \text{ A}$$

(i) Current input = 88.5 + 1.7 = **90.2 A**

(ii)  $E_{b1} = 460 - (2.3 \times 0.3) = 459.3 \text{ V}$ ;  $E_{b2} = 460 - (88.5 \times 0.3) = 433.5 \text{ V}$

$$\therefore N_2 = 660 \times 433.5/459.3 = \mathbf{624 \text{ r.p.m.}}$$

For maximum efficiency,  $I_a^2 R_a = \text{constant losses}$  (Art. 24.37)

$$\therefore I_a^2 \times 0.3 = 1058 + 783 = 1,841 \therefore I_a = (1841/0.3)^{1/2} = \mathbf{78.33 \text{ A}}$$

### Tutorial Problems 29.3

- A 4-pole 250-V, d.c. series motor has a wave-wound armature with 496 conductors. Calculate
  - the gross torque
  - the output torque and
  - the speed
  - the efficiency, if the motor current is 50 A

The value of flux per pole under these conditions is 22 mWb and the corresponding iron, friction and windage losses total 810 W. Armature resistance = 0.19 Ω, field resistance = 0.14 Ω.

[(a) **173.5 N-m** (b) **642 r.p.m.** (c) **161.4 N-m** (d) **86.9%**]

- On no-load, a shunt motor takes 5 A at 250 V, the resistances of the field and armature circuits are 250 Ω and 0.1 Ω respectively. Calculate the output power and efficiency of the motor when the total supply current is 81 A at the same supply voltage. State any assumptions made.

[**18.5 kW; 91%**. It is assumed that windage, friction and eddy current losses are independent of the current and speed]

3. A 230 V series motor is taking 50 A. Resistance of armature and series field windings is 0.2  $\Omega$  and 0.1  $\Omega$  respectively. Calculate :
- (a) brush voltage (b) back e.m.f.  
 (c) power wasted in armature (d) mechanical power developed
- [(a) 215 V (b) 205 V (c) 500 W (d) 13.74 h.p.] (10.25 kW)
4. Calculate the shaft power of a series motor having the following data; overall efficiency 83.5%, speed 550 r.p.m. when taking 65 A; motor resistance 0.2  $\Omega$ , flux per pole 25 mWb, armature winding lap with 1200 conductor.  
 (15.66 kW)
5. A shunt motor running on no-load takes 5 A at 200 V. The resistance of the field circuit is 150  $\Omega$  and of the armature 0.1  $\Omega$ . Determine the output and efficiency of motor when the input current is 120 A at 200 V. State any conditions assumed. (89.8%)
6. A d.c. shunt motor with interpoles has the following particulars :  
 Output power ; 8,952 kW, 440-V, armature resistance 1.1  $\Omega$ , brush contact drop 2 V, interpole winding resistance 0.4  $\Omega$  shunt resistance 650  $\Omega$ , resistance in the shunt regulator 50  $\Omega$ . Iron and friction losses on full-load 450 W. Calculate the efficiency when taking the full rated current of 24 A.  
 (85%)
7. A d.c. series motor on full-load takes 50 A from 230 V d.c. mains. The total resistance of the motor is 0.22  $\Omega$ . If the iron and friction losses together amount to 5% of the input, calculate the power delivered by the motor shaft. Total voltage drop due to the brush contact is 2 A. (10.275 kW)
8. A 2-pole d.c shunt motor operating from a 200 V supply takes a full-load current of 35 A, the no-load current being 2 A. The field resistance is 500  $\Omega$  and the armature has a resistance of 0.6  $\Omega$ . Calculate the efficiency of the motor on full-load. Take the brush drop as being equal to 1.5 V per brush arm. Neglect temperature rise.  
 [Rajiv Gandhi Tech. Univ. Bhopal,2000] (82.63%)

### OBJECTIVE TESTS – 29

- In a d.c. motor, unidirectional torque is produced with the help of  
 (a) brushes (b) commutator  
 (c) end-plates (d) both (a) and (b)
- The counter e.m.f. of a d.c. motor  
 (a) often exceeds the supply voltage  
 (b) aids the applied voltage  
 (c) helps in energy conversion  
 (d) regulates its armature voltage
- The normal value of the armature resistance of a d.c. motor is  
 (a) 0.005 (b) 0.5  
 (c) 10 (d) 100  
 (Grad. I.E.T.E. June 1987)
- The  $E_b/V$  ratio of a d.c. motor is an indication of its  
 (a) efficiency (b) speed regulation  
 (c) starting torque (d) Running Torque  
 (Grad. I.E.T.E. June 1987)
- The mechanical power developed by the armature of a d.c. motor is equal to  
 (a) armature current multiplied by back e.m.f.  
 (b) power input minus losses  
 (c) power output multiplied by efficiency  
 (d) power output plus iron losses
- The induced e.m.f. in the armature conductors of a d.c. motor is  
 (a) sinusoidal (b) trapezoidal  
 (c) rectangular (d) alternating
- A d.c. motor can be looked upon as d.c. generator with the power flow  
 (a) reduced (b) reversed  
 (c) increased (d) modified
- In a d.c. motor, the mechanical output power actually comes from  
 (a) field system  
 (b) air-gap flux  
 (c) back e.m.f.  
 (d) electrical input power
- The maximum torque of d.c. motors is limited by  
 (a) commutation (b) heating

- (c) speed (d) armature current
10. Which of the following quantity maintains the same direction whether a d.c. machine runs as a generator or as a motor ?  
 (a) induced e.m.f. (b) armature current  
 (c) field current (d) supply current
11. Under constant load conditions, the speed of a d.c. motor is affected by  
 (a) field flux (b) armature current  
 (c) back e.m.f. (d) both (b) and (c)
12. It is possible to increase the field flux and, at the same time, increase the speed of a d.c. motor provided its ..... is held constant.  
 (a) applied voltage  
 (b) torque  
 (c) Armature circuit resistance  
 (d) armature current
13. The current drawn by a 120 - V d.c. motor of armature resistance  $0.5 \Omega$  and back e.m.f. 110 V is ..... ampere.  
 (a) 20 (b) 240  
 (c) 220 (d) 5
14. The shaft torque of a d.c. motor is less than its armature torque because of ..... losses.  
 (a) copper (b) mechanical  
 (c) iron (d) rotational
15. A d.c. motor develops a torque of 200 N-m at 25 rps. At 20 rps it will develop a torque of ..... N-m.  
 (a) 200 (b) 160  
 (c) 250 (d) 128
16. Neglecting saturation, if current taken by a series motor is increased from 10 A to 12 A, the percentage increase in its torque is ..... percent  
 (a) 20 (b) 44  
 (c) 30.5 (d) 16.6
17. If load on a d.c. shunt motor is increased, its speed is decreased due primarily to  
 (a) increase in its flux  
 (b) decrease in back e.m.f.  
 (c) increase in armature current  
 (d) increase in brush drop
18. If the load current and flux of a d.c. motor are held constant and voltage applied across its armature is increased by 10 per cent, its speed will  
 (a) decrease by about 10 per cent  
 (b) remain unchanged  
 (c) increase by about 10 per cent  
 (d) increase by 20 per cent.
19. If the pole flux of a d.c. motor approaches zero, its speed will  
 (a) approach zero  
 (b) approach infinity  
 (c) no change due to corresponding change in back e.m.f.  
 (d) approach a stable value somewhere between zero and infinity.
20. If the field circuit of a loaded shunt motor is suddenly opened  
 (a) it would race to almost infinite speed  
 (b) it would draw abnormally high armature current  
 (c) circuit breaker or fuse will open the circuit before too much damage is done to the motor  
 (d) torque developed by the motor would be reduced to zero.
21. Which of the following d.c. motor would be suitable for drives requiring high starting torque but only fairly constant speed such as crushers ?  
 (a) shunt (b) series  
 (c) compound (d) permanent magnet
22. A d.c. shunt motor is found suitable to drive fans because they require  
 (a) small torque at start up  
 (b) large torque at high speeds  
 (c) practically constant voltage  
 (d) both (a) and (b)
23. Which of the following load would be best driven by a d.c. compound motor ?  
 (a) reciprocating pump  
 (b) centrifugal pump  
 (c) electric locomotive  
 (d) fan
24. As the load is increased, the speed of a d.c. shunt motor  
 (a) increases proportionately  
 (b) remains constant  
 (c) increases slightly  
 (d) reduces slightly
25. Between no-load and full-load, ..... motor develops the *least* torque  
 (a) series  
 (b) shunt  
 (c) cumulative compound  
 (d) differential compound

26. The  $T_d/I_a$  graph of a d.c. series motor is a  
 (a) parabola from no-load to overload  
 (b) straight line throughout  
 (c) parabola throughout  
 (d) parabola upto full-load and a straight line at overloads.
27. As compared to shunt and compound motors, series motor has the highest torque because of its comparatively ..... at the start.  
 (a) lower armature resistance  
 (b) stronger series field  
 (c) fewer series turns  
 (d) larger armature current
28. Unlike a shunt motor, it is difficult for a series motor to stall under heavy loading because  
 (a) it develops high overload torque  
 (b) its flux remains constant  
 (c) it slows down considerably  
 (d) its back e.m.f. is reduced to almost zero.
29. When load is removed, ..... motor will run at the **highest** speed.  
 (a) shunt  
 (b) cumulative-compound  
 (c) differential compound  
 (d) series
30. A series motor is best suited for driving  
 (a) lathes  
 (b) cranes and hoists  
 (c) shears and punches  
 (d) machine tools
31. A 220 V shunt motor develops a torque of 54 N-m at armature current of 10 A. The torque produced when the armature current is 20 A, is  
 (a) 54 N-m (b) 81 N-m  
 (c) 108 N-m (d) None of the above  
*(Elect. Machines, A.M.I.E. Sec. B, 1993)*
32. The d.c. series motor should never be switched on at no load because  
 (a) the field current is zero  
 (b) The machine does not pick up  
 (c) The speed becomes dangerously high  
 (d) It will take too long to accelerate.  
*(Grad. I.E.T.E. June 1988)*
33. A shunt d.c. motor works on a.c. mains  
 (a) unsatisfactorily (b) satisfactorily  
 (c) not at all (d) none of the above  
*(Elect. Machines, A.M.I.E. Sec. B, 1993)*
34. A 200 V, 10 A motor could be rewound for 100 V, 20 A by using ..... as many turns per coil of wire, having ..... the cross-sectional area.  
 (a) twice, half  
 (b) thrice, one third  
 (c) half, twice  
 (d) four times, one-fourth

### ANSWERS

## Learning Objectives

- Factors Controlling Motor Speed
- Speed Control of Shunt Motors
- Speed Control of Series Motors
- Merits and Demerits of Rheostatic Control Method
- Series-Parallel Control
- Electric Braking
- Electric Braking of Shunt Motor
- Electric Braking of Series Motors
- Electronic Speed control Method for D.C. Motors
- Uncontrolled Rectifiers
- Controlled Rectifiers
- Thyristor Choppers
- Thyristor Inverters
- Thyristor Speed Control of Separately-excited D.C. Motor
- Thyristor Speed Control of D.C. Series Motor
- Full-wave Speed Control of a Shunt Motor
- Thyristor Control of a Shunt Motor
- Thyristor Speed Control of a Series D.C. Motor
- Necessity of a Starter
- Shunt Motor Starter
- Three-point Starter
- Four-point Starter
- Starting and Speed Control of Series Motors
- Grading of Starting Resistance
- Shunt Motors
- Series Motor Starters
- Thyristor Controller Starters

## SPEED CONTROL OF D.C. MOTORS

DC motor speed controller control the speed of any common dc motor rated upto 100 V. It operates on 5V to 15 V.

### 30.1. Factors Controlling Motor Speed

It has been shown earlier that the speed of a motor is given by the relation

$$N = \frac{V - I_a R_a}{Z \Phi} \cdot \left(\frac{A}{P}\right) = K \frac{V - I_a R_a}{\Phi} \text{ r.p.s.}$$

where

$R_a$  = armature circuit resistance.

It is obvious that the speed can be controlled by varying (i) flux/pole,  $\Phi$  (Flux Control) (ii) resistance  $R_a$  of armature circuit (Rheostatic Control) and (iii) applied voltage  $V$  (Voltage Control). These methods as applied to shunt, compound and series motors will be discussed below.

### 30.2. Speed Control of Shunt motors

#### (i) Variation of Flux or Flux Control Method

Fig. 30.1

It is seen from above that  $N \propto 1/\Phi$ . By decreasing the flux, the speed can be increased and *vice versa*. Hence, the name **flux** or **field control** method. The flux of a d.c. motor can be changed by changing  $I_{sh}$  with help of a shunt field rheostat (Fig. 30.1). Since  $I_{sh}$  is relatively small, shunt field rheostat has to carry only a small current, which means  $I^2 R$  loss is small, so that rheostat is small in size. This method is, therefore, very efficient. In non-interpole machine, the speed can be increased by this method in the ratio 2 : 1. Any further weakening of flux  $\Phi$  adversely affects the commutation and hence puts a limit to the maximum speed obtainable with the method. In machines fitted with interpoles, a ratio of maximum to minimum speed of 6 : 1 is fairly common.

**Example 30.1.** A 500 V shunt motor runs at its normal speed of 250 r.p.m. when the armature current is 200 A. The resistance of armature is 0.12 ohm. Calculate the speed when a resistance is inserted in the field reducing the shunt field to 80% of normal value and the armature current is 100 ampere. (Elect. Engg. A.M.A.E. S.I. June 1992)

**Solution.**  $E_{b1} = 500 - 200 \times 0.12 = 476 \text{ V}$ ;  $E_{b2} = 500 - 100 \times 0.12 = 488 \text{ V}$

$$\Phi_2 = 0.8 \Phi_1 ; N_1 = 250 \text{ rpm} ; N_2 = ?$$

Now, 
$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} \text{ or } \frac{N_2}{250} = \frac{488}{476} \times \frac{\Phi_1}{0.8 \Phi_1}, N_2 = 320 \text{ r.p.m.}$$

**Example 30.2.** A 250 volt d.c. shunt motor has armature resistance of 0.25 ohm, on load it takes an armature current of 50 A and runs at 750 r.p.m. If the flux of motor is reduced by 10% without changing the load torque, find the new speed of the motor. (Elect. Eng-II, Pune Univ. 1987)

**Solution.** 
$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$$

Now,  $T_a \propto \Phi I_a$ . Hence  $T_{a1} \propto \Phi_1 I_{a1}$  and  $T_{a2} \propto \Phi_2 I_{a2}$ .

Since  $T_{a1} = T_{a2} \therefore \Phi_1 I_{a1} = \Phi_2 I_{a2}$

Now,  $\Phi_2 = 0.9 \Phi_1 \therefore 50 \Phi_1 = 0.9 \Phi_2 I_{a2} = 0.9 \Phi_1 I_{a2}$ ,  $I_{a2} = 55.6 \text{ A}$

$\therefore E_{b1} = 250 - (50 \times 0.25) = 237.5 \text{ V}$  ;  $E_{b2} = 250 - (55.6 \times 0.25) = 231.1 \text{ V}$

$\therefore \frac{N_2}{750} = \frac{231.1}{237.5} \times \frac{\Phi_1}{0.9 \Phi_1}$  ;  $N_2 = 811 \text{ r.p.m.}$

**Example 30.3.** Describe briefly the method of speed control available for dc motors.

A 230 V d.c. shunt motor runs at 800 r.p.m. and takes armature current of 50 A. Find resistance

to be added to the field circuit to increase speed to 1000 r.p.m. at an armature current of 80 A. Assume flux proportional to field current. Armature resistance = 0.15  $\Omega$  and field winding resistance = 250  $\Omega$ .  
(Elect. Technology, Hyderabad Univ. 1991)

**Solution.**  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} = \frac{E_{b2}}{E_{b1}} \times \frac{I_{sh1}}{I_{sh2}}$  since flux  $\propto$  field current

$E_{b1} = 230 - (50 \times 0.15) = 222.5 \text{ V}; E_{b2} = 230 - (80 \times 0.15) = 218 \text{ V}$

Let  $R_t =$  total shunt resistance = (250 + R) where R is the additional resistance

$I_{sh1} = 230/250 = 0.92 \text{ A}, I_{sh2} = 230/R_t; N_1 = 800 \text{ r.p.m.}; N = 1000 \text{ r.p.m.}$

$\therefore \frac{1000}{800} = \frac{218}{222.5} \times \frac{0.92}{230/R_t}; R_t = 319 \Omega \quad \therefore R = 319 - 250 = 69 \Omega,$

$I_{sh2} = \frac{230}{319} = 0.721$

Ratio of torque in two cases =  $\frac{T_2}{T_1} = \frac{I_{sh2} I_{a2}}{I_{sh1} I_{a1}} = \frac{0.721 \times 80}{0.92 \times 50} = 1.254$

**Example 30.4.** A 250 V, d.c. shunt motor has shunt field resistance of 250  $\Omega$  and an armature resistance of 0.25  $\Omega$ . For a given load torque and no additional resistance included in the shunt field circuit, the motor runs at 1500 r.p.m. drawing an armature current of 20 A. If a resistance of 250  $\Omega$  is inserted in series with the field, the load torque remaining the same, find out the new speed and armature current. Assume the magnetisation curve to be linear.

(Electrical Engineering-I, Bombay Univ. 1987)

**Solution.** In this case, the motor speed is changed by changing the flux.

Now,  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$

Since it is given that magnetisation curve is linear, it means that flux is directly proportional to shunt current. Hence  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{I_{sh1}}{I_{sh2}}$  where  $E_{b2} = V - I_{a2} R_a$  and  $E_{b1} = V - I_{a1} R_a$ .

Since load torque remains the same  $\therefore T_a \propto \Phi_1 I_{a1} \propto \Phi_2 I_{a2}$  or  $\Phi_1 I_{a1} = \Phi_2 I_{a2}$

$\therefore I_{a2} = I_{a1} \times \frac{\Phi_1}{\Phi_2} = I_{a1} \times \frac{I_{sh1}}{I_{sh2}}$

Now,  $I_{sh1} = 250/250 = 1 \text{ A}; I_{sh2} = 250/(250 + 250) = 1/2 \text{ A}$

$\therefore I_{a2} = 20 \times \frac{1}{1/2} = 40 \text{ A} \quad \therefore E_{b2} = 250 - (40 \times 0.25) = 240 \text{ V}$  and

$E_{b1} = 250 - (20 \times 0.25) = 245 \text{ V} \quad \therefore \frac{N_2}{1500} = \frac{240}{245} \times \frac{1}{1/2}$

$\therefore N_2 = 2,930 \text{ r.p.m.}$

**Example 30.5.** A 250 V, d.c. shunt motor has an armature resistance of 0.5  $\Omega$  and a field resistance of 250  $\Omega$ . When driving a load of constant torque at 600 r.p.m., the armature current is 20 A. If it is desired to raise the speed from 600 to 800 r.p.m., what resistance should be inserted in the shunt field circuit? Assume that the magnetic circuit is unsaturated.

(Elect. Engg. AMIETE, June 1992)

**Solution.**  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$

Since the magnetic circuit is unsaturated, it means that flux is directly proportional to the shunt current.

$$\therefore \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{I_{sh1}}{I_{sh2}} \quad \text{where } E_{b2} = V - I_{a2} R_a \text{ and } E_{b1} = V - I_{a1} R_a$$

Since motor is driving at load of constant torque,

$$T_a \propto \Phi_1 I_{a1} \propto \Phi_2 I_{a2} \quad \therefore \quad \Phi_2 I_{a2} = \Phi_1 I_{a1} \quad \text{or} \quad I_{a2} = I_{a1} \times \frac{\Phi_1}{\Phi_2} = I_{a1} \times \frac{I_{sh1}}{I_{sh2}}$$

Now,  $I_{sh1} = 250/250 = 1 \text{ A}$ ;  $I_{sh2} = 250/R_t$   
 where  $R_t$  is the total resistance of the shunt field circuit.

$$\therefore \quad I_{a2} = 20 \times \frac{1}{250/R_t} = \frac{2R_t}{25}; \quad E_{b1} = 250 - (20 \times 0.5) = 240 \text{ V}$$

$$E_{b2} = 250 - \left( \frac{2R_t}{25} \times 0.5 \right) = 250 - (R_t/25) \quad \therefore \quad \frac{800}{600} = \frac{250 - (R_t/25)}{240} \times \frac{1}{250/R_t}$$

$$0.04 R_t^2 - 250 R_t + 80,000 = 0$$

$$\text{or} \quad R_t = \frac{250 \pm \sqrt{62,500 - 12,800}}{0.08} = \frac{27}{0.08} = 337.5 \Omega$$

Additional resistance required in the shunt field circuit =  $337.5 - 250 = 87.5 \Omega$ .

**Example 30.6.** A 220 V shunt motor has an armature resistance of 0.5 Ω and takes a current of 40 A on full-load. By how much must the main flux be reduced to raise the speed by 50% if the developed torque is constant? (Elect. Machines, AMIE, Sec B, 1991)

**Solution.** Formula used is  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$ . Since torque remains constant,

$$\text{Hence} \quad \Phi_1 I_{a1} = \Phi_2 I_{a2} \quad \therefore \quad I_{a2} = I_{a1} \cdot \frac{\Phi_1}{\Phi_2} = 40x \text{ where } x = \frac{\Phi_1}{\Phi_2}$$

$$E_{b1} = 220 - (40 \times 0.5) = 200 \text{ V}; \quad E_{b2} = 220 - (40x \times 0.5) = (220 - 20x) \text{ V}$$

$$\frac{N_2}{N_1} = \frac{3}{2} \quad \dots \text{ given} \quad \therefore \quad \frac{3}{2} = \frac{(220 - 20x)}{200} \times x \quad \therefore \quad x^2 - 11x + 15 = 0$$

$$\text{or} \quad x = \frac{11 \pm \sqrt{121 - 60}}{2} = \frac{11 \pm 7.81}{2} = 9.4^* \quad \text{or} \quad 1.6$$

$$\therefore \quad \frac{\Phi_1}{\Phi_2} = 1.6 \quad \text{or} \quad \frac{\Phi_2}{\Phi_1} = \frac{1}{1.6}$$

$$\therefore \quad \frac{\Phi_1 - \Phi_2}{\Phi_1} = \frac{1.6 - 1}{1.6} = \frac{3}{8} \quad \therefore \quad \text{percentage change in flux} = \frac{3}{8} \times 100 = 37.5\%$$

**Example 30.7.** A 220-V, 10-kW, 2500 r.p.m. shunt motor draws 41 A when operating at rated conditions. The resistances of the armature, compensating winding, interpole winding and shunt field winding are respectively 0.2 Ω, 0.05 Ω, 0.1 Ω and 110 Ω. Calculate the steady-state values of armature current and motor speed if pole flux is reduced by 25%, a 1 Ω resistance is placed in series with the armature and the load torque is reduced by 50%.

**Solution.**  $I_{sh} = 220/110 = 2 \text{ A}$ ;  $I_{a1} = 41 - 2 = 39 \text{ A}$  (Fig. 30.2)

$$T_1 \propto \Phi_1 I_{a1} \text{ and } T_2 \propto \Phi_2 I_{a2}$$

$$\therefore \quad \frac{T_2}{T_1} = \frac{\Phi_2}{\Phi_1} \times \frac{I_{a2}}{I_{a1}}$$

\* This figure is rejected as it does not give the necessary increase in speed.

or  $\frac{1}{2} = \frac{3}{4} \times \frac{I_{a2}}{39} \therefore I_{a2} = 26 \text{ A}$

$E_{b1} = 220 - 39(0.2 + 0.1 + 0.05) = 206.35 \text{ V}$

$E_{b2} = 220 - 26(1 + 0.35) = 184.9 \text{ V}$

Now,  $\frac{N_2}{2500} = \frac{184.9}{206.35} \times \frac{4}{3}; N_2 = 2987 \text{ r.p.m.}$

Fig. 30.2

**Example 30.8.** A 220 V, 15 kW, 850 r.p.m. shunt motor draws 72.2 A when operating at rated condition. The resistances of the armature and shunt field are 0.25 Ω and 100 Ω respectively. Determine the percentage reduction in field flux in order to obtain a speed of 1650 r.p.m. when armature current drawn is 40 A.

**Solution.**

$I_{sh} = 220/100 = 2.2 \text{ A}; I_{a1} = 72.2 - 2.2 = 70 \text{ A}$

$E_{b1} = 220 - 70 \times 0.25 = 202.5 \text{ V}, E_{b2} = 220 - 40 \times 0.25 = 210 \text{ V.}$

Now,  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$  or  $\frac{1650}{850} = \frac{210}{202.5} \times \frac{\Phi_1}{\Phi_2}$

$\therefore \Phi_2 = 0.534 \Phi_1;$

$\therefore$  Reduction in field flux =  $\frac{\Phi_1 - 0.534 \Phi_1}{\Phi_1} \times 100 = 46.6\%.$

**Example 30.9.** A 220 V shunt motor has an armature resistance of 0.5 ohm and takes an armature current of 40 A on a certain load. By how much must the main flux be reduced to raise the speed by 50% if the developed torque is constant? Neglect saturation and armature reaction.

(Elect. Machines, AMIE, Sec B, 1991)

**Solution.**

$T_1 \propto \Phi_1 \times \Phi_1 \rightarrow \Phi_1 I_{a1}$ , and  $T_2 \propto \Phi_2 I_{a2}$  Since,  $T_1 = T_2$

$\therefore \Phi_2 I_{a2} = \Phi_1 I_{a1}$  or  $\Phi_2/\Phi_1 = I_{a1}/I_{a2} = 40/I_{a2}$

$E_{b1} = 220 - 40 \times 0.5 = 200 \text{ V}; E_{b2} = 220 - 0.5 I_{a2}$

Now,  $\frac{E_{b2}}{E_{b1}} = \frac{N_2 \Phi_2}{N_1 \Phi_1}$  or  $\frac{220 - 0.5 I_{a2}}{200} = \frac{1.5 N_1}{N_1} \times \frac{40}{I_{a2}}$

$\therefore I_{a2} - 40 I_{a2} + 24,000 = 0$  or  $I_{a2} = 63.8 \text{ A}$

$\therefore \frac{\Phi_2}{\Phi_1} = \frac{40}{63.8} = 0.627$  or  $\Phi_2 = 0.627 \Phi_1 = 62.7\% \text{ of } \Phi_1$

**Example 30.10.** A d.c. shunt motor takes an armature current of 20 A from a 220 V supply. Armature circuit resistance is 0.5 ohm. For reducing the speed by 50%, calculate the resistance required in the series, with the armature, if

(a) the load torque is constant

(b) the load torque is proportional to the square of the speed. (Sambalpur Univ., 1998)

**Solution.**

$E_{b1} = V - I_a r_a = 220 - 20 \times 0.5 = 210 \text{ V}$

$210 \propto N_1$

(a) Constant Load torque

In a shunt motor, flux remains constant unless there is a change in terminal voltage or there is a change in the field-circuit resistance.

If torque is constant, armature-current then must remain constant.  $I_a = 20 \text{ amp}$

With an external armature-circuit resistor of R ohms,  $20 \times (R + 0.5) = 220 - E_{b2}$

The speed required now is  $0.5 N_1$ .

With constant flux,  $E_b \propto \text{speed}$ . Hence,  $210 \propto N_1$

$$E_{b2} \propto 0.5 N_1, E_{b2} = 105$$

$$R + 0.5 = (220 - 105)/20 = 5.75, \text{ giving } R = \mathbf{5.25 \text{ ohms}}$$

**(b) Load torque is proportional to the square of speed.**

With constant flux, Developed Torque at  $N_1$  r.p.m.  $\propto I_{a1}$

$$T_{m1} \propto 20$$

From the Load Side,  $T_{L1} \propto N_1^2$

Since  $T_{m1} = T_{L1}$

$$20 \propto N_1^2 \quad \dots(a)$$

At 50% speed, Load Torque,  $T_{L2} \propto (0.5 N_1)^2$

For motor torque,  $T_{m2} \propto I_{a2}$

Since  $T_{L2} = T_{m2}, I_{a2} \propto (0.5 N_1)^2 \quad \dots(b)$

From eqn. (a) and (b) above

$$\frac{I_{a2}}{I_{a1}} = 0.25, I_{a2} = 5 \text{ amp}$$

$$\frac{E_{b2}}{E_{b1}} = \frac{220 - I_{a2}(R + 0.5)}{210} = 0.5 N_1$$

$$220 - I_{a2}(R + 0.5) = 0.5 \times 210$$

$$R + 0.5 = \frac{220 - 105}{5} = 23, R = \mathbf{22.5 \text{ ohms}}$$

**Check :** With the concept of armature power output : (applied here for part (b) only as an illustration).

Armature power-output =  $E_b \times I_a = T \times \omega$

When  $T \propto (\text{speed})^2, E_b I_a = k_1 T \omega = K_2 \omega^3$

At  $N_1$  r.p.m.  $210 \times 20 = K_3 N_1^3 \quad \dots(c)$

With constant flux, at half speed

$$E_{b2} = 105$$

$$105 \times I_{a2} = K_3 (0.5 N_1)^3 \quad \dots(d)$$

From eqs. (c) and (d),

$$\frac{105 \times I_{a2}}{210 \times 20} = \frac{0.125 \times N_1^3}{N_1^3}, \text{ giving } I_{a2} = 5 \text{ amp}$$

This gives  $R = \mathbf{22.5 \text{ ohms.}}$

**Example 30.11.** A 250 V shunt motor runs at 1000 r.p.m. at no-load and takes 8 A. The total armature and shunt field resistances are respectively 0.2 ohm, 250 ohm. Calculate the speed when loaded and taking 50 A. Assume the flux to be constant. (Nagpur Univ. Summer 2000)

**Solution.** The current distribution is shown in Fig. 30.3.

At no load,  $I_L = 8 \text{ amp}, I_f = 1 \text{ amp},$

Hence,  $I_a = 7 \text{ amp}$

$$E_{b0} = 250 - 7 \times 0.2 = 248.6 \text{ volts,}$$

$$= K \phi \times 1000$$

$\therefore K \phi = 0.2486$

Fig. 30.3

$$\begin{aligned} \text{At load, } I_a &= 49 \text{ amp} \\ E_{b1} &= 250 - 49 \times 0.2 = 240.2 \\ N_1 &= \frac{240.2}{0.2486} = 966.2 \text{ r.p.m.} \end{aligned}$$

**Notes :** (i) The assumption of constant flux has simplified the issue. Generally, armature reaction tends to weaken the flux and then the speed tends to increase slightly.

(ii) The no load armature current of 7 amp is required to overcome the mechanical losses of motor as well as driven load, at about 1000 r.p.m.

**Example 30.12.** A 240 V d.c. shunt motor has an armature-resistance of 0.25 ohm, and runs at 1000 r.p.m., taking an armature current 40 A. It is desired to reduce the speed to 800 r.p.m.

(i) If the armature current remains the same, find the additional resistance to be connected in series with the armature-circuit.

(ii) If, with the above additional resistance in the circuit, armature current decreases to 20 A, find the speed of the motor. (Bhartiar Univ., November 1997)

**Solution.**  $E_b = 240 - 0.25 \times 40 = 230 \text{ V}, 230 \propto 1000 \quad \dots(a)$

(i) For 800 r.p.m.,  $E_{b2} \propto 800 \quad \dots(b)$

From (a) and (b),  $E_{b2} = \frac{800}{1000} \times 230 = 184$

$240 - (R + 0.25) \times 40 = 184, R = 1.15 \text{ ohm}$

(ii)  $E_{b3} = 240 - 20 (1.40) = 212$

$E_{b3} = \frac{N_3}{1000} \times 230 = 212, N_3 = \frac{212}{230} \times 1000 = 922 \text{ r.p.m.}$

**Example 30.13.** A 7.48 kW, 220 V, 990 r.p.m. shunt motor has a full load efficiency of 88%, the armature resistance is 0.08 ohm and shunt field current is 2 A. If the speed of this motor is reduced to 450 r.p.m. by inserting a resistance in the armature circuit, find the motor output, the armature current, external resistance to be inserted in the armature circuit and overall efficiency. Assume the load torque to remain constant. (Nagpur Univ., November 1998)

**Solution.** With an output of 7.48 kW and an efficiency of 88%, the input power is 8.50 kW. Losses are 1.02 kW.

Input Current =  $85000/220 = 38.64 \text{ A}$

Armature-Current =  $38.64 - 2.00 = 36.64 \text{ A}$

Power Loss in the shunt field circuit =  $220 \times 2 = 440 \text{ W}$

Copper-Loss in armature-circuit =  $36.64^2 \times 0.08 = 107.4 \text{ W}$

No-Load-Loss at 900 r.p.m. =  $1020 - 107.4 - 440 = 473 \text{ W}$

At 900 r.p.m. Back-emf =  $E_{b1} = 200 - (36.64 \times 0.08) = 217.3 \text{ V}$

Motor will run at 450 r.p.m. with flux per pole kept constant, provided the back-emf =  $E_{b2}$

=  $(459/900) \times 217.1 \text{ V} = 108.5 \text{ V}$

There are two simplifying assumptions in this case, which must be stated before further calculations :

1. Load-torque is constant,
2. No Load Losses are constant.

(These statements can be different which leads to variations in the next steps of calculations.)

For constant load-torque, the condition of constant flux per pole results into constant armature current, which is 36.64 A.

With an armature current of 36.64 A, let the external resistance required for this purpose be  $R$ .

$36.64 R = 217.1 - 108.5 = 108.6 \text{ V}, R = 2.964 \text{ ohms}$

**Total Losses**

$$\begin{aligned} \text{Total } i^2r \text{ - loss in armature} &= 36.64^2 \times (2.964 + 0.08) = 4086 \text{ W} \\ \text{Field-copper-loss} + \text{No load loss} &= 440 + 473 = 913 \\ \text{Total Loss} &= 4999 \text{ W} \\ \text{Total Output} &= 8500 - 4999 = 3501 \text{ W} \end{aligned}$$

Hence, Efficiency =  $(3501/8500) \times 100 = 41.2\%$

**(Note :** Because of missing data and clarification while making the statements in the question, there can be variations in the assumption and hence in the final solutions.)

**Example 30.14.** A d.c. shunt motor supplied at 230 V runs at 990 r.p.m. Calculate the resistance required in series with the armature circuit to reduce the speed to 500 r.p.m. assuming that armature current is 25 amp. (Nagpur Univ., November 1997)

**Solution.** It is assumed that armature resistance is to

(a) At 900 r.p.m. :  $E_{b1} = 230 = K \times 900$

(b) At 500 r.p.m. :  $E_{b2} = K \times 500$

Therefore,  $E_{b2} = E_{b1} \times 500/900 = 127.8$  volts

The difference between  $E_{b1}$  and  $E_{b2}$  must be the drop in the external resistance to be added to the armature circuit for the purpose of reducing the speed to 500 r.p.m.

$$\begin{aligned} E_{b1} - E_{b2} &= 25 \times R \\ R &= (230 - 127.8)/25 = 4.088 \text{ ohms.} \end{aligned}$$

**Example 30.15.** A 220 V d.c. shunt motor has an armature resistance of 0.4 ohm and a field circuit resistance of 200 ohms. When the motor is driving a constant-torque load, the armature-current is 20 A, the speed being 600 r.p.m. It is desired to run the motor at 900 r.p.m. by inserting a resistance in the field circuit. Find its value, assuming that the magnetic circuit is not saturated. (Nagpur Univ., November 1996)

**Solution. (i)** At 600 r.p.m.  $i_{f1} = 220/200 = 1.1$  amp

$$E_{b1} = 220 - (20 \times 0.4) = 212 \text{ volts}$$

$$T_L = K_1 \times 1.1 \times 20$$

$$\text{The back e.m.f.} = 212 = K_2 \times 1.1 \times 600$$

or  $K_2 = 212/660 = 0.3212$

(ii) At 900 r.p.m. :  $T_L = K_1 \times i_{f2} \times I_{a2}$

Due to constant load torque,

$$i_{f2} \times I_{a2} = 1.1 \times 20 = 22$$

$$E_{b2} = 220 - (0.4 I_{a2}) = K_2 \times i_{f2} \times 900 = 289 i_{f2}$$

$$220 - (0.4 \times 22/i_{f2}) = 289 i_{f2}$$

Guess for approximate value of  $i_{f2}$  : Neglecting armature -resistance drop and saturation, 50% rise in speed is obtained with proportional decrease in  $i_{f2}$  related by

$$\frac{600}{900} \cong \frac{i_{f2}}{i_{f1}} \text{ giving } i_{f2} \cong 0.73 \text{ amp}$$

[In place of  $i_{f2}$ ,  $I_{a2}$  can be evaluated first. Its guess-work will give  $I_{a2} \cong 1.5 \times 20 \cong 30$  amp]

Continuing with the solution of the equation to evaluate a value of  $i_{f2}$ , accepting that value which is near 0.73 amp, we have  $i_{f2} = 0.71865$ . [Note that other value of  $i_{f2}$ , which is 0.04235, is not acceptable.]. Corresponding  $I_{a2} = 30.6$  amp. Previous shunt field current,  $i_{f1} = 1.1$ ,  $R_{f1} = 200 \Omega$ . New shunt field current,  $i_{f2} = 0.71865$ ,  $R_{f2} = 220/0.71865 = 306 \Omega$ . Final answer is that a resistor of 106 ohms is to be added to the field circuit to run the motor at 900 r.p.m. at constant torque.

**Example 30.16.** A 220 V d.c. shunt motor has an armature resistance of 0.40 ohm and field-resistance of 200 ohms. It takes an armature current of 22 A and runs at 600 r.p.m. It drives a load whose torque is constant. Suggest a suitable method to raise the speed to 900 r.p.m. Calculate the value of the controllable parameter. (Nagpur Univ., April 1998)

**Solution.** At 600 r.p.m.  $I_{a1} = 22$  amp,  $N_1 = 600$  r.p.m.,  $i_{f1} = 220/200 = 1.1$  amp.  
 $E_{b1} = 220 - (22 \times 0.40) = 211.2$  volts.

Let the Load-torque be denoted by  $T_L$ ,  $k_1$  and  $k_2$  in the equations below represent machine constants appearing in the usual emf-equation and torque-equation for the d.c. shunt motor.

$$E_{b1} = 211.2 = k_1 \times i_{f1} \times N_1 = k_1 \times 1.10 \times 600 \quad \text{or} \quad k_1 = 211.2/660 = 0.32$$

$$T_L = k_2 \times i_{f1} \times I_{a1} = k_2 \times 1.10 \times 22$$

Since the load torque will remain constant at 900 r.p.m. also, the corresponding field current ( $= i_{f2}$ ) and armature current ( $= I_{a2}$ ) must satisfy the following relationships :

$$T_L = k_2 i_{f2} I_{a2} = k_2 \times 1.10 \times 22$$

or  $i_{f2} \times I_{a2} = 24.2$

And  $E_{b2} = 220 - (I_{a2} \times 0.40) = k_1 \times i_{f2} \times 900$

$$220 - (I_{a2} \times 0.40) = 0.32 \times (24.2 \times I_{a2}) \times 900$$

(Alternatively, the above equation can also lead to a quadratic in  $i_{f2}$ .)

This leads to a quadratic equation in  $I_{a2}$ .

Guess for  $i_{f2}$  : Approximately, speed of a d.c. shunt motor is inversely proportional to the field current. Comparing the two speeds of 600 and 900 r.p.m., the value of  $i_{f2}$  should be approximately given by

$$i_{f2} \cong i_{f1} \times (600/900) = 0.733 \text{ amp}$$

Guess for  $I_{a2}$  : For approximate conclusions, armature-resistance drop can be ignored. With constant load-torque, armature-power must be proportional to the speed.

$$\frac{\text{Armature-power at 900 r.p.m.}}{\text{Armature-power at 600 r.p.m.}} = \frac{900}{600} = 1.5$$

$$E_{b2} I_{a2} = 1.5 \times E_{b1} I_{a1}$$

Neglecting armature-resistance drops,  $E_{b1} = V$  and  $E_{b2} = V$ .

This gives  $I_{a2} = 1.5 \times 22 = 33$  amps

Thus, out of the two roots for  $i_{f2}$ , that which is close to 0.733 is acceptable. If quadratic equation for  $I_{a2}$  is being handled, that root which is near 33 amp is acceptable.

Continuing with the solution to quadratic equation for  $I_{a2}$ , we have

$$220 - 0.40 I_{a2} = 0.32 \times (24.2 \times I_{a2}) \times 900$$

$$220 - 0.40 I_{a2} = 6969/I_{a2}$$

$$I_{a2}^2 - 550 I_{a2} + 17425 = 0$$

This gives  $I_{a2}$  as **either** 33.75 amp **or** 791.25 amp.

From the reasoning given above, acceptable root corresponds to  $I_{a2} = 33.75$  amp.

Corresponding field current,  $i_{f2} = 24.2/33.75 = 0.717$  amp

Previous field circuit resistance = 200 ohms

New field circuit resistance =  $220/0.717 = 307$  ohms

Hence, additional resistance of 107 ohms must be added to the shunt field circuit to run the motor at 900 r.p.m. under the stated condition of constant Load torque.

**Additional Check :** Exact calculations for proportions of armature-power in two cases will give the necessary check.

$$E_{b2} = 220 - (33.75 \times 0.40) = 206.5$$

As mentioned above, while guessing the value of  $I_{a2}$ , the proportion of armature-power should be 1.5.

$$\frac{E_{b2} I_{a2}}{E_{b1} I_{a1}} = \frac{206.56 \times 33.75}{211.2 \times 22} = 1.50$$

Thus, the results obtained are confirmed.

**Example 30.17.** A 250 V, 25 kW d.c. shunt motor has an efficiency of 85% when running at 1000 r.p.m. on full load. The armature resistance is 0.1 ohm and field resistance is 125 ohms. Find the starting resistance required to limit the starting current to 150% of the rated current.

(Amravati Univ., 1999)

**Solution.**

Output power = 25 kW, at full-load.

$$\text{Input power} = \frac{25,000}{0.85} = 29412 \text{ watts}$$

At Full load, Input Current =  $29412/250 = 117.65$  amp

Field Current =  $250/125 = 2$  amp

F.L. Armature Current =  $117.65 - 2 = 115.65$  amp

Limit of starting current =  $1.50 \times 115.65 = 173.5$  amp

Total resistance in armature circuit at starting

$$= \frac{250}{173.5} = 1.441 \text{ ohms}$$

External resistance to be added to armature circuit

$$= 1.441 - 0.1 = 1.341 \text{ ohm.}$$

### Tutorial Problems 30.1

- A d.c. shunt motor runs at 900 r.p.m. from a 460 V supply when taking an armature current of 25 A. Calculate the speed at which it will run from a 230-V supply when taking an armature current of 15 A. The resistance of the armature circuit is 0.8  $\Omega$ . Assume the flux per pole at 230 V to have decreased to 75% of its value at 460 V. [595 r.p.m.]
- A 250 V shunt motor has an armature resistance of 0.5  $\Omega$  and runs at 1200 r.p.m. when the armature current is 80 A. If the torque remains unchanged, find the speed and armature current when the field is strengthened by 25%. [998 r.p.m. ; 64 A]
- When on normal full-load, a 500 V, d.c. shunt motor runs at 800 r.p.m. and takes an armature current 42 A. The flux per pole is reduced to 75% of its normal value by suitably increasing the field circuit resistance. Calculate the speed of the motor if the total torque exerted on the armature is (a) unchanged (b) reduced by 20%.  
The armature resistance is 0.6  $\Omega$  and the total voltage loss at the brushes is 2 V. [(a) 1,042 r.p.m. (b) 1,061 r.p.m.]
- The following data apply to d.c. shunt motor.  
Supply voltage = 460 V ; armature current = 28 A ; speed = 1000 r.p.m. ; armature resistance = 0.72  $\Omega$ . Calculate (i) the armature current and (ii) the speed when the flux per pole is increased to 120% of the initial value, given that the total torque developed by the armature is unchanged. [(i) 23.33 A (ii) 840 r.p.m.]
- A 100-V shunt motor, with a field resistance of 50  $\Omega$  and armature resistance of 0.5  $\Omega$  runs at a speed of 1,000 r.p.m. and takes a current of 10 A from the supply. If the total resistance of the field circuit is reduced to three quarters of its original value, find the new speed and the current taken from the supply. Assume that flux is directly proportional to field current. [1,089 r.p.m. ; 8.33 A]

6. A 250 V d.c. shunt motor has armature circuit resistance of  $0.5 \Omega$  and a field circuit resistance of  $125 \Omega$ . It drives a load at 1000 r.p.m. and takes 30 A. The field circuit resistance is then slowly increased to  $150 \Omega$ . If the flux and field current can be assumed to be proportional and if the load torque remains constant, calculate the final speed and armature current. **[1186 r.p.m. 33.6 A]**
7. A 250 V, shunt motor with an armature resistance of  $0.5 \Omega$  and a shunt field resistance of  $250 \Omega$  drives a load the torque of which remains constant. The motor draws from the supply a line current of 21 A when the speed is 600 r.p.m. If the speed is to be raised to 800 r.p.m., what change must be affected in the shunt field resistance? Assume that the magnetization curve of the motor is a straight line. **[88  $\Omega$ ]**
8. A 240 V, d.c. shunt motor runs at 800 r.p.m. with no extra resistance in the field or armature circuit, on no-load. Determine the resistance to be placed in series with the field so that the motor may run at 950 r.p.m. when taking an armature current of 20 A. Field resistance =  $160 \Omega$ . Armature resistance =  $0.4 \Omega$ . It may be assumed that flux per pole is proportional to field current. **[33.6  $\Omega$ ]**
9. A shunt-wound motor has a field resistance of  $400 \Omega$  and an armature resistance of  $0.1 \Omega$  and runs off 240 V supply. The armature current is 60 A and the motor speed is 900 r.p.m.; Assuming a straight line magnetization curve, calculate (a) the additional resistance in the field to increase the speed to 1000 r.p.m. for the same armature current and (b) the speed with the original field current of 200 A. **[(a) 44.4  $\Omega$  (b) 842.5 r.p.m.]**
10. A 230 V d.c. shunt motor has an armature resistance of  $0.5 \Omega$  and a field resistance of  $76 \frac{2}{3} \Omega$ . The motor draws a line current of 13 A while running light at 1000 r.p.m. At a certain load, the field circuit resistance is increased by  $38 \frac{1}{3} \Omega$ . What is the new speed of the motor if the line current at this load is 42 A? **[1400 r.p.m.] (Electrical Engg. ; Grad I.E.T.E. Dec. 1986)**
11. A 250 V d.c. shunt motor runs at 1000 r.p.m. and takes an armature current of 25 amp. Its armature resistance is  $0.40 \text{ ohm}$ . Calculate the speed with increased load with the armature current of 50 amp. Assume that the increased load results into flux-weakening by 3%, with respect to the flux in previous loading condition. **(Nagpur Univ., April 1996)**

Hint : (i) First Loading condition :

$$E_{b1} = 250 - 25 \times 0.40 = K_1 \times 1000$$

(ii) Second Loading condition :

$$E_{b2} = 250 - 50 \times 0.40 = 230 K_1 \times (0.97 \phi) \times N_2. \text{ This gives } N_2. \quad \text{[988 r.p.m.]}$$

**(ii) Armature or Rheostatic Control Method**

This method is used when speeds below the no-load speed are required. As the supply voltage is normally constant, the voltage across the armature is varied by inserting a variable rheostat or resistance (called controller resistance) in series with the armature circuit as shown in Fig. 30.4 (a). As controller resistance is increased, p.d. across the armature is decreased, thereby decreasing the armature speed. For a load constant torque, speed is approximately proportional to the p.d. across the armature. From the speed/armature current characteristic [Fig. 30.4 (b)], it is seen that greater the resistance in the armature circuit, greater is the fall in the speed.

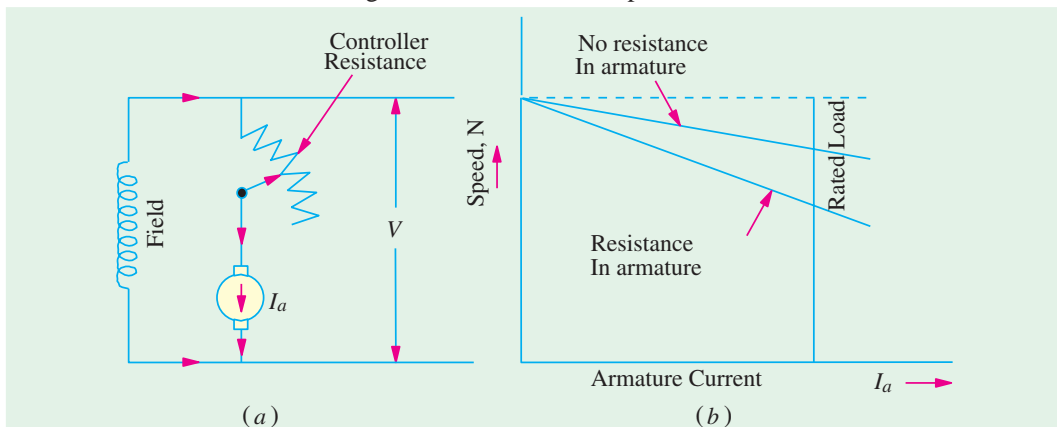

Fig. 30.4

Let  $I_{a1}$  = armature current in the first case  
 $I_{a2}$  = armature current in the second case  
 (If  $I_{a1} = I_{a2}$ , then the load is of constant torque.)  
 $N_1, N_2$  = corresponding speeds,  $V$  = supply voltage

Then  $N_1 \propto V - I_{a1} R_a \propto E_{b1}$

Let some controller resistance of value  $R$  be added to the armature circuit resistance so that its value becomes  $(R + R_a) = R_r$

Then  $N_2 \propto V - I_{a2} R_r \propto E_{b2} \quad \therefore \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}}$

(In fact, it is a simplified form of relation given in Art. 27.9 because here  $\Phi_1 = \Phi_2$ .)

Considering no-load speed, we have  $\frac{N}{N_0} = \frac{V - I_a R_t}{V - I_{a0} R_a}$

Neglecting  $I_{a0} R_a$  with respect to  $V$ , we get

$$N = N_0 \left( 1 - \frac{I_a R_t}{V} \right)$$

It is seen that for a given resistance  $R_t$  the speed is a linear function of armature current  $I_a$  as shown in Fig. 30.5 (a).

The load current for which the speed would be zero is found by putting  $N = 0$  in the above relation.

$$\therefore 0 = N_0 \left( 1 - \frac{I_a R_t}{V} \right) \quad \text{or} \quad I_a = \frac{V}{R_t}$$

This is the maximum current and is known as **stalling** current.

As will be shown in Art. 30.5 (a), this method is very wasteful, expensive and unsuitable for rapidly changing loads because for a given value of  $R_r$ , speed will change with load. A more stable operation can be obtained by using a diverter across the armature in addition to armature control resistance (Fig. 30.5 (b)). Now, the changes in armature current (due to changes in the load torque) will not be so effective in changing the p.d. across the armature (and hence the armature speed).

Fig. 30.5 (a)

Fig. 30.5 (b)

**Example 30.18.** A 200 V d.c. shunt motor running at 1000 r.p.m. takes an armature current of 17.5 A. It is required to reduce the speed to 600 r.p.m. What must be the value of resistance to be inserted in the armature circuit if the original armature resistance is 0.4 Ω? Take armature current to be constant during this process. (Elect. Engg. I Nagpur Univ. 1993)

**Solution.**  $N_1 = 1000$  r.p.m. ;  $E_{b1} = 200 - 17.5 \times 0.4 = 193$  V  
 $R_t =$  total arm. circuit resistance ;  $N_2 = 600$  r.p.m. ;  $E_{b2} = (200 - 17.5 R_t)$

Since  $I_{sh}$  remains constant ;  $\Phi_1 = \Phi_2$   
 $\therefore \frac{600}{1000} = \frac{(200 - 17.5 R_t)}{193}$  ;  $R_t = 4.8 \Omega$

$\therefore$  Additional resistance reqd.  $R = R_t - R_a = 4.8 - 0.4 = 4.4 \Omega$ .

It may be noted that brush voltage drop has not been considered.

**Example 30.19.** A 500 V d.c. shunt motor has armature and field resistances of 1.2 Ω and 500 Ω respectively. When running on no-load, the current taken is 4 A and the speed is 1000 r.p.m. Calculate the speed when motor is fully loaded and the total current drawn from the supply is 26 A. Estimate the speed at this load if (a) a resistance of 2.3 Ω is connected in series with the armature and (b) the shunt field current is reduced by 15%. (Electrical Engg. I, Sd. Patel Univ. 1985)

**Solution.**  $I_{sh} = 500/500 = 1 \text{ A}$  ;  $I_{a1} = 4 - 1 = 3 \text{ A}$   
 $E_{b1} = 500 - (3 \times 1.2) = 496.4 \text{ V}$   $I_{a2} = 26 - 1 = 25 \text{ A}$   
 $E_{b2} = 500 - (25 \times 1.2) = 470 \text{ V}$   $\therefore \frac{N_2}{1000} = \frac{470}{496.4}$  ;  $N_2 = 947 \text{ r.p.m.}$

(a) In this case, total armature circuit resistance =  $1.2 + 2.3 = 3.5 \Omega$

$\therefore E_{b2} = 500 - (25 \times 3.5) = 412.5 \text{ V}$   $\therefore \frac{N_2}{1000} = \frac{412.5}{496.4}$  ;  $N_2 = 831 \text{ r.p.m.}$

(b) When shunt field is reduced by 15%,  $\Phi_2 = 0.85 \Phi_1$  assuming straight magnetisation curve.

$\frac{N_2}{1000} = \frac{412.5}{496.4} \times \frac{1}{0.85}$  ;  $N_2 = 977.6 \text{ r.p.m.}$

**Example 30.20.** A 250-V shunt motor (Fig. 30.6) has an armature current of 20 A when running at 1000 r.p.m. against full load torque. The armature resistance is 0.5 Ω. What resistance must be inserted in series with the armature to reduce the speed to 500 r.p.m. at the same torque and what will be the speed if the load torque is halved with this resistance in the circuit? Assume the flux to remain constant throughout and neglect brush contact drop.

(Elect. Machines AMIE Sec. B Summer 1991)

**Solution.**  $E_{b1} = V - I_{a1} R_a = 250 - 20 \times 0.5 = 240 \text{ V}$

Let  $R_t$  to be total resistance in the armature circuit i.e.  $R_t = R_a + R$ , where  $R$  is the additional resistance.

$\therefore E_{b2} = V - I_{a2} R_t = 250 - 20 R_t$

It should be noted that  $I_{a1} = I_{a2} = 20 \text{ A}$  because torque remains the same and  $\Phi_1 = \Phi_2$  in both cases.

$\therefore \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} = \frac{E_{b2}}{E_{b1}}$  or  $\frac{500}{1000} = \frac{250 - 20 R_t}{240}$

$\therefore R_t = 6.5 \Omega$  ; hence,  $R = 6.5 - 0.5 = 6 \Omega$

Since the load is halved, armature current is also halved because flux remains constant. Hence,  $I_{a3} = 10 \text{ A}$ .

$\therefore \frac{N_3}{1000} = \frac{250 - 10 \times 6.5}{240}$  or  $N_3 = 771 \text{ r.p.m.}$

Fig. 30.6

**Example 30.21.** A 250-V shunt motor with armature resistance of 0.5 ohm runs at 600 r.p.m. on full-load and takes an armature current of 20 A. If resistance of 1.0 ohm is placed in the armature circuit, find the speed at (i) full-load torque (ii) half full-load torque.

(Electrical Machines-II, Punjab Univ. May 1991)

**Solution.** Since flux remains constant, the speed formula becomes  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}}$ .

(i) In the first case, full-load torque is developed.

$N_1 = 600 \text{ r.p.m.}$ ;  $E_{b1} = V - I_{a1} R_{a1} = 250 - 20 \times 0.5 = 240 \text{ V}$

Now,  $T \propto \Phi I_a \propto I_a$  ( $\because \Phi$  is constant)

$\therefore \frac{T_2}{T_1} = \frac{I_{a2}}{I_{a1}}$  Since  $T_2 = T_1$  ;  $I_{a2} = I_{a1} = 20 \text{ A}$

$E_{b2} = V - I_{a2} R_{a2} = 250 - 20 \times 1.5 = 220 \text{ V}$ ,

$N_2 = \frac{N_1 E_{b2}}{E_{b1}} = \frac{600 \times 220}{240}$  ;  $N_2 = 550 \text{ r.p.m.}$

(ii) In this case, the torque developed is half the full-load torque.

$$\frac{T_2}{T_1} = \frac{I_{a2}}{I_{a1}} \quad \text{or} \quad \frac{T_1/2}{T_1} = \frac{I_{a2}}{20}; I_{a2} = 10 \text{ A}; E_{b2} = 250 - 10 \times 1.5 = 235 \text{ V}$$

$$\frac{N_2}{600} = \frac{235}{240}; N_2 = 600 \times \frac{235}{240} = \mathbf{587.5 \text{ r.p.m.}}$$

**Example 30.22.** A 220 V shunt motor with an armature resistance of 0.5 ohm is excited to give constant main field. At full load the motor runs of 500 rev. per minute and takes an armature current of 30 A. If a resistance of 1.0 ohm is placed in the armature circuit, find the speed at (a) full-load torque (b) double full-load torque. (Elect. Machines-I, Nagpur Univ. 1993)

**Solution.** Since flux remains constant, the speed formula becomes  $N_2/N_1 = E_{b2}/E_{b1}$ .

(a) Full-load torque

With no additional resistance in the armature circuit,

$$N_1 = 500 \text{ r.p.m.}; I_{a1} = 30 \text{ A}; E_{b1} = 220 - 30 \times 0.5 = 205 \text{ V}$$

Now,  $T \propto I_a$  (since  $\Phi$  is constant.)  $\therefore \frac{T_2}{T_1} = \frac{I_{a2}}{I_{a1}}$  Since  $T_2 = T_1; I_{a2} = I_{a1} = 30 \text{ A}$

When additional resistance of 1  $\Omega$  is introduced in the armature circuit,

$$E_{b2} = 220 - 30(1 + 0.5) = 175 \text{ V}; N_2 = ? \quad \frac{N_2}{500} = \frac{175}{205}; N_2 = \mathbf{427 \text{ r.p.m.}}$$

(b) Double Full-load Torque

$$\frac{T_2}{T_1} = \frac{I_{a2}}{I_{a1}} \quad \text{or} \quad \frac{2T_1}{T_1} = \frac{I_{a2}}{30}; I_{a2} = 60 \text{ A}$$

$$\therefore E_{b2} = 220 - 60(1 + 0.5) = 130 \text{ V}$$

$$\therefore \frac{N_2}{500} = \frac{130}{205}; N_2 = \mathbf{317 \text{ r.p.m.}}$$

**Example 30.23.** The speed of a 50 h.p (37.3 kW) series motor working on 500 V supply is 750 r.p.m. at full-load and 90 per cent efficiency. If the load torque is made 350 N-m and a 5 ohm resistance is connected in series with the machine, calculate the speed at which the machine will run. Assume the magnetic circuit to be unsaturated and the armature and field resistance to be 0.5 ohm. (Electrical Machinery I, Madras Univ. 1986)

**Solution.** Load torque in the first case is given by

$$T_1 = 37,300/2\pi (750/60) = 474.6 \text{ N-m}$$

$$\text{Input current, } I_{a1} = 37,300/0.9 \times 500 = 82.9 \text{ A}$$

$$\text{Now, } T_2 = 250 \text{ N-m}; I_{a2} = ?$$

In a series motor, before magnetic saturation,

$$T \propto \Phi I_a \propto I_{a2} \quad \therefore T_1 \propto I_{a1}^2 \text{ and } T_2 \propto I_{a2}^2$$

$$\therefore \left(\frac{I_{a2}}{I_{a1}}\right)^2 = \frac{T_2}{T_1} \quad \therefore I_{a2} = 82.9 \times \sqrt{250/474.6} = 60.2 \text{ A}$$

$$\text{Now, } E_{b1} = 500 - (82.9 \times 0.5) = 458.5 \text{ V};$$

$$E_{b2} = 500 - 60.2(5 + 0.5) = 168.9 \text{ V}$$

$$\text{Using } \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{I_{a1}}{I_{a2}}, \text{ we get } \frac{N_2}{750} = \frac{168.9}{458.5} \times \frac{82.9}{60.2} \quad \therefore N_2 = \mathbf{381 \text{ r.p.m.}}$$

**Example 30.24.** A 7.46 kW, 220 V, 900 r.p.m. shunt motor has a full-load efficiency of 88 per cent, an armature resistance of 0.08  $\Omega$  and shunt field current of 2 A. If the speed of this motor is

reduced to 450 r.p.m. by inserting a resistance in the armature circuit, the load torque remaining constant, find the motor output, the armature current, the external resistance and the overall efficiency.

(Elect. Machines, Nagpur Univ. 1993)

**Solution.** Full-load motor input current  $I = 7460/220 \times 0.88 = 38.5$  A

$$\therefore I_{a1} = 38.5 - 2 = 36.5 \text{ A}$$

Now,  $T \propto \Phi I_a$ . Since flux remains constant.

$$\therefore T \propto I_a \quad \therefore T_{a1} \propto I_{a1} \text{ and } T_{a2} \propto I_{a2} \quad \text{or} \quad \frac{T_{a2}}{T_{a1}} = \frac{I_{a2}}{I_{a1}}$$

It is given that  $T_{a1} = T_{a2}$ ; hence  $I_{a1} = I_{a2} = 36.5$  A

$$E_{b1} = 220 - (36.5 \times 0.08) = 217.1 \text{ V}$$

$$E_{b2} = 220 - 36.5 R_t; N_1 = 900 \text{ r.p.m.}; N_2 = 450 \text{ r.p.m.}$$

$$\text{Now, } \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} = \frac{E_{b2}}{E_{b1}} \quad (\because \Phi_1 = \Phi_2)$$

$$\therefore \frac{450}{900} = \frac{220 - 36.5 R_t}{217.1}; R_t = 3.05 \text{ } \Omega$$

$$\therefore \text{External resistance } R = 3.05 - 0.08 = 2.97 \text{ } \Omega$$

For calculating the motor output, it will be assumed that all losses except copper losses vary directly with speed.

Since motor speed is halved, stray losses are also halved in the second case. Let us find their value.

In the first case, motor input =  $220 \times 38.5 = 8,470$  W; Motor output = 7,460 W

Total Cu losses + stray losses =  $8470 - 7460 = 1010$  W

Arm. Cu loss =  $I_{a1}^2 R_a = 36.5^2 \times 0.08 = 107$  W; Field Cu loss =  $220 \times 2 = 440$  W

Total Cu loss =  $107 + 440 = 547$  W  $\therefore$  Stray losses in first case =  $1010 - 547 = 463$  W

Stray losses in the second case =  $463 \times 450/900 = 231$  W

Field Cu loss = 440 W, as before; Arm. Cu loss =  $36.5^2 \times 3.05 = 4,064$  W

Total losses in the 2nd case =  $231 + 440 + 4,064 = 4,735$  W

Input = 8,470 W – as before

Output in the second case =  $8,470 - 4,735 = 3,735$  W

$$\therefore \text{Overall } \eta = 3,735/8,470 = 0.441 \text{ or } 44.1 \text{ per cent}^*$$

**Example 30.25.** A 240 V shunt motor has an armature current of 15 A when running at 800 r.p.m. against F.L. torque. The arm. resistance is 0.6 ohms. What resistance must be inserted in series with the armature to reduce the speed to 400 r.p.m., at the same torque ?

What will be the speed if the load torque is halved with this resistance in the circuit ? Assume the flux to remain constant throughout.

(Elect. Machines-I Nagpur Univ. 1993)

**Solution.** Here,  $N_1 = 800$  r.p.m.,  $E_{b1} = 240 - 15 \times 0.6 = 231$  V

Flux remaining constant,  $T \propto I_a$ . Since torque is the same in both cases,  $I_{a2} = I_{a1} = 15$  A. Let  $R$  be the additional resistance inserted in series with the armature.  $E_{b2} = 240 - 15(R + 0.6)$ ;  $N_2 = 400$  r.p.m.

$$\therefore \frac{400}{800} = \frac{240 - 15(R + 0.6)}{231}; R = 7.7 \text{ } \Omega$$

\* It may be noted that efficiency is reduced almost in the ratio of the two speeds.

**When load torque is halved :**

With constant flux when load torque is halved,  $I_a$  is also halved. Hence,  $I_{a3} = I_{a1}/2 = 15/2 = 7.5$  A

$$\therefore E_{b3} = 240 - 7.5(7.7 + 0.6) = 177.75 \text{ V}; N_3 = ?$$

$$\frac{N_3}{N_1} = \frac{E_{b3}}{E_{b1}} \text{ or } \frac{N_3}{800} = \frac{177.75}{231}; N_3 = \mathbf{614.7 \text{ r.p.m.}}$$

**Example 30.26. (a)** A 400 V shunt connected d.c. motor takes a total current of 3.5 A on no load and 59.5 A at full load. The field circuit resistance is 267 ohms and the armature circuit resistance is 0.2 ohms (excluding brushes where the drop may be taken as 2 V). If the armature reaction effect at 'full-load' weakens the flux per pole by 2 percentage change in speed from no-load to full-load.

**(b)** What resistant must be placed in series with the armature in the machine of (a) if the full-load speed is to be reduced by 50 per cent with the gross torque remaining constant? Assume no change in the flux. **(Electrical Machines, AMIE Sec. B, 1989)**

**Solution. (a)** Shunt current  $I_{sh} = 400/267 = 1.5$  A. At no load,  $I_{a1} = 3.5 - 1.5 = 2$  A,  $E_{b1} = V - I_{a1}R_{ai} - \text{brush drop} = 400 - 2 \times 0.2 - 2 = 397.6$  V. On full-load,  $I_{a2} = 59.5 - 1.5 = 58$  A,  $E_{b2} = 400 - 58 \times 0.2 - 2 = 386.4$  V.

$$\therefore \frac{E_{b1}}{E_{b2}} = \frac{\Phi_1 N_1}{\Phi_2 N_2} \text{ or } \frac{397.6}{386.4} = \frac{\Phi_1 N_1}{0.98 \Phi_1 N_2}; \frac{N_1}{N_2} = 1.0084$$

$$\begin{aligned} \% \text{ change in speed} &= \frac{N_1 - N_2}{N_1} \times 100 \\ &= \left(1 - \frac{1}{1.0084}\right) \times 100 = 0.833 \end{aligned}$$

**(b)** Since torque remains the same,  $I_a$  remains the same, hence  $I_{a3} = I_{a2}$ . Let  $R$  be the resistance connected in series with the armature.

$$\begin{aligned} E_{b3} &= V - I_{a2}(R_a + R) - \text{brush drop} \\ &= 400 - 58(0.2 + R) - 2 = 386.4 - 58R \end{aligned}$$

$$\therefore \frac{E_{b2}}{E_{b3}} = \frac{\Phi_2 N_2}{\Phi_3 N_3} = \frac{N_2}{N_3} \quad (\text{as } \Phi_2 = \Phi_3)$$

$$\frac{386.4}{386.4 - 58R} = \frac{1}{0.5}; R = \mathbf{3.338 \Omega}$$

**Example 30.27.** A d.c. shunt drives a centrifugal pump whose torque varies as the square of the speed. The motor is fed from a 200 V supply and takes 50 A when running at 1000 r.p.m. What resistance must be inserted in the armature circuit in order to reduce the speed to 800 r.p.m.? The armature and field resistance of the motor are 0.1  $\Omega$  and 100  $\Omega$  respectively.

**(Elect. Machines, Allahabad Univ. 1992)**

**Solution.** In general,  $T \propto \Phi I_a$

For shunt motors whose excitation is constant,

$$T \propto I_a \propto N^2, \text{ as given.}$$

$$\therefore I_a \propto N^2. \text{ Now } I_{sh} = 200/100 = 2 \text{ A} \quad \therefore I_{a1} = 50 - 2 = 48 \text{ A}$$

Let  $I_{a2}$  = new armature current at 800 r.p.m.

then  $48 \propto N_1^2 \propto 1000^2$  and  $I_{a2} \propto N_2^2 \propto 800^2$

$$\therefore \frac{I_{a2}}{48} = \left(\frac{800}{1000}\right)^2 = 0.8^2 \quad \therefore I_{a2} = 48 \times 0.64 = 30.72 \text{ A}$$

$$\therefore E_{b1} = 200 - (48 \times 0.1) = 195.2 \text{ V}; E_{b2} = (200 - 30.72 R_t) \text{ V}$$

Now, 
$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \quad \therefore \frac{800}{1000} = \frac{200 - 30.72 R_t}{195.2}, R_t = 1.42 \Omega$$

Additional resistance =  $1.42 - 0.1 = 1.32 \Omega$

**Example 30.28.** A 250 V, 50 h.p. (373 kW) d.c. shunt motor has an efficiency of 90% when running at 1,000 r.p.m. on full-load. The armature and field resistances are 0.1 Ω and 115 Ω respectively. Find

- (a) the net and developed torque on full-load.
- (b) the starting resistance to have the line start current equal to 1.5 times the full-load current.
- (c) the torque developed at starting. (Elect. Machinery-I, Kerala Univ. 1987)

**Solution.** (a)  $T_{sh} = 9.55 \times 37,300/1000 = 356.2 \text{ N-m}$

Input current =  $\frac{37,300}{250 \times 0.9} = 165.8 \text{ A}; I_{sh} = \frac{250}{125} = 2 \text{ A}$

$\therefore I_a = 165.8 - 2 = 163.8 \text{ A}; E_b = 250 - (163.8 \times 0.1) = 233.6 \text{ V}$

$\therefore T_a = 9.55 \frac{233.6 \times 163.8}{1000} = 365.4 \text{ N-m}$

- (b) F.L. input line  $I = 165.8 \text{ A}$ ; Permissible input  $I = 165.8 \times 1.5 = 248.7 \text{ A}$
- Permissible armature current =  $248.7 - 2 = 246.7 \text{ A}$
- Total armature resistance =  $250/246.7 = 1.014 \Omega$
- $\therefore$  Starting resistance required =  $1.014 - 0.1 = 0.914 \Omega$

- (c) Torque developed with 1.5 times the F.L. current would be practically 1.5 times the F.L. torque.
- i.e.  $1.5 \times 365.4 = 548.1 \text{ N-m.}$

**Example 30.29.** A 200 V shunt motor with a shunt resistance of 40 Ω and armature resistance of 0.02 Ω takes a current of 55 A and runs at 595 r.p.m. when there is a resistance of 0.58 Ω in series with armature. Torque remaining the same, what change should be made in the armature circuit resistance to raise the speed to 630 r.p.m. ? Also find

- (i) At what speed will the motor run if the load torque is reduced such that armature current is 15 A.
- (ii) Now, suppose that a diverter of resistance 5 Ω is connected across the armature and series resistance is so adjusted that motor speed is again 595 r.p.m., when armature current is 50 A. What is the value of this series resistance ? Also, find the speed when motor current falls of 15 A again.

**Solution.** The circuit is shown in Fig. 30.7.

Fig. 30.7

Fig. 30.8

$I_{sh} = 200/40 = 5 \text{ A} \quad \therefore I_{a1} = 55 - 5 = 50 \text{ A}$   
 Armature circuit resistance =  $0.58 + 0.02 = 0.6 \Omega$   
 $\therefore E_{b1} = 200 - (50 \times 0.6) = 170 \text{ V}$   
 Since torque is the same in both cases,  $I_{a1} \Phi_1 = I_{a2} \Phi_2$   
 Moreover,  $\Phi_1 = \Phi_2 \quad \therefore I_{a1} = I_{a2} \quad \therefore I_{a2} = 50 \text{ A}$   
 Now  $E_{b1} = 170 \text{ V}, N_1 = 595 \text{ r.p.m.}, N_2 = 630 \text{ r.p.m.}, E_{b2} = ?$   
 Using  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \quad (\because \Phi_1 = \Phi_2)$   
 we get  $E_{b2} = 170 \times (630/595) = 180 \text{ V}$   
 Let  $R_2$  be the new value of armature circuit resistance for raising the speed from 595 r.p.m. to 630 r.p.m.

$\therefore 180 = 200 - 50 R_2 \quad \therefore R = 0.4 \Omega$   
 Hence, armature circuit resistance should be reduced by  $0.6 - 0.4 = 0.2 \Omega$ .

(i) We have seen above that

$I_{a1} = 50 \text{ A}, E_{b1} = 170 \text{ V}, N_1 = 595 \text{ r.p.m.}$   
 If  $I_{a2} = 15 \text{ A}, E_{b2} = 200 - (15 \times 0.6) = 191 \text{ V}$   
 $\therefore \frac{N_2}{595} = \frac{191}{170} \quad \therefore N_2 = 668.5 \text{ r.p.m.}$

(ii) When armature divertor is used (Fig. 30.8).

Let  $R$  be the new value of series resistance

$\therefore E_{b3} = 200 - IR - (50 \times 0.02) = 199 - IR$   
 Since speed is 595 r.p.m.,  $E_{b3}$  must be equal to 170 V  
 $\therefore 170 = 199 - IR \quad \therefore IR = 29 \text{ V}; \text{ P.D. across divertor} = 200 - 29 = 171 \text{ V}$   
 Current through divertor  $I_d = 171/5 = 34.2 \text{ A} \quad \therefore I = 50 + 34.2 = 84.2 \text{ A}$   
 As  $IR = 29 \text{ V} \quad \therefore R = 29/84.2 = 0.344 \text{ W}$   
 When  $I_a = 15 \text{ A}$ , then  $I_d = (I - 15) \text{ A}$   
 P.D. across divertor =  $5(I - 15) = 200 - 0.344 I \quad \therefore I = 51.46 \text{ A}$   
 $E_{b4} = 200 - 0.344 I - (15 \times 0.02)$   
 $= 200 - (0.344 \times 51.46) - 0.3 = 182 \text{ V}$   
 $\therefore \frac{N_4}{N_1} = \frac{E_{b4}}{E_{b1}} \quad \text{or} \quad \frac{N_4}{595} = \frac{182}{170} \quad \therefore N_4 = 637 \text{ r.p.m.}$

The effect of armature divertor is obvious. The speed without divertor is 668.5 r.p.m. and with armature divertor, it is 637 r.p.m.

(iii) Voltage Control Method

(a) Multiple Voltage Control

In this method, the shunt field of the motor is connected permanently to a fixed exciting voltage, but the armature is supplied with different voltages by connecting it across one of the several different voltages by means of suitable switchgear. The armature speed will be approximately proportional to these different voltages. The intermediate speeds can be obtained by adjusting the shunt field regulator. The method is not much used, however.

(b) Ward-Leonard System

This system is used where an unusually wide (upto 10 : 1) and very sensitive speed control is required as for colliery winders, electric excavators, elevators and the main drives in steel mills and blooming and paper mills. The arrangement is illustrated in Fig. 30.9.

$M_1$  is the main motor whose speed control is required. The field of this motor is permanently connected across the d.c. supply lines. By applying a variable voltage across its armature, any desired

speed can be obtained. This variable voltage is supplied by a motor-generator set which consists of either a d.c. or an a.c. motor  $M_2$  directly coupled to generator  $G$ .

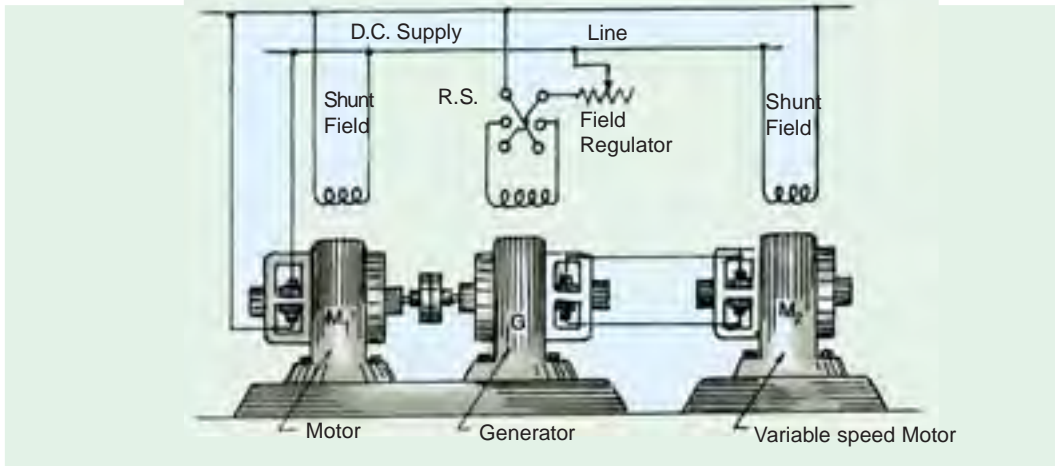

Fig. 30.9

The motor  $M_2$  runs at an approximately constant speed. The output voltage of  $G$  is directly fed to the main motor  $M_1$ . The voltage of the generator can be varied from zero up to its maximum value by means of its field regulator. By reversing the direction of the field current of  $G$  by means of the reversing switch  $RS$ , generated voltage can be reversed and hence the direction of rotation of  $M_1$ . It should be remembered that motor generator set always runs in the same direction.

Despite the fact that capital outlay involved in this system is high because (i) a large output machine must be used for the motor generator set and (ii) that two extra machines are employed, still it is used extensively for elevators, hoist control and for main drive in steel mills where motor of ratings 750 kW to 3750 kW are required. The reason for this is that the almost unlimited speed control in either direction of rotation can be achieved entirely by field control of the generator and the resultant economies in steel production outweigh the extra expenditure on the motor generator set.

A modification of the Ward-Leonard system is known as Ward-Leonard-Ilgner system which uses a smaller motor-generator set with the addition of a flywheel whose function is to reduce fluctuations in the power demand from the supply circuit. When main motor  $M_1$  becomes suddenly overloaded, the driving motor  $M_2$  of the motor generator set slows down, thus allowing the inertia of the flywheel to supply a part of the overload. However, when the load is suddenly thrown off the main motor  $M_1$ , then  $M_2$  speeds up, thereby again storing energy in the flywheel.

When the Ilgner system is driven by means of an a.c. motor (whether induction or synchronous) another refinement in the form of a 'slip regulator' can be usefully employed, thus giving an additional control.

The chief disadvantage of this system is its low overall efficiency especially at light loads. But as said earlier, it has the outstanding merit of giving wide speed control from maximum in one direction through zero to the maximum in the opposite direction and of giving a smooth acceleration.

**Example 30.30.** The O.C.C. of the generator of a Ward-Leonard set is

Field amps :	1.4	2.2	3	4	5	6	7	8
Armature volts :	212	320	397	472	522	560	586	609

The generator is connected to a shunt motor, the field of which is separately-excited at 550 V. If the speed of motor is 300 r.p.m. at 550 V, when giving 485 kW at 95.5% efficiency, determine the excitation of the generator to give a speed of 180 r.p.m. at the same torque. Resistance of the motor

armature circuit = 0.01 Ω, resistance of the motor field = 60 Ω, resistance of generator armature circuit = 0.01 Ω. Ignore the effect of armature reaction and variation of the core factor and the windage losses of the motor.

**Solution.** Motor input =  $485 \times 10^3 / 0.955 = 509,300 \text{ W}$

Motor to motor field =  $550 / 60 = 55 / 6 \text{ A}$

Input to motor field =  $550 \times 55 / 6 = 5,040 \text{ W}$

∴ Motor armature input =  $509,300 - 5,040 = 504,260 \text{ W}$

∴ Armature current =  $504,260 / 550 = 917 \text{ A}$

Back e.m.f.  $E_{b1}$  at 300 r.p.m. =  $550 - (917 \times 0.01) = 540.83 \text{ V}$

Back e.m.f.  $E_{b2}$  at 180 r.p.m. =  $540.83 \times 180 / 300 = 324.5 \text{ V}$

Since torque is the same, the armature current of the main motor is also the same i.e. 917 A because its excitation is independent of its speed.

∴  $V = 324.5 + (917 \times 0.01) = 333.67 \text{ V}$

Generated e.m.f. =  $V + I_a R_a$  ...for generator

$333.67 + (917 \times 0.011) = 343.77 \text{ V}$

If O.C.C. is plotted from the above given data, then it would be found that the excitation required to give 343.77 V is 2.42 A.

∴ Generator exciting current = **2.42 A**

### 30.3. Speed Control of Series Motors

#### 1. Flux Control Method

Variations in the flux of a series motor can be brought about in any one of the following ways :

##### (a) Field Divertors

The series winding are shunted by a variable resistance known as field diverter (Fig. 30.10). Any desired amount of current can be passed through the diverter by adjusting its resistance. Hence the flux can be decreased and consequently, the speed of the motor increased.

Fig. 30.10

##### (b) Armature Divertor

A diverter across the armature can be used for giving speeds lower than the normal speed (Fig. 30.11). For a **given constant load torque**, if  $I_a$  is reduced due to armature diverter, the  $\Phi$  must increase.

(∵  $T_a \propto \Phi I_a$ ). This results in an increase in current taken from the supply (which increases the flux and a fall in speed ( $N \propto I/\Phi$ )). The variation in speed can be controlled by varying the diverter resistance.

Fig. 30.11

Fig. 30.12

**(c) Trapped Field Control Field**

This method is often used in electric traction and is shown in Fig. 30.12.

The number of series filed turns in the circuit can be changed at will as shown. With full field, the motor runs at its minimum speed which can be raised in steps by cutting out some of the series turns.

**(d) Paralleling Field coils**

In this method, used for fan motors, several speeds can be obtained by regrouping the field coils as shown in Fig. 30.13. It is seen that for a 4-pole motor, three speeds can be obtained easily. (Ex.30.35)

Fig. 30.13

**2. Variable Resistance in Series with Motor**

By increasing the resistance in series with the armature (Fig. 30.14) the voltage applied across the armature terminals can be decreased.

With reduced voltage across the armature, the speed is reduced. However, it will be noted that since full motor current passes through this resistance, there is a considerable loss of power in it.

Fig. 30.14

**Example 30.31.** A d.c. series motor drives a load the torque of which varies as the square of the speed. The motor takes a current of 15 A when the speed is 600 r.p.m. Calculate the speed and the current when the motor field winding is shunted by a diverter of the same resistance as that of the field winding. Mention the assumptions made, if any. (Elect. Machines, AMIE Sec B, 1993)

**Solution.**

$$T_{a1} \propto N_1^2, T_{a2} \propto N_2^2 \quad \therefore T_{a2}/T_{a1} = N_2^2/N_1^2$$

Also,

$$T_{a1} \propto \Phi_1 I_{a1} \propto I_{a1}^2, T_{a2} \propto \Phi_2 I_{a2} \propto (I_{a2}/2) I_{a2} \propto I_{a2}^2/2$$

It is so because in the second case, field current is half the armature current.

$$\therefore \frac{N_2^2}{N_1^2} = \frac{I_{a2}^2/2}{I_{a1}^2} \quad \text{or} \quad \frac{N_2}{N_1} = \frac{I_{a2}}{\sqrt{2} I_{a1}} \quad \dots (i)$$

Now, 
$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$$

If we neglect the armature and series winding drops as well as brush drop, then  $E_{b1} = E_{b2} = V$

$$\frac{N_2}{N_1} = \frac{\Phi_1}{\Phi_2} = \frac{\tau_1}{\tau_2} = \frac{2\tau_1}{\tau_2} \quad \dots(ii)$$

From (i) and (ii), 
$$\frac{I_{a2}}{\sqrt{2} I_{a1}} = \frac{2 I_{a1}}{I_{a2}} \quad \text{or} \quad I_{a2}^2 = 2\sqrt{2} I_{a1}^2 = 2\sqrt{2} \times 15^2 \quad \text{or} \quad I_{a2} = 25.2 \text{ A}$$

From (ii), we get, 
$$N_2 = 600 \times 2 \times 15/25.2 = 714 \text{ r.p.m.}$$

**Example 30.32.** A 2-pole series motor runs at 707 r.p.m. when taking 100 A at 85 V and with the field coils in series. The resistance of each field coil is 0.03 Ω and that of the armature 0.04 Ω. If the field coils are connected in parallel and load torque remains constant, find (a) speed (b) the additional resistance to be inserted in series with the motor to restore the speed to 707 r.p.m.

**Solution.** Total armature circuit resistance = 0.04 + (2 × 0.03) = 0.1 Ω

$$I_{a1} = 100 \text{ A} ; E_{b1} = 85 - (100 \times 0.1) = 75 \text{ V}$$

When series field windings are placed in parallel, the current through each is half the armature current.

If  $I_{a2}$  = new armature current ; then  $\Phi_2 \propto I_{a2}/2$ .

As torque is the same in the two cases,

$$\therefore \Phi_1 I_{a1} = \Phi_2 I_{a2} \quad \text{or} \quad I_{a1}^2 = \frac{I_{a2}}{2} \times I_{a2} = \frac{I_{a2}^2}{2}$$

$$\therefore 100^2 = \frac{I_{a2}^2}{2} \quad \therefore I_{a2} = 100 \sqrt{2} = 141.4 \text{ A}$$

In this case, series field resistance = 0.03/2 = 0.015 Ω

$$\therefore E_{b2} = 85 - 141.4 (0.04 + 0.015) = 77.22 \text{ V}$$

$$\frac{N_2}{707} = \frac{77.22}{75} \times \frac{100}{141.4/2} \quad (\because \Phi_2 \propto I_{a2}/2)$$

(a)  $\therefore N_2 = 707 \times \frac{77.22}{75} \times \frac{200}{141.4} = 1029 \text{ r.p.m.}$

(b) Let the total resistance of series circuit be  $R_t$ .

Now,  $E_{b1} = 77.22 \text{ V}, N_1 = 1029 \text{ r.p.m.} ; E_{b2} = 85 - 141.4 R_t, N_2 = 707 \text{ r.p.m.}$

$$\frac{707}{1029} = \frac{85 - 141.4 R_t}{77.22} \quad \therefore R_t = 0.226 \Omega$$

$\therefore$  Additional resistance = 0.226 - 0.04 - 0.015 = 0.171 Ω

**Example 30.33.** A 240 V series motor takes 40 amperes when giving its rated output at 1500 r.p.m. Its resistance is 0.3 ohm. Find what resistance must be added to obtain rated torque (i) at starting (ii) at 1000 r.p.m. (Elect. Engg., Madras Univ. 1987)

**Solution.** Since torque remains the same in both cases, it is obvious that current drawn by the motor remains constant at 40 A. ( $\because T_a \propto I_a^2$ )

(i) If  $R$  is the series resistance added, then  $40 = 240/(R + 0.3) \quad \therefore R = 5.7 \Omega$

(ii) Current remaining constant,  $T_a \propto E_b/N$  – Art. 29.7

$$\frac{E_{b1}}{N_1} = \frac{E_{b2}}{N_2}$$

Now,  $E_{b1} = 240 - 40 \times 0.3 = 228 \text{ V} ; N_1 = 1500 \text{ r.p.m.}$

$$E_{b2} = 240 - 40 (R + 0.3) \text{ V} ; N_2 = 1000 \text{ r.p.m.}$$

$$\therefore \frac{228}{1500} = \frac{240 - 40(R + 0.3)}{1000}; R = 1.9 \Omega$$

**Example 30.34.** A 4-pole, series-wound fan motor runs normally at 600 r.p.m. on a 250 V d.c. supply taking 20 A. The field coils are connected in series. Estimate the speed and current taken by the motor if the coils are reconnected in two parallel groups of two in series. The load torque increases as the square of the speed. Assume that the flux is directly proportional to the current and ignore losses. **(Elect. Machines, AMIE, Sec B. 1990)**

**Solution.** When coils are connected in two parallel groups, current through each becomes  $I_{a2}/2$  where  $I_{a2}$  is the new armature current.

Hence,  $\Phi_2 \propto I_{a2}/2$   
 Now  $T_a \propto \Phi I_a$   
 $\propto N^2$  - given

$$\therefore \Phi_1 I_{a1} \propto N_1^2 \text{ and } \Phi_2 I_{a2} \propto N_2^2 \quad \therefore \left(\frac{N_2}{N_1}\right)^2 = \frac{\Phi_2 I_{a2}}{\Phi_1 I_{a1}} \quad \dots (i)$$

Since losses are negligible, field coil resistance as well as armature resistance are negligible. It means that armature and series field voltage drops are negligible. Hence, back e.m.f. in each case equals the supply voltage.

$$\therefore \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} \text{ becomes } \frac{N_2}{N_1} = \frac{\Phi_1}{\Phi_2} \quad \dots (ii)$$

Putting this value in (i) above, we get

$$\left(\frac{\Phi_1}{\Phi_2}\right)^2 = \frac{\Phi_2 I_{a2}}{\Phi_1 I_{a1}} \text{ or } \frac{I_{a2}}{I_{a1}} = \left(\frac{\Phi_1}{\Phi_2}\right)^3$$

Now,  $\Phi_1 \propto 20$  and  $\Phi_2 \propto I_{a2}/2$   $\therefore \frac{I_{a2}}{20} = \left(\frac{20}{I_{a2}/2}\right)^3$  or  $I_{a2} = 20 \times 2^{3/4} = 33.64 \text{ A}$

From (ii) above, we get  $\frac{N_2}{N_1} = \frac{\Phi_1}{\Phi_2} = \frac{I_{a1}}{I_{a2}/2} = \frac{2 I_{a1}}{I_{a2}}$ ;  $N_2 = 600 \times 2 \times 20/33.64 = 714 \text{ r.p.m.}$

**Example 30.35.** A d.c. series motor having a resistance of 1 Ω drives a fan for which the torque varies as the square of the speed. At 220 V, the set runs at 350 r.p.m. and takes 25 A. The speed is to be raised to 500 r.p.m. by increasing the voltage. Determine the necessary voltage and the corresponding current assuming the field to be unsaturated. **(Electrical Engg., Banaras Hindu Univ. 1998)**

**Solution.** Since  $\Phi \propto I_a$ , hence  $T_a \propto \Phi I_a \propto I_a^2$ . Also  $T_a \propto N^2$  ... (given)

$$\therefore I_a^2 \propto N^2 \text{ or } I_a \propto N \text{ or } I_{a1} \propto N_1 \text{ and } I_{a2} \propto N_2$$

$$\therefore \frac{I_{a2}}{I_{a1}} = \frac{N_2}{N_1} = \frac{500}{350}; I_{a2} = 25 \times \frac{500}{350} = \frac{250}{7} \text{ A}$$

$$E_{b1} = 220 - 25 \times 1 = 195 \text{ V}; E_{b1} = V - (250/7) \times 1, \frac{\Phi_1}{\Phi_2} = \frac{25}{250/7} = \frac{7}{10}$$

Now  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}; \frac{500}{350} = \frac{V - (250/7)}{195} \times \frac{7}{10}; V = 433.7 \text{ V}$

**Example 30.36.** A d.c. series motor runs at 1000 r.p.m. when taking 20 A at 200 V. Armature resistance is 0.5 Ω. Series field resistance is 0.2 Ω. Find the speed for a total current of 20 A when a diverter of 0.2 Ω resistance is used across the series field. Flux for a field current of 10 A is 70 per cent of that for 20 A.

**Solution.**  $E_{b1} = 200 - (0.5 + 0.2) \times 20 = 186 \text{ V}$  ;  $N_1 = 1000 \text{ r.p.m.}$

Since diverter resistance equals series field resistance, the motor current of 20 A is divided equally between the two. Hence, a current of 10 A flows through series field and produces flux which is 70% of that corresponding to 20 A. In other words,  $\Phi_2 = 0.7$  or  $\Phi_1/\Phi_2 = 1/0.7$

Moreover, their combined resistance =  $0.2/2 = 0.1 \Omega$

Total motor resistance becomes =  $0.5 + 0.1 = 0.6 \Omega$

$$\therefore E_{b2} = 200 - 0.6 \times 20 = 188 \text{ V} ; N_2 = ?$$

$$\therefore \frac{N_2}{1000} = \frac{188}{186} \times \frac{1}{0.7} ; N_2 = \mathbf{1444 \text{ r.p.m.}}$$

**Example 30.37.** A 200 V, d.c. series motor takes 40 A when running at 700 r.p.m. Calculate the speed at which the motor will run and the current taken from the supply if the field is shunted by a resistance equal to the field resistance and the load torque is increased by 50%.

Armature resistance =  $0.15 \Omega$ , field resistance =  $0.1 \Omega$

It may be assumed that flux per pole is proportional to the field.

**Solution.** In a series motor, prior to magnetic saturation

$$T \propto \Phi I_a \propto I_a^2 \quad \therefore T_1 \propto I_{a1}^2 \propto 40^2 \quad \dots(i)$$

If  $I_{a2}$  is the armature current (or motor current) in the second case when diverter is used, then only  $I_{a2}/2$  passes through the series field winding.

$$\therefore \Phi_2 \propto I_{a2}/2 \text{ and } T_2 \propto \Phi_2 I_{a2} \propto (I_{a2}/2) \times I_{a2} \propto I_{a2}^2/2 \quad \dots(ii)$$

From (i) and (ii), we get  $\frac{T_2}{T_1} = \frac{I_{a2}^2}{2 \times 40^2}$

Also  $T_2/T_1 = 1.5 \quad \therefore 1.5 = I_{a2}^2/2 \times 40^2$

$$\therefore I_{a2} = \sqrt{1.5 \times 2 \times 40^2} = 69.3 \text{ A} ;$$

Now  $E_{b1} = 220 - (40 \times 0.25) = 210 \text{ V}$

$$E_{b2} = 220 - (69.3 \times 0.2^*) = 206.14 \text{ V} ; N_1 = 700 \text{ r.p.m.} ; N_2 = ?$$

$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} \quad \therefore \frac{N_2}{700} = \frac{206.14}{210} \times \frac{40}{69.3/2} \quad \therefore N_2 = \mathbf{794 \text{ r.p.m.}}$$

**Example 30.38.** A 4-pole, 250 V d.c. series motor takes 20 A and runs at 900 r.p.m. Each field coil has resistance of 0.025 ohm and the resistance of the armature is 0.1 ohm. At what speed will the motor run developing the same torque if :

(i) a diverter of 0.2 ohm is connected in parallel with the series field

(ii) rearranging the field coils in two series and parallel groups

Assume unsaturated magnetic operation.

(Electric Drives and their Control, Nagpur Univ. 1993)

**Solution.** The motor with its field coils all connected in series is shown in Fig. 30.15 (a). Here,  $N_1 = 900 \text{ r.p.m.}$ ,  $E_{b1} = 250 - 20 \times (0.1 + 4 \times 0.025) = 246 \text{ V}$ .

In Fig. 30.15 (b), a diverter of resistance  $0.2 \Omega$  has been connected in parallel with the series field coils. Let  $I_{a2}$  be the current drawn by the motor under this condition. As per current-divider rule, part of the current passing through the series fields is  $I_{a2} \times 0.2 / (0.1 + 0.2) = 2 I_{a2} / 3$ . Obviously,  $\Phi_2 \propto 2 I_{a2} / 3$ .

\* The combined resistance of series field winding and the diverter is  $0.1/2 = 0.05 \Omega$ . Hence, the total resistance =  $0.15 + 0.05 = 0.2 \Omega$ , in example 30.37.

Now,  $T_1 \propto \Phi_1 I_{a1} \propto I_{a1}^2$ ;  $T_2 \propto \Phi_2 I_{a2} \propto (2 I_{a2}/3) I_{a2} \propto 2 I_{a2}^2/3$   
 Since  $T_1 = T_2$ ;  $\therefore I_{a1}^2 = 2 I_{a2}^2/3$  or  $20^2 = 2 I_{a2}^2/3$ ;  $\therefore I_{a2} = 24.5$  A.  
 Combined resistance of the field and diverter  $= 0.2 \times 0.1/0.3 = 0.667 \Omega$ ; Arm. circuit resistance  $= 0.1 + 0.0667 = 0.1667 \Omega$ ;  $E_{b2} = 250 - 24.5 \times 0.1667 = 250 - 4.1 = 245.9$  V  
 $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$ ;  $\frac{N_2}{900} = \frac{245.9}{246} \times \frac{20}{(2/3) 24.5}$ ;  $N_2 = 1102$  r.p.m.  $\dots(\because \Phi_2 \propto 2 I_{a2}/3)$

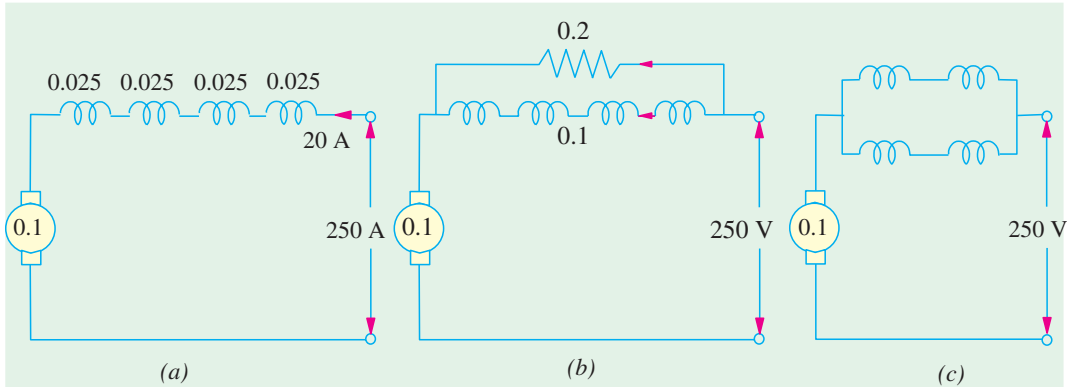

Fig. 30.15

(ii) In Fig. 30.15 (c), the series field coils have been arranged in two parallel groups. If the motor current is  $I_{a2}$ , then it is divided equally between the two parallel paths. Hence,  $\Phi_2 \propto I_{a2}/2$ .

Since torque remains the same,

$$T_1 \propto \Phi_1 I_{a1} \propto I_{a1}^2 \propto 20^2$$

$$T_2 \propto \Phi_2 I_{a2} \propto (I_{a2}/2) I_{a2} \propto I_{a2}^2/2$$

Since  $T_1 = T_2$ ;  $\therefore 20^2 = I_{a2}^2/2$ ;  $I_{a2} = 28.28$  A

Combined resistance of the two parallel paths  $= 0.05/2 = 0.025 \Omega$

Total arm. circuit resistance  $= 0.1 + 0.025 = 0.125 \Omega$

$\therefore E_{b2} = 250 - 28.28 \times 0.125 = 246.5$  V

$$\frac{N_2}{900} = \frac{246.5}{246} \times \frac{20}{28.28/2}$$

$$N_2 = 1275 \text{ r.p.m.}$$

**Example 30.39.** A 4-pole, 230 V series motor runs at 1000 r.p.m., when the load current is 12 A. The series field resistance is 0.8  $\Omega$  and the armature resistance is 1.0  $\Omega$ . The series field coils are now regrouped from all in series to two in series with two parallel paths. The line current is now 20 A. If the corresponding weakening of field is 15%, calculate the speed of the motor.

(Electrotechnology-I, Guwahati Univ. 1987)

Fig. 30.16

**Solution.**  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$ ,  $E_{b1} = 230 - 12 \times 1.8 = 208.4$  V, as in Fig. 30.16(a)

For circuit in Fig. 30.16 (b),

$$E_{b2} = 230 - 20(1 + 0.4/2) = 206 \text{ V ;}$$

$$\Phi_2 = 0.85 \Phi_1 \text{ or } \Phi_1/\Phi_2 = 1/0.85$$

$$\therefore \frac{N_2}{1000} = \frac{206}{208.4} \times \frac{1}{0.85} \quad \therefore N_2 = \mathbf{1163 \text{ r.p.m.}}$$

**Example 30.40.** A 200 V, d.c. series motor runs at 500 r.p.m. when taking a line current of 25 A. The resistance of the armature is 0.2 Ω and that of the series field 0.6 Ω. At what speed will it run when developing the same torque when armature diverter of 10 Ω is used ? Assume a straight line magnetisation curve. (D.C. Machines, Jadavpur Univ. 1988)

**Solution.** Resistance of motor = 0.2 + 0.6 = 0.8 Ω

$$\therefore E_{b1} = 200 - (25 \times 0.8) = 180 \text{ V}$$

Let the motor input current be  $I_2$ , when armature diverter is used, as shown in Fig. 30.17.

$$\text{Series field voltage drop} = 0.6 I_2$$

$$\therefore \text{P.D. at brushes} = 200 - 0.6 I_2$$

$$\therefore \text{Arm. diverter current} = \left( \frac{200 - 0.6 I_2}{10} \right) \text{ A}$$

$$\therefore \text{Armature current} = I_2 \left( \frac{200 - 0.6 I_2}{10} \right)$$

$$\therefore I_{a2} = \frac{10.6 I_2 - 200}{10}$$

As torque in both cases is the same,  $\therefore \Phi_1 I_{a1} = \Phi_2 I_{a2}$

$$\therefore 25 \times 25 = I_2 \left( \frac{10.6 I_2 - 200}{10} \right) \text{ or } 6,250 = 10.6 I_2^2 - 200 I_2$$

$$\text{or } 10.6 I_2^2 - 200 I_2 - 6250 = 0 \text{ or } I_2 = 35.6 \text{ A}$$

$$\text{P.D. at brushes in this case} = 200 - (35.6 \times 0.6) = 178.6 \text{ V}$$

$$\therefore I_{a2} = \frac{10.6 \times 35.6 - 200}{10} = 17.74 \text{ A;}$$

$$E_{b2} = 178.6 - (17.74 \times 0.2) = 175 \text{ V}$$

$$\text{Now } \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2} \text{ or } \frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{I_1}{I_2} \quad (\because \Phi \propto I)$$

$$\therefore \frac{N_2}{500} = \frac{175}{180} \times \frac{25}{35.6} \quad \therefore N_2 = \mathbf{314 \text{ r.p.m.}}$$

Fig. 30.17

**Example 30.41.** A series motor is running on a 440 V circuit with a regulating resistance of  $R$  Ω for speed adjustment. The armature and field coils have a total resistance of 0.3 Ω. On a certain load with  $R = \text{zero}$ , the current is 20 A and speed is 1200 r.p.m. With another load and  $R = 3$  Ω, the current is 15 A. Find the new speed and also the ratio of the two values of the power outputs of the motor. Assume the field strength at 15 A to be 80% of that at 20 A.

**Solution.**  $I_{a1} = 20 \text{ A}, R_a = 0.3 \text{ } \Omega$  ;  $E_{b1} = 440 - (20 \times 0.3) = 434 \text{ V}$

$$I_{a2} = 15 \text{ A}, R_a = 3 + 0.3 = 3.3 \text{ } \Omega \therefore E_{b2} = 440 - (3.3 \times 15) = 390.5 \text{ V}$$

$$\Phi_2 = 0.8 \Phi_1, N_1 = 1200 \text{ r.p.m.}$$

Using  $\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \times \frac{\Phi_1}{\Phi_2}$ , we get  $N_2 = 1200 \times \frac{390.5}{434} \times \frac{1}{0.8} = 1350 \text{ r.p.m.}$

Now, in a series motor,

$$T \propto \Phi I_a \text{ and power } P \propto T \times N \text{ or } P \propto \Phi N I_a$$

$$\therefore P_1 \propto \Phi_1 \times 1200 \times 20 \text{ and } P_2 \propto 0.8 \Phi_1 \times 1350 \times 15$$

$$\therefore \frac{P_1}{P_2} = \frac{1200 \times 20 \Phi_1}{1350 \times 15 \times 0.8 \Phi_1} = 1.48$$

Hence, power in the first case is 1.48 times the power in the second case.

**Example 30.42.** A d.c. series with an unsaturated field and negligible resistance, when running at a certain speed on a given load takes 50 A at 460 V. If the load-torque varies as the cube of the speed, calculate the resistance required to reduce the speed by 25%.

(Nagpur, Univ. November 1999, Madras Univ. 1987)

**Solution.** Let the speed be  $\omega$  radians/sec and the torque,  $T_{em}$  Nw-m developed by the motor. Hence power handled =  $T \cdot \omega$  watts

Let load torque be  $T_L$ ,  $T_L \propto \omega^3$   
 $T_L = T_{em}$ ,  $T_{em} \propto (50)^2$

Hence Load power =  $T_L \omega$

Since no losses have to be taken into account,  $50^2 \propto \omega^3$

Armature power,  $460 \times 50 \propto \omega^4$

Based on back e.m.f. relationship,  $E_b \propto \omega I_a$

$$460 \propto \omega \times 50$$

To reduce the speed by 25%, operating speed =  $0.75 \omega$  rad/sec

Let the new current be  $I$ .

From Load side torque  $\propto (0.75 \omega)^3$

From electro-mech side,  $T \propto I^2$   
 $I^2 \propto (0.75 \omega)^3$

Comparing similar relationship in previous case,

$$\frac{I^2}{50^2} = \frac{(0.75 \omega)^3}{\omega^3} = 0.75^3$$

$$I^2 = 50^2 \times 0.422 = 1055$$

$$I = 32.48 \text{ amp}$$

$$E_{b2} \propto I \times \text{speed}$$

$$\propto I \times 0.75 \omega$$

$$\propto 32.48 \times 0.75 \omega$$

$$\frac{E_{b2}}{460} = \frac{32.48 \times 0.75}{50}$$

$$E_{b2} = 224 \text{ volts}$$

If  $R$  is the resistance externally connected in series with the motor,

$$E_{b2} = 460 - 32.48 \times R = 224$$

$$\therefore R = 7.266 \text{ ohms}$$

$$\text{Previous armature power} = 460 \times 50 \times 10^{-3} = 23 \text{ kW}$$

New armature power should be

$$23 \times (0.75)^4 = 7.28 \text{ kW}$$

With  $E_b$  as 224 V and current as 32.48 amp

$$\begin{aligned} \text{Armature power} &= 224 \times 32.48 \text{ watts} \\ &= 7.27 \text{ kW} \end{aligned}$$

Thus, the final answer is checked by this step, since the results agree.

**Example 30.43.** A d.c. series motor drives a load, the torque of which varies as the square of speed. The motor takes a current of 15 A when the speed is 600 r.p.m. Calculate the speed and current when the motor-field-winding is shunted by a diverter of equal resistance as that of the field winding. Neglect all motor losses and assume the magnetic circuit as unsaturated.

(Bharathithasan Univ. April 1997)

**Solution.** Let the equations governing the characteristics of series motor be expressed as follows, with no losses and with magnetic circuit unsaturated.

Torque developed by motor = Load torque

$$k_m \times i_{se} \times I_a = k_L \times (600)^2$$

where  $k_m, k_L$  are constants

$I_{se}$  = series field current

$I_a$  = Armature current

In the first case

$$i_{se} = I_a$$

With diverter,

$$i_{se} = i_d = 0.5 I_a,$$

Since, the resistances of diverter and series field are equal.

$$\text{In the first case, } k_m \times 15 \times 15 = k_L \times (600)^2 \quad \dots(a)$$

Let the supply voltage be  $V_L$  volts.

Since Losses are to be neglected, armature receives a power of  $(V_L \times 15)$  watts.

Case (ii) Let the new speed =  $N_2$  r.p.m. and the new armature current =  $I_{a2}$  amp

So that new series-field current =  $0.5 I_{a2}$

Torque developed by motor = Load torque

$$k_m \times (0.5 I_{a2}) \times I_{a2} = k_L \times (N_2)^2 \quad \dots(b)$$

From equations (a) and (b) above,

$$\frac{0.5 I_{a2}^2}{225} = \frac{N_2^2}{600^2}$$

$$\text{or } \left( \frac{N_2}{I_{a2}} \right)^2 = \frac{600^2}{450} = 800 \quad \dots(c)$$

$$\text{or } N_2/I_{a2} = 28.28 \quad \dots(d)$$

Now armature receives a power of  $I_{a2} V_L$  watts. Mechanical outputs in the two cases have to be related with these electrical-power-terms.

$$k_L = (600)^2 \times 2600/60 = 15 V_L \quad \dots(e)$$

$$k_L = N^2 \times 2 N/60 = I_{a2} V_L \quad \dots(f)$$

From these two equations,

$$N^3/600^3 = I_{a2}/15 \quad \dots(g)$$

$$\text{From (c) and (g), } N_2 I_{a2} = 18,000 \quad \dots(h)$$

Fig. 30.18 (Diverter for speed control)

From (d) and (h),  $N_2 = 713.5$  r.p.m.

And  $I_{a2} = 25.23$  amp

**Additional Correlation :** Since the load-torque is proportional to the square of the speed, the mechanical output power is proportional to the cube of the speed. Since losses are ignored, electrical power (input) must satisfy this proportion.

$$(15 V_L) / (25.23 V_L) = (600/713.5)^3$$

$$\text{L.H.S.} = 0.5945, \text{R.H.S.} = 0.5947$$

Hence, correlated and checked.

### 30.4. Merits and Demerits of Rheostatic Control Method

1. Speed changes with every change in load, because speed variations depend not only on controlling resistance but on load current also. This double dependence makes it impossible to keep the speed sensibly constant on rapidly changing loads.
2. A large amount of power is wasted in the controller resistance. Loss of power is directly proportional to the reduction in speed. Hence, efficiency is decreased.
3. Maximum power developed is diminished in the same ratio as speed.
4. It needs expensive arrangement for dissipation of heat produced in the controller resistance.
5. It gives speeds *below* the normal, not above it because armature voltage can be decreased (not increased) by the controller resistance.

This method is, therefore, employed when low speeds are required for a short period only and that too occasionally as in printing machines and for cranes and hoists where motor is continually started and stopped.

#### Advantages of Field Control Method

This method is economical, more efficient and convenient though it can give speeds *above* (not below) the normal speed. The only limitation of this method is that commutation becomes unsatisfactory, because the effect of armature reaction is greater on a weaker field.

It should, however, be noted that by combining the two methods, speeds above and below the normal may be obtained.

### 30.5. Series-parallel Control

In this system of speed control, which is widely used in electric traction, two or more similar mechanically-coupled series motors are employed. At low speeds, the motors are joined in series Fig. 30.19 (a) and for high speeds, are joined in parallel Fig. 30.19 (b).

When in series, the two motors have the same current passing through them, although the voltage across each motor is  $V/2$  i.e., half the supply voltage. When joined in parallel, voltage across each machines is  $V$ , though current drawn by each motor is  $I/2$ .

#### When in Parallel

Now speed  $\propto E_b / \phi \propto E_b / \text{current}$   
(being series motors)

Fig. 30.19 (a)

Fig. 30.19 (b)

Since  $E_b$  is approximately equal to the applied voltage  $V$  :

$$\therefore \text{speed} \propto \frac{V}{I/2} \propto \frac{2V}{I}$$

Also,  $\text{torque} \propto \Phi I \propto I^2$  ( $\because \Phi \propto I$ ) ...**(i)**

$\therefore T \propto (I/2)^2 \propto I^2/4$  ...**(ii)**

**When in Series**

Here  $\text{speed} \propto \frac{E_b}{\Phi} \propto \frac{V/2}{I} \propto \frac{V}{2I}$  ...**(iii)**

*This speed is one-fourth of the speed of the motors when in parallel.*

Similarly  $T \propto \Phi I \propto I^2$

*The torque is four times that produced by motors when in parallel.*

This system of speed control is usually combined with the variable resistance method of control described in Art. 30.3 (2).

The two motors are started up in series with each other and with variable resistance which is cut out in sections to increase the speed. When all the variable series resistance is cut out, the motors are connected in parallel and at the same time, the series resistance is reinserted. The resistance is again reduced gradually till full speed is attained by the motors. The switching sequence is shown in Fig.30.20. As the variable series controller resistance is not continuously rated, it has to be cut out of the circuit fairly quickly although in the four running positions A, B, C and D, it may be left in circuit for any length of time.

Fig. 30.20

**Example 30.44.** Two series motors run at a speed of 500 r.p.m. and 550 r.p.m. respectively when taking 50 A at 500 V. The terminal resistance of each motor is 0.5 Ω. Calculate the speed of the combination when connected in series and coupled mechanically. The combination is taking 50 A on 500 V supply. **(Electrical Machinery-I, Mysore Univ. 1985)**

**Solution. First Motor**

$$E_{b1} = 500 - (50 \times 0.5) = 475 \text{ V} ; I = 50 \text{ A}$$

Now,  $N_1 \propto E_{b1}/\Phi_1$  or  $E_{b1} \propto N_1 \Phi_1$  or  $E_{b1} = k N_1 \Phi_1$

$\therefore 475 = k \times 500 \times \Phi_1 \therefore k \Phi_1 = 475/500$

**Second Motor**  $E_{b2} = 500 - (50 \times 0.5) = 475 \text{ V}$ . Similarly,  $k \Phi_2 = 475/550$

**When both motors are in series**

$$E_b' = 500 - (50 \times 2 \times 0.5) = 450 \text{ V}$$

Now,  $E_b' = E_{b1} + E_{b2} = k \Phi_1 N + k \Phi_2 N$   
 where  $N$  is the common speed when joined in series.

$$\therefore 450 = \frac{475}{500} N + \frac{475}{550} N \quad \therefore N = 248 \text{ r.p.m.}$$

**Example 30.45.** Two similar 20 h.p. (14.92 kW), 250 V, 1000 r.p.m. series motors are connected in series with each other across a 250 V supply. The two motors drive the same shaft through a reduction gearing 5 : 1 and 4 : 1 respectively. If the total load torque on the shaft is 882 N-m, calculate (i) the current taken from the supply main (ii) the speed of the shaft and (iii) the voltage across each motor. Neglect all losses and assume the magnetic circuits to be unsaturated.

(Elect. Machines, Punjab Univ., 1991)

**Solution.** (i) Rated current of each motor =  $14,920/250 = 59.68 \text{ A}$

Back e.m.f.  $E_b = 250 \text{ V}$  (neglecting  $I_a R_a$  drop)

Now,  $E_b \propto N \Phi$  As  $\Phi \propto I \therefore E_b \propto NI$  or  $E_b = kNI$   
 $250 = k \times (1000/60) \times 59.68 \quad \therefore k = 0.25$

Let  $N_{sh}$  be the speed of the shaft.

Speed of the first motor  $N_1 = 5 N_{sh}$ ; Speed of the second motor  $N_2 = 4 N_{sh}$

Let  $I$  be the new current drawn by the series set, then

$$E_b' = E_{b1} + E_{b2} = kI \times 5 N_1 + kI \times N_2 = kI \times 5 N_{sh} + kI \times 4 N_{sh} \quad \dots(i)$$

$$250 = 9 \times kI N_{sh}$$

Now, torque  $T = 0.159 \frac{E_b I}{N} = 0.159 \times \frac{kI N_{sh} \times I}{N_{sh}} = 0.159 k I^2$

Shaft torque due to gears of 1st motor =  $5 \times 0.159 k I^2$

Shaft torque due to gears of 2nd motor =  $4 \times 0.159 k I^2$

$$\therefore 882 = k I^2 (5 \times 0.159 + 4 \times 0.159) = 1.431 k I^2$$

$$\therefore I^2 = 882/1.431 \times 0.25 = 2,449 \text{ A} \quad \therefore I = 49.5 \text{ A}$$

(ii) From equation (i), we get

$$250 = 9 \times 0.25 \times 49.5 \times N_{sh} \quad \therefore N_{sh} = 2.233 \text{ r.p.s.} = 134 \text{ r.p.m.}$$

(iii) Voltage across the armature of 1st motor is

$$E_{b1}' = 5 kI N_{sh} = 5 \times 0.25 \times 49.5 \times 2.233 = 139 \text{ V}$$

Voltage across the armature of 2nd motor

$$E_{b2}' = 4 kI N_{sh} = 4 \times 0.25 \times 49.5 \times 2.233 = 111 \text{ V}$$

Note that  $E_{b1}$  and  $E_{b2}$  are respectively equal to the applied voltage across each motor because  $I_a R_a$  drops are negligible.

### 30.6. Electric Braking

A motor and its load may be brought to rest quickly by using either (i) Friction Braking or (ii) Electric Braking. The commonly-used mechanical brake has one drawback : it is difficult to achieve a smooth stop because it depends on the condition of the braking surface as well as on the skill of the operator.

The excellent electric braking methods are available which eliminate the need of brake lining levers and other mechanical gadgets. Electric braking, both for shunt and series motors, is of the following three types: (i) rheostatic or dynamic braking

Strong electric brake for airwheels

- (ii) plugging *i.e.*, reversal of torque so that armature tends to rotate in the opposite direction and
- (iii) regenerative braking.

Obviously, friction brake is necessary for holding the motor even after it has been brought to rest.

### 30.7. Electric Braking of Shunt Motors

#### (a) Rheostatic or Dynamic Braking

In this method, the armature of the shunt motor is disconnected from the supply and is connected across a variable resistance  $R$  as shown in Fig. 30.21 (b). The field winding is, however, left connected across the supply undisturbed. The braking effect is controlled by varying the series resistance  $R$ . Obviously, this method makes use of generator action in a motor to bring it to rest.\* As seen from Fig. 30.21 (b), armature current is given by

$$I_a = \frac{E_b}{R + R_a} = \frac{\Phi Z N (P/A)}{R + R_a}$$

$$= \frac{k_1 \Phi N}{R + R_a}$$

Fig. 30.21

Braking torque is given by

$$T_B = \frac{1}{2\pi} \Phi Z I_a \left( \frac{P}{A} \right) \text{ N-m}$$

$$= \frac{1}{2\pi} \Phi Z \left( \frac{P}{A} \right) \cdot \frac{\Phi Z N (P/A)}{R + R_a} = \frac{1}{2\pi} \left( \frac{ZP}{A} \right)^2 \frac{\Phi^2 N}{R + R_a} = k_2 \Phi^2 N \therefore T_B \propto N$$

Obviously,  $T_B$  decreases as motor slows down and disappear altogether when it comes to a stop.

#### (b) Plugging or Reverse Current Braking

This method is commonly used in controlling elevators, rolling mills, printing presses and machine tools etc.

In this method, connections to the armature terminals are reversed so that motor tends to run in the opposite direction (Fig. 30.22). Due to the reversal of armature connections, applied voltage  $V$  and  $E_b$  start acting **in the same direction** around the circuit. In order to limit the armature current to a reasonable value, it is necessary to insert a resistor in the circuit while reversing armature connections.

Fig. 30.22

$$I_a = \frac{V + E_b}{R + R_a} = \frac{V}{R + R_a} + \frac{E_b}{R + R_a}$$

$$= \frac{V}{R + R_a} + \frac{\Phi Z N (P/A)}{R + R_a} = \frac{V}{R + R_a} + \frac{k_1 \Phi Z}{R + R_a}$$

$$T_B = \frac{1}{2\pi} \cdot \Phi Z I_a \left( \frac{P}{A} \right) = \frac{1}{2\pi} \cdot \left( \frac{\Phi Z P}{A} \right) \cdot I_a = \frac{1}{2\pi} \left( \frac{\Phi Z P}{A} \right) \left[ \frac{V}{R + R_a} + \frac{\Phi Z N (P/A)}{R + R_a} \right]$$

\* The motor while acting as a generator feeds current to the resistor dissipating heat at the rate of  $I_a^2 R$ . The current  $I_a$  produced by dynamic braking flow in the opposite direction, thereby producing a counter torque that slows down the machine.

$$= \frac{1}{2\pi} \left( \frac{ZP}{A} \right) \left( \frac{V}{R+R_a} \right) \cdot \Phi + \frac{1}{2\pi} \cdot \left( \frac{ZP}{A} \right)^2 \cdot \frac{\Phi^2 N}{R+R_a} = k_2 \Phi + k_3 \Phi^2 N$$

or  $T_b = k_4 + k_5 N$ , where  $k_4 = \frac{1}{2\pi} \left( \frac{\Phi ZP}{A} \right) \left( \frac{V}{R+R_a} \right)$

and  $k_5 = \frac{1}{2\pi} \left( \frac{\Phi ZP}{A} \right)^2 \times \frac{1}{(R+R_a)}$ .

Plugging gives greater braking torque than rheostatic braking. Obviously, during plugging, power is drawn from the supply and is dissipated by  $R$  in the form of heat. It may be noted that even when motor is reaching zero speed, there is some braking torque  $T_B = k_4$  (see Ex. 30.47).

**(c) Regenerative Braking**

This method is used when the load on the motor has overhauling characteristic as in the lowering of the cage of a hoist or the downgrade motion of an electric train. Regeneration takes place when  $E_b$  becomes greater than  $V$ . This happens when the overhauling

Regenerative braking demonstrations

load acts as a prime mover and so drives the machines as a generator. Consequently, direction of  $I_a$  and hence of armature torque is reversed and speed falls until  $E_b$  becomes lower than  $V$ . It is obvious that during the slowing down of the motor, power is returned to the line which may be used for supplying another train on an upgrade, thereby relieving the powerhouse of part of its load (Fig. 30.23).

Fig. 30.23

For protective purposes, it is necessary to have some type of mechanical brake in order to hold the load in the event of a power failure.

**Example 30.46.** A 220 V compensated shunt motor drives a 700 N-m torque load when running at 1200 r.p.m. The combined armature compensating winding and interpole resistance is 0.008 Ω and shunt field resistance is 55 Ω. The motor efficiency is 90%. Calculate the value of the dynamic braking resistor that will be capable of 375 N-m torque at 1050 r.p.m. The windage and friction losses may be assumed to remain constant at both speeds.

**Solution.** Motor output =  $\omega T = 2\pi NT = 2\pi (1200/60) \times 700 = 87,965 \text{ W}$

Power drawn by the motor =  $87,965/0.9 = 97,740 \text{ W}$

Current drawn by the motor =  $97,740/220 = 444 \text{ A}$ .

$I_{sh} = 220/55 = 4 \text{ A}$  ;  $I_{a1} = 444 - 4 = 440 \text{ A}$

$E_{b1} = 220 - 440 \times 0.008 = 216.5 \text{ V}$

Since field flux remains constant,  $T_1$  is proportional to  $I_{a1}$  and  $T_2$  to  $I_{a2}$ .

$\frac{T_2}{T_1} = \frac{I_{a2}}{I_{a1}}$  or  $I_{a2} = 440 \times \frac{375}{100} = 2650 \text{ A}$

$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}}$  or  $\frac{1050}{1200} = \frac{E_{b2}}{216.5}$  ;  $E_{b2} = 189.4 \text{ V}$

With reference to Fig. 30.23, we have

$189.4 = 2650 (0.008 + R)$  ;  $R = 0.794 \text{ } \Omega$

30.8. Electric Braking of Series Motor

The above-discussed three methods as applied to series motors are as follows :

(a) Rheostatic (or Dynamic) Braking

The motor is disconnected from the supply, the field connections **are reversed** and the motor is connected in series with a variable resistance  $R$  as shown in Fig. 30.24. Obviously, now, the machine is running as a generator.

The field connections are reversed to make sure that current through field winding is in the *same* direction as before (i.e., from  $M$  to  $N$ ) in order to assist residual magnetism. In practice, the variable resistance employed for starting purpose is itself used for braking purposes. As in the case of shunt motors,

Fig. 30.24

$$T_B = k_2 \Phi^2 N = k_3 I_a^2 N \quad \dots \text{prior to saturation}$$

(b) Plugging or Reverse Current Braking

As in the case of shunt motors, in this case also the connections of the armature are reversed and a variable resistance  $R$  is put in series with the armature as shown in Fig. 30.25. As found in Art. 30.7 (b),

$$T_B = k_2 \Phi + k_3 \Phi^2 N$$

(c) Regenerative Braking

This type of braking of a series motor is not possible without modification because reversal of  $I_a$  would also mean reversal of the field and hence of  $E_b$ . However, this method is sometimes used with traction motors, special arrangements being necessary for the purpose.

Fig. 30.25

**Example 30.47.** A 400 V, 25 h.p. (18.65 kW), 45 r.p.m., d.c. shunt motor is braked by plugging when running on full load. Determine the braking resistance necessary if the maximum braking current is not to exceed twice the full-load current. Determine also the maximum braking torque and the braking torque when the motor is just reaching zero speed. The efficiency of the motor is 74.6% and the armature resistance is 0.2  $\Omega$ . (Electrical Technology, M.S. Univ. Baroda, 1988)

**Solution.**

F.L. Motor input current	$I = 18,650/0.746 \times 400 = 62.5 \text{ A}$
$I_a = 62.5 \text{ A}$ (neglecting $I_{sh}$ );	$E_b = 400 - 62.5 \times 0.2 = 387.5 \text{ V}$
Total voltage around the circuit is	$= 400 + 387.5 = 787.5 \text{ V}$
Max. braking current	$= 2 \times 62.5 = 125 \text{ A}$
Total resistance required in the circuit	$= 787.5/125 = 6.3 \Omega$
Braking resistance	$R = 6.3 - 0.2 = 6.1 \Omega$

Maximum braking torque will be produced initially when the motor speed is maximum i.e., 450 r.p.m. or 7.5 r.p.s.

Maximum value of  $T_B = k_4 + k_5 N$  – Art. 25.7(b)

Now, 
$$k_4 = \frac{1}{2\pi} \left( \frac{\Phi Z P}{A} \right) \left( \frac{V}{R + R_a} \right) \text{ and } k_5 = \frac{1}{2\pi} \left( \frac{\Phi Z P}{A} \right)^2 \cdot \frac{1}{(R + R_a)}$$

Now,  $E_b = \Phi ZN (P/A)$  ; also  $N = 450/60 = 7.5$  r.p.s.  
 $\therefore 387.5 = 7.5 (\Phi ZP/A)$  or  $(\Phi ZP/A) = 51.66$   
 $\therefore k_4 = \frac{1}{2\pi} \times 51.66 \times \frac{400}{6.3} = 522$  and  $k_5 = \frac{1}{2\pi} \times (51.66)^2 \times \frac{1}{6.3} = 67.4$   
 $\therefore$  Maximum  $T_B = 522 + 67.4 \times 7.5 = 1028$  N-m

When speed is also zero *i.e.*,  $N = 0$ , the value of torque is  $T_B = K_4 = 522$  N-m.

### 30.9. Electronic Speed Control Method for DC Motors

Of late, solid-state circuits using semiconductor diodes and thyristors have become very popular for controlling the speed of a.c. and d.c. motors and are progressively replacing the traditional electric power control circuits based on thyratrons, ignitrons, mercury arc rectifiers, magnetic amplifiers and motor-generator sets etc. As compared to the electric and electromechanical systems of speed control, the electronic methods have higher accuracy, greater reliability, quick response and also higher efficiency as there are no  $I^2R$  losses and moving parts. Moreover, full 4-quadrant speed control is possible to meet precise high-speed standards.

All electronic circuits control the motor speed by adjusting either (i) the voltage applied to the motor armature or (ii) the field current or (iii) both.

DC motors can be run from d.c. supply if available or from a.c. supply after it has been converted into d.c. supply with the help of rectifiers which can be either half-wave or full-wave and either controlled (by varying the conduction angle of the thyristors used) or uncontrolled.

AC motors can be run on the a.c. supply or from d.c. supply after it has been converted into a.c. supply with the help of inverters (opposite of rectifiers).

As stated above, the average output voltage of a thyristor-controlled rectifier can be changed by changing its conduction angle and hence the armature voltage of the d.c. motor can be adjusted to control its speed.

When run on a d.c. supply, the armature d.c. voltage can be changed with the help of a thyristor chopper circuit which can be made to interrupt d.c. supply at different rates to give different average values of the d.c. voltage. If d.c. supply is not available, it can be obtained from the available a.c. supply with the help of uncontrolled rectifiers (using only diodes and not thyristors). The d.c. voltages so obtained can be then chopped with the help of a thyristor chopper circuit.

A brief description of rectifiers, inverters\* and d.c. choppers would now be given before discussing the motor speed control circuits.

### 30.10. Uncontrolled Rectifiers

As stated earlier, rectifiers are used for a.c. to d.c. conversion *i.e.*, when the supply is alternating but the motor to be controlled is a d.c. machine.

Fig. 30.26 (a) shows a half-wave uncontrolled rectifier. The diode  $D$  conducts only during positive half-cycles of the single-phase a.c. input *i.e.*, when its anode  $A$  is positive with respect to its cathode  $K$ . As shown, the average voltage available across the load (or motor) is  $0.45 V$  where  $V$  is the r.m.s. value of the a.c. voltage (in fact,  $V = V_m / \sqrt{2}$ ). As seen it is a pulsating d.c. voltage.

In Fig. 30.26 (b) a single-phase, full-wave bridge rectifier which uses four semiconductor diodes and provides double the voltage *i.e.*,  $0.9 V$  is shown. During positive input half-cycles when end  $A$  is positive with respect to end  $B$ , diodes  $D_1$  and  $D_4$  conduct (*i.e.* opposite diodes) whereas during negative input half-cycles,  $D_2$  and  $D_3$  conduct. Hence, current flows through the load during both half-cycles in the *same* direction. As seen, the d.c. voltage supplied by a bridge rectifier is much less pulsating than the one supplied by the half-wave rectifier.

\* Rectifiers convert a.c. power into d.c. power, whereas inverters convert d.c. power into a.c. power. However, converter is a general term embracing both rectifiers and inverters.

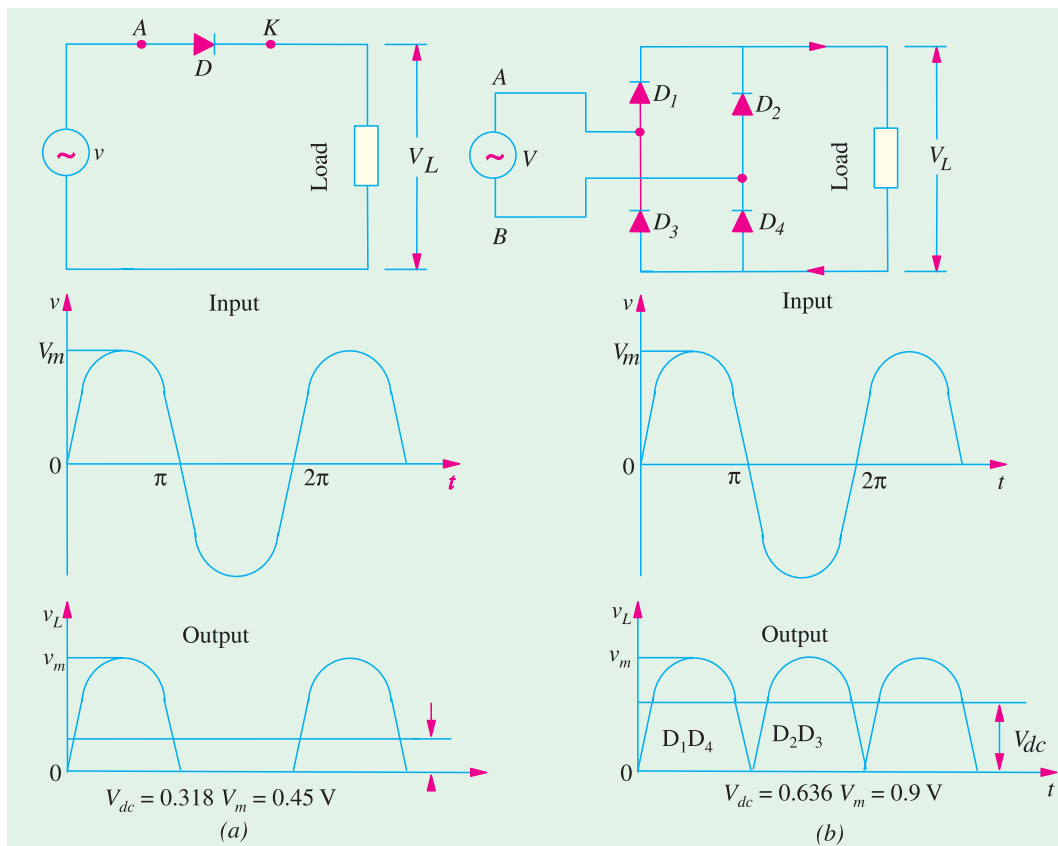

Fig. 30.26

### 30.11. Controlled Rectifiers

In these rectifiers, output load current (or voltage) can be varied by controlling the point in the input a.c. cycle at which the thyristor is turned ON with the application of a suitable low-power gate pulse. Once triggered (or fired) into conduction, the thyristor remains in the conducting state for the rest of the half-cycle *i.e.*, upto  $180^\circ$ . The firing angle  $\alpha$  can be adjusted with the help of a control circuit. When conducting, it offers no resistance *i.e.*, it acts like a short-circuit.

Fig. 30.27 (a) shows an elementary half-wave rectifier in which thyristor triggering is delayed by angle  $\alpha$  with the help of a phase-control circuit. As shown, the thyristor starts conducting at point A and not at point O because its gate pulse is applied after a delay of  $\alpha$ . Obviously, the conduction angle is reduced from  $180^\circ$  to  $(180^\circ - \alpha)$  with a consequent decrease in output voltage whose value is given by

$$V_L = \frac{V_m}{2\pi} (1 + \cos \alpha) = 0.16 V_m (1 + \cos \alpha) = 0.32 V_m \cos^2 \frac{\alpha}{2}$$

where  $V_m$  is the peak value of a.c. input voltage. Obviously,  $V_L$  is maximum when  $\alpha = 0$  and is zero when  $\alpha = 180^\circ$ .

Fig. 30.27 (b) shows the arrangement where a thyristor is used to control current through a load connected in series with the a.c. supply line.

Fig. 30.27

The load current is given by

$$I_L = \frac{V_L}{R_L} = \frac{V_m}{2\pi R_L} (1 + \cos \alpha) = \frac{V_m}{\pi R_L} \cos^2 \frac{\alpha}{2}$$

Fig. 30.28 (a) shows a single-phase, full-wave half-controlled rectifier. It is called half-controlled because it uses two thyristors and two diodes instead of four thyristors. During positive input half-cycle when A is positive, conduction takes place via  $T_1$ , load and  $D_1$ . During the negative half-cycle when B becomes positive, conduction route is via  $T_2$ , load and  $D_2$ .

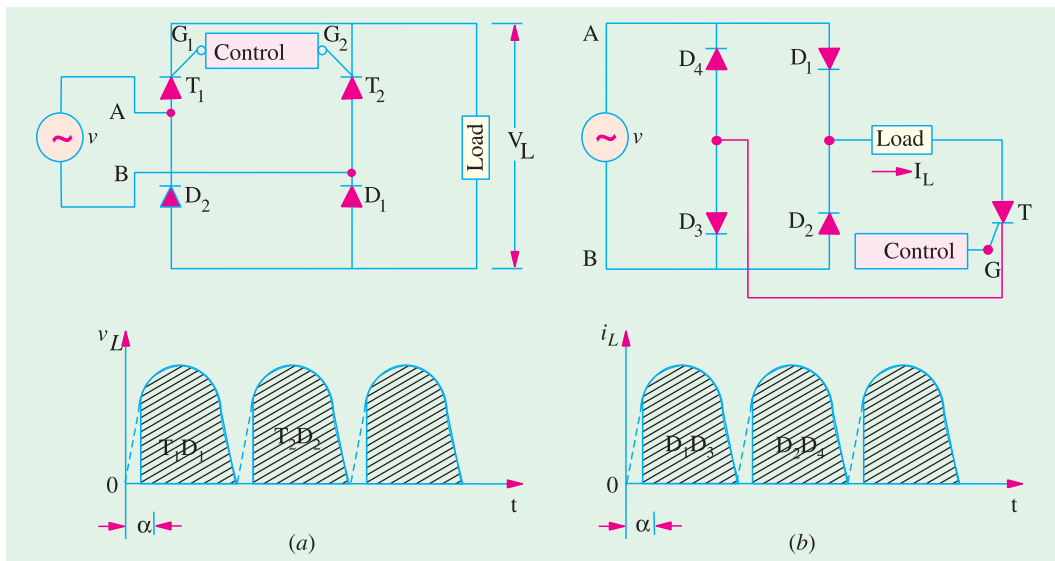

Fig. 30.28

The average output voltage  $V_L$  or  $V_{dc}$  is given by  $V_L = 2 \times$  half-wave rectifier output

$$\therefore V_L = 2 \times \frac{V_m}{2\pi} (1 + \cos \alpha) = \frac{V_m}{\pi} (1 + \cos \alpha) = \frac{2V_m}{\pi} \cos^2 \frac{\alpha}{2}$$

Similarly, Fig. 30.28 (b) shows a 4-diode bridge rectifier controlled by a single thyristor. The average load current through the series load is given by

$$I_L = \frac{V_m}{\pi R_L} (1 + \cos \alpha) = \frac{2V_m}{\pi R_L} \cos^2 \frac{\alpha}{2}$$

As seen from the figure, when  $A$  is positive,  $D_1$  and  $D_3$  conduct provided  $T$  has been fired. In the negative half-cycle,  $D_2$  and  $D_4$  conduct via the load.

### 30.12. Thyristor Choppers

Since thyristors can be switched ON and OFF very rapidly, they are used to interrupt a d.c. supply at a regular frequency in order to produce a lower (mean) d.c. voltage supply. In simple words, they can produce low-level d.c. voltage from a high-voltage d.c. supply as shown in Fig. 30.29.

The mean value of the output voltage is given by

$$V_{dc} = V_L = V \frac{T_{ON}}{T_{ON} + T_{OFF}} = V \frac{T_{ON}}{T}$$

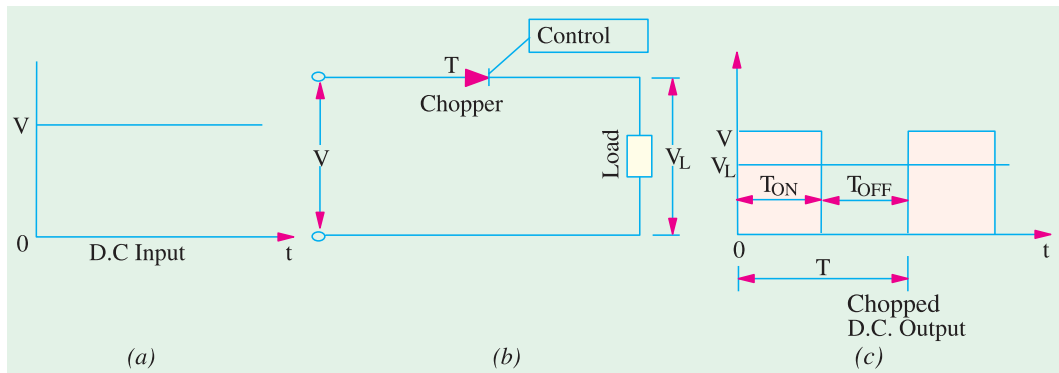

Fig. 30.29

Fig. 30.30 (a) shows a simple thyristor chopper circuit along with extra commutating circuitry for switching  $T_1$  OFF. As seen,  $T_1$  is used for d.c. chopping, whereas  $R$ ,  $T_2$  and  $C$  are used for commutation purposes as explained below.

When  $T_1$  is fired into conduction by its control circuit (not shown), current is set up through the load and commutation capacitor  $C$  gets charged via  $R$  with the polarity shown in the figure during this ON period.

For switching  $T_1$  OFF, second thyristor  $T_2$  is triggered into conduction allowing  $C$  to discharge through it (since it acts as a short-circuit while conducting) which reverse-biases  $T_1$  thus turning it OFF. The discharge from  $C$  leaves  $T_2$  with reverse polarity so that it is turned OFF, whereas  $T_1$  is triggered into conduction again.

Depending upon the frequency of switching ON and OFF, the input d.c. voltage is cut into d.c. pulses as shown in Fig. 30.30 (c).

\* For a fully-controlled bridge rectifier, its value is

$$V_L = \frac{2V_m}{\pi} \cos \alpha .$$

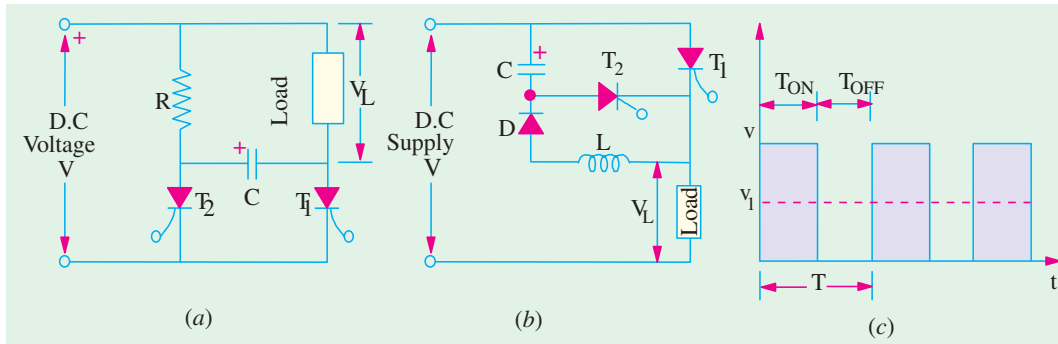

Fig. 30.30

In Fig. 30.30 (b),  $T_1$  is the chopping thyristor, whereas  $C, D, T_2$  and  $L$  constitute the commutation circuitry for switching  $T_1$  OFF and ON at regular intervals.

When  $T_2$  is fired,  $C$  becomes charged via the load with the polarity as shown. Next, when  $T_1$  is fired,  $C$  reverse-biases  $T_2$  to OFF by discharging via  $T_1, L$  and  $D$  and then recharges with reverse polarity.  $T_2$  is again fired and the charge on  $C$  reverse-biases  $T_1$  to non-conducting state.

It is seen that output (or load) voltage is present only when  $T_1$  is ON and is absent during the interval it is OFF. The mean value of output d.c. voltage depends on the relative values of  $T_{ON}$  and  $T_{OFF}$ . In fact, output d.c. voltage is given by

$$V_{dc} = V_L \frac{T_{ON}}{T_{ON} + T_{OFF}} = V \frac{T_{ON}}{T}$$

Obviously, by varying thyristor ON/OFF ratio,  $V_L$  can be made any percentage of the input d.c. voltage  $V$ .

**Example 30.48.** The speed of a separately excited d.c. motor is controlled by a chopper. The supply voltage is 120 V, armature circuit resistance = 0.5 ohm, armature circuit inductance = 20 mH and motor constant = 0.05 V/r.p.m. The motor drives a constant load torque requiring an average current of 20 A. Assume motor current is continuous. Calculate (a) the range of speed control (b) the range of duty cycle. (Power Electronics-I, Punjab Univ. Nov. 1990)

**Solution.** The minimum speed is zero when  $E_b = 0$

$$V_t = E_b + I_a R_a = I_a \times R_a = 200 \times 0.5 = 10 \text{ V}$$

Now, 
$$V_t = \frac{V \alpha}{1 - \alpha} \Rightarrow 10 = \frac{120 \alpha}{1 - \alpha} \Rightarrow \alpha = \frac{1}{12}$$

Maximum speed corresponds to  $\alpha = 1$  when  $V_t = V = 120 \text{ V}$

$\therefore E_b = 120 - 20 \times 0.5 = 110 \text{ V}$

Now, 
$$N = E_b / K_a \Phi = 110 / 0.05 = 2200 \text{ r.p.m.}$$

(a) Hence, speed range is from 0 to 2200 r.p.m.

(b) Range of duty cycle is from  $\frac{1}{12}$  to 1.

### 30.13. Thyristor Inverters

Such inverters provide a very efficient and economical way of converting direct current (or voltage) into alternating current (or voltage). In this application, a thyristor serves as a controlled switch alternately opening and closing a d.c. circuit. Fig. 30.31 (a), shows a basic inverter circuit where an a.c. output is obtained by alternately opening and closing switches  $S_1$  and  $S_2$ . When we

replace the mechanical switches by two thyristors (with their gate triggering circuits), we get the thyristor inverter in Fig. 30.31 (b).

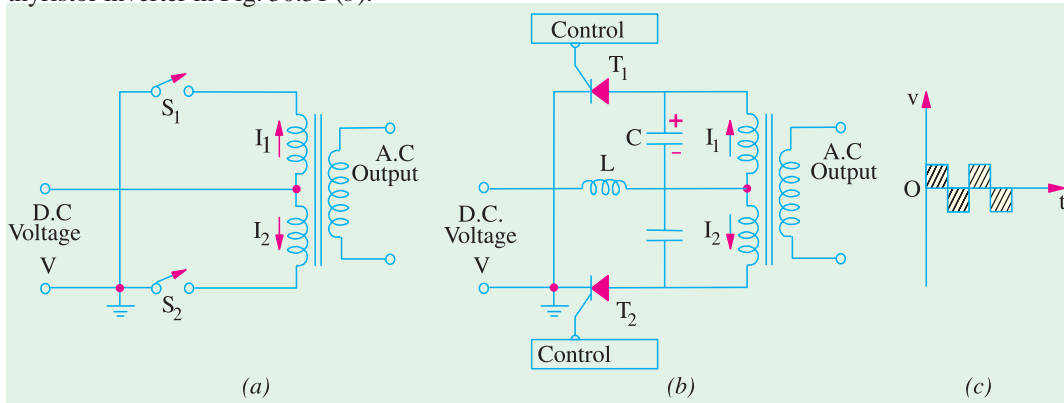

Fig. 30.31

Before discussing the actual circuit, it is worthwhile to recall that thyristor is a latching device which means that once it starts conducting, gate loses control over it and cannot switch it OFF whatever the gate signal. A separate **commutating** circuitry is used to switch the thyristor OFF and thus enable it to perform ON-OFF switching function.

Suppose  $T_1$  is fired while  $T_2$  is still OFF. Immediately  $I_1$  is set up which flows through  $L$ , one half of transformer primary and  $T_1$ . At the same time,  $C$  is charged with the polarity as shown.

Next when  $T_2$  is fired into condition,  $I_2$  is set up and  $C$  starts discharging through  $T_1$  thereby reverse-biasing it to CUT-OFF.

When  $T_1$  is again pulsed into condition,  $I_1$  is set up and  $C$  starts discharging thereby reverse-biasing  $T_2$  to OFF and the process just described repeats. As shown in Fig. 30.31 (c), the output is an alternating voltage whose frequency depends on the switching frequency to thyristors  $T_1$  and  $T_2$ .

Second generation thyristor inverter

### 30.14. Thyristor Speed Control of Separately-excited D.C. Motor

In Fig. 30.32, the bridge rectifier converts a voltage into d.c. voltage which is then applied to the armature of the separately-excited d.c. motor  $M$ .

As we know, speed of a motor is given by

$$N = \frac{V - I_a R_a}{\Phi} \left( \frac{A}{ZP} \right)$$

If  $\Phi$  is kept constant and also if  $I_a R_a$  is neglected, then,  $N \propto V \propto$  voltage across the armature. The value of this voltage furnished by the rectifier can be changed by varying the firing angle  $\alpha$  of the thyristor  $T$  with the help of its control circuit. As  $\alpha$  is increased *i.e.*, thyristor firing is delayed

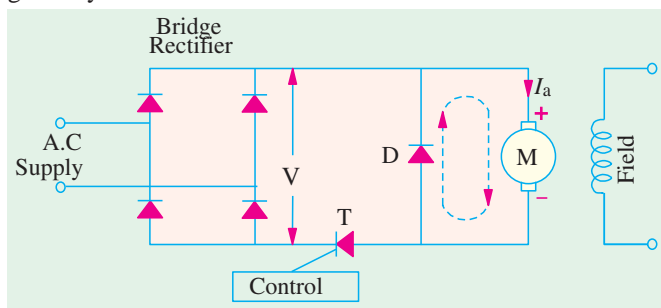

Fig. 30.32

more, its conduction period is reduced and, hence, armature voltage is decreased which, in turn, decreases the motor speed. When  $\alpha$  is decreased *i.e.*, thyristor is fired earlier, conduction period is increased which increases the mean value of the voltage applied across the motor armature. Consequently, motor speed is increased. In short, as  $\alpha$  increases,  $V$  decreases and hence  $N$  decreases. Conversely, as  $\alpha$  decreases,  $V$  increases and so,  $N$  increases. The free-wheeling diode  $D$  connected across the motor provides a circulating current path (shown dotted) for the energy stored in the inductance of the armature winding at the time  $T$  turns OFF. Without  $D$ , current will flow through  $T$  and bridge rectifier, prohibiting  $T$  from turning OFF.

### 30.15. Thyristor Speed Control of a D.C. Series Motor

In the speed control circuit of Fig. 30.33, an  $RC$  network is used to control the diac voltage that triggers the gate of a thyristor. As the a.c. supply is switched ON, thyristor  $T$  remains OFF but the capacitor  $C$  is charged through motor armature and  $R$  towards the peak value of the applied a.c. voltage. The time it takes for the capacitor voltage  $V_C$  to reach the breakover voltage of the diac\* depends on the setting of the variable resistor  $T$ . When  $V_C$  becomes equal to the breakover voltage of diac, it conducts and a triggering pulse is applied to the thyristor gate  $G$ . Hence,  $T$  is turned ON and allows current to pass through the motor. Increasing  $R$  delays the rise of  $V_C$  and hence the breakover of diac so that thyristor is fired later in each positive half cycle of the a.c. supply. It reduces the conduction angle of the thyristor which, consequently, delivers less power to the motor. Hence, motor speed is reduced.

If  $R$  is reduced, time-constant of the  $RC$  network is decreased which allows  $V_C$  to rise to the breakover voltage of diac more quickly. Hence, it makes the thyristor fire early in each positive input half-cycle of the supply. Due to increase in the conduction angle of the thyristor, power delivered to the motor is increased with a subsequent increase in its speed. As before  $D$  is the free-wheeling diode which provides circulating current path for the energy stored in the inductance of the armature winding.

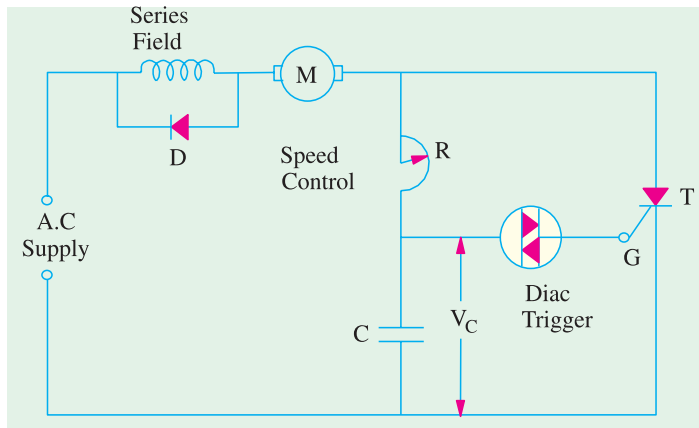

Fig. 30.33

### 30.16. Full-wave Speed Control of a Shunt Motor

Fig. 30.34 shows a circuit which provides a wide range of speed control for a fractional kW shunt d.c. motor. The circuit uses a bridge circuit for full-wave rectification of the a.c. supply. The shunt field winding is permanently connected across the d.c. output of the bridge circuit. The armature voltage is supplied through thyristor  $T$ . The magnitude of this

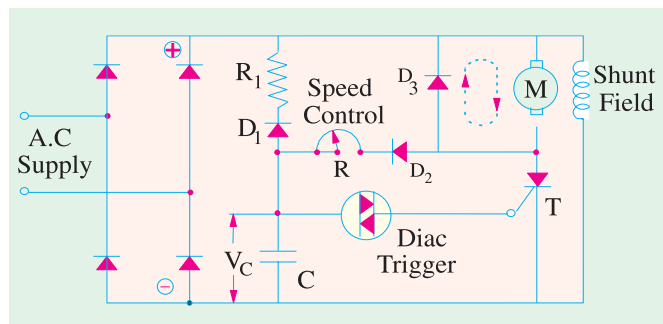

Fig. 30.34

\* Like a triac, it has directional switching characteristics.

voltage (and hence, the motor speed) can be changed by turning  $T_{ON}$  at different points in each half-cycle with the help of  $R$ . The thyristor turns OFF only at the end of each half-cycle. Free-wheeling diode  $D_3$  provides a circulating current path (shown dotted) for the energy stored in the armature winding at the time  $T$  turns OFF. Without  $D_3$ , This current would circulate through  $T$  and the bridge rectifier thereby prohibiting  $T$  from turning OFF.

At the beginning of each half-cycle,  $T$  is the OFF state and  $C$  starts charging up via motor armature, diode  $D_2$  and speed-control variable resistor  $R$  (it cannot charge through  $R_1$  because of reverse-biased diode  $D_1$ ). When voltage across  $C$  i.e.,  $V_C$  builds up to the breakover voltage of diac, diac conducts and applies a sudden pulse to  $T$  thereby turning it ON. Hence, power is supplied to the motor armature for the remainder of that half-cycle. At the end of each half-cycle,  $C$  is discharged through  $D_1, R_1$  and shunt field winding. The delay angle  $\alpha$  depends on the time it takes  $V_C$  to become equal to the breakover voltage of the diac. This time, in turn, depends on the time-constant of the  $R$ - $C$  circuit and the voltage available at point  $A$ . By changing  $R$ ,  $V_C$  can be made to build-up either slowly or quickly and thus change the angle  $\alpha$  at will. In this way, the average value of the d.c. voltage across the motor armature can be controlled. It further helps to control the motor speed because it is directly proportional to the armature voltage.

Now, when load is increased, motor tends to slow down. Hence,  $E_b$  is reduced. The voltage of point  $A$  is increased because it is equal to the d.c. output voltage of the bridge rectifier *minus* back e.m.f.  $E_b$ . Since  $V_A$  increases i.e., voltage across the  $R$ - $C$  charging circuit increases, it builds up  $V_C$  more quickly thereby decreasing which leads to early switching ON of  $T$  in each half-cycle. As a result, power supplied to the armature is increased which increases motor speed thereby compensating for the motor loading.

### 30.17. Thyristor Speed Control of a Shunt Motor

The speed of a shunt d.c. motor (upto 5 kW) may be regulated over a wide range with the help of the full-wave rectifier using only one main thyristor (or SCR)  $T$  as shown in Fig. 30.35. The firing angle  $\alpha$  of  $T$  is adjusted by  $R_1$  thereby controlling the motor speed. The thyristor and  $SUS$  (silicon unilateral switch) are reset (i.e., stop conduction) when each half-wave of voltage drops to zero. Before switching on the supply,  $R_1$  is increased by turning it in the counter-clockwise direction. Next, when supply is switched ON,  $C$  gets charged via motor armature and diode  $D_1$  (being forward biased). It means that it takes much longer for  $V_C$  to reach the breakdown voltage of  $SUS^*$  due to large time constant of  $R_1$ - $C$  network. Once  $V_C$  reaches that value,  $SUS$  conducts suddenly and triggers  $T$  into conduction. Since thyristor starts conducting late (i.e., its  $\alpha$  is large), it furnishes low voltage to start the motor. As speed selector  $R_1$  is turned clockwise (for less resistance),  $C$  charges up more rapidly (since time constant is decreased) to the breakover voltage of  $SUS$  thereby firing  $T$  into conduction earlier. Hence, average value of the d.c. voltage across the motor armature increases thereby increasing its speed.

While the motor is running at the speed set by  $R_1$ , suppose that load on the motor is increased. In that case, motor will tend to slow down thereby decreasing armature back e.m.f. Hence, potential of point 3 will rise which will charge  $C$  faster to the breakover voltage of  $SUS$ . Hence, thyristor will be fired earlier thereby applying greater armature voltage which will return the motor speed to its desired value. As seen, the speed is automatically regulated to offset changes in load.

The function of free-wheeling diode  $D_2$  is to allow dissipation of energy stored in motor

Fig. 30.35

\* It is a four-layer semiconductor diode with a gate terminal. Unlike diac, it conducts in one direction only.

armature during the time the full-wave rectified voltage drops to zero between half-cycles. If  $D_2$  is not there, then decreasing armature current during those intervals would be forced to flow through  $T$  thereby preventing its being reset. In that case,  $T$  would not be ready to be fired in the next half-cycle.

Similarly, towards the end of each half cycle as points 1 and 5 decrease towards zero potential, the negative going gate  $G$  turns  $SUS$  on thereby allowing  $C$  to discharge completely through  $SUS$  and thyristor gate-cathode circuit so that it can get ready to be charged again in the next half-cycle.

### 30.18. Thyristor Speed Control of a Series D.C. Motor

Fig. 30.36 shows a simple circuit for regulating the speed of a d.c. motor by changing the average value of the voltage applied across the motor armature by changing the thyristor firing angle  $\alpha$ . The trigger circuit  $R_1 - R_2$  can give a firing range of almost  $180^\circ$ . As the supply is switched on, full d.c. voltage is applied across  $R_1 - R_2$ . By changing the variable resistance  $R_2$ , drop across it can be made large enough to fire the SCR at any desired angle from  $0^\circ - 180^\circ$ . In this way, output voltage of the bridge rectifier can be changed considerably, thus enabling a wide-range control of the motor speed. The speed control can be made somewhat smoother by joining a capacitor  $C$  across  $R_2$  as shown in the figure.

Fig. 30.36

### 30.19. Necessity of a Starter

It has been shown in Art 29.3 that the current drawn by a motor armature is given by the relation

$$I_a = (V - E_b)/R_a$$

where  $V$  is the supply voltage,  $E_b$  the back e.m.f. and  $R_a$  the armature resistance.

When the motor is at rest, there is, as yet, obviously no back e.m.f. developed in the armature. If, now, full supply voltage is applied across the stationary armature, it will draw a very large current because armature resistance is relatively small. Consider the case of a 440-V, 5 H.P. (3.73 kW) motor having a cold armature resistance of  $0.25 \Omega$  and a full-load current of 50 A. If this motor is started from the line directly, it will draw a starting current of  $440/0.25 = 1760 \text{ A}$  which is  $1760/50 = 35.2$  times its full-load current. This excessive current will blow out the fuses and, prior to that, it will damage the commutator and brushes etc. To avoid this happening, a resistance is introduced in series with the armature (for the duration of starting period only, say 5 to 10 seconds) which limits the starting current to a safe value. The starting resistance is gradually cut out as the motor gains speed and develops the back e.m.f. which then regulates its speed.

Fig. 30.37

Very small motors may, however, be started from rest by connecting them directly to the supply lines. It does not result in any harm to the motor for the following reasons :

1. Such motors have a relatively higher armature resistance than large motors, hence their starting current is not so high.
2. Being small, they have low moment of inertia, hence they speed up quickly.
3. The momentary large starting current taken by them is not sufficient to produce a large disturbance in the voltage regulation of the supply lines.

In Fig. 30.37 the resistance  $R$  used for starting a shunt motor is shown. It will be seen that the starting resistance  $R$  is in series with the **armature** and not with the **motor** as a whole. The field winding is connected directly across the lines, hence shunt field current is independent of the

resistance  $R$ . If  $R$  was introduced in the motor circuit, then  $I_{sh}$  will be small at the start, hence starting torque  $T_{st}$  would be small ( $\because T_a \propto \Phi I_a$ ) and there would be experienced some difficulty in starting the motor. Such a simple starter is shown diagrammatically in Fig. 30.38.

Fig. 30.38

### 30.20. Shunt Motor Starter

The face-plate box type starters used for starting shunt and compound motors of ordinary industrial capacity are of two kinds known as three-point and four-point starters respectively.

### 30.21. Three-point Starter

The internal wiring for such a starter is shown in Fig. 30.39 and it is seen that basically the connections are the same as in Fig. 30.37 except for the additional protective devices used here. The three terminals of the starting box are marked  $A$ ,  $B$  and  $C$ . One line is directly connected to one armature terminal and one field terminal which are tied together. The other line is connected to point  $A$  which is further connected to the starting arm  $L$ , through the overcurrent (or overload) release  $M$ .

To start the motor, the main switch is first closed and then the starting arm is slowly moved to the right. As soon as the arm makes contact with stud No. 1, the field circuit is directly connected across the line and at the same time full starting resistance  $R$ , is placed in series with the armature. The starting current drawn by the armature =  $V/(R_a + R_s)$  where  $R_s$  is the starting

Fig. 30.39

Fig. 30.40

which is connected to stud No. 1 (Fig. 30.40). The field circuit is completed through the starting resistance as it did in Fig. 30.39.

Now, we will discuss the action of the two protective devices shown in Fig. 30.39. The normal function of the HOLD-ON coil is to hold on the arm in the full running position when the motor is in normal operation. But, in the case of failure or disconnection of the supply or a break in the field circuit, it is de-energised, thereby releasing the arm which is pulled back by the spring to the OFF position. This prevents the stationary armature from being put across the lines again when the supply is restored after temporary shut down. This would have happened if the arm were left in the full ON position. One great advantage of connecting the HOLD-ON coil in series with the shunt field is that, should the field circuit become open, the starting arm immediately springs back to the OFF position thereby preventing the motor from running away.

The overcurrent release consists of an electromagnet connected in the supply line. If the motor becomes overloaded beyond a certain predetermined value, then *D* is lifted and short circuits the electromagnet. Hence, the arm is released and returns to OFF position.

The form of overload protection described above is becoming obsolete, because it cannot be made either as accurate or as reliable as a separate well-designed circuit breaker with a suitable time element attachment. Many a times a separated magnetic contactor with an overload relay is also used.

Often the motors are protected by thermal overload relays in which a bimetallic strip is heated by the motor current at approximately the same rate at which the motor is itself heating up. Above a certain temperature, this relay trips and opens the line contactor, thereby isolating the motor from the supply.

If it is desired to control the speed of the motor in addition, then a field rheostat is connected in the field circuit as indicated in Fig. 30.39. The motor speed can be increased by weakening the flux ( $\mathcal{E} N \propto I/\Phi$ ). Obviously, there is a limit to the speed increase obtained in this way, although speed ranges of three to four are possible. The connections of a starter and speed regulator with the motor are shown diagrammatically in Fig. 30.41. But there is one difficulty with such an arrangement for speed control. If too much resistance is 'cut in' by the field rheostat, then field current is reduced very much so that it is unable to create enough electromagnetic pull to overcome the spring tension. Hence,

resistance. As the arm is further moved, the starting resistance is gradually cut out till, when the arm reaches the running position, the resistance is all cut out. The arm moves over the various studs against a strong spring which tends to restore it to OFF position. There is a soft iron piece *S* attached to the arm which in the full 'ON' or running position is attracted and held by an electromagnet *E* energised by the shunt current. It is variously known as 'HOLD-ON' coil, LOW VOLTAGE (or NO-VOLTAGE) release.

It will be seen that as the arm is moved from stud NO. 1 to the last stud, the field current has to travel back through that portion of the starting resistance that has been cut out of the armature circuit. This results in slight decrease of shunt current. But as the value of starting resistance is very small as compared to shunt field resistance, this slight decrease in  $I_{sh}$  is negligible. This defect can, however, be remedied by using a brass arc

the arm is pulled back to OFF position. It is this undesirable feature of a three-point starter which makes it unsuitable for use with variable-speed motors. This has resulted in widespread application of four-point starter discussed below.

Fig. 30.41

### 30.22. Four-point Starter

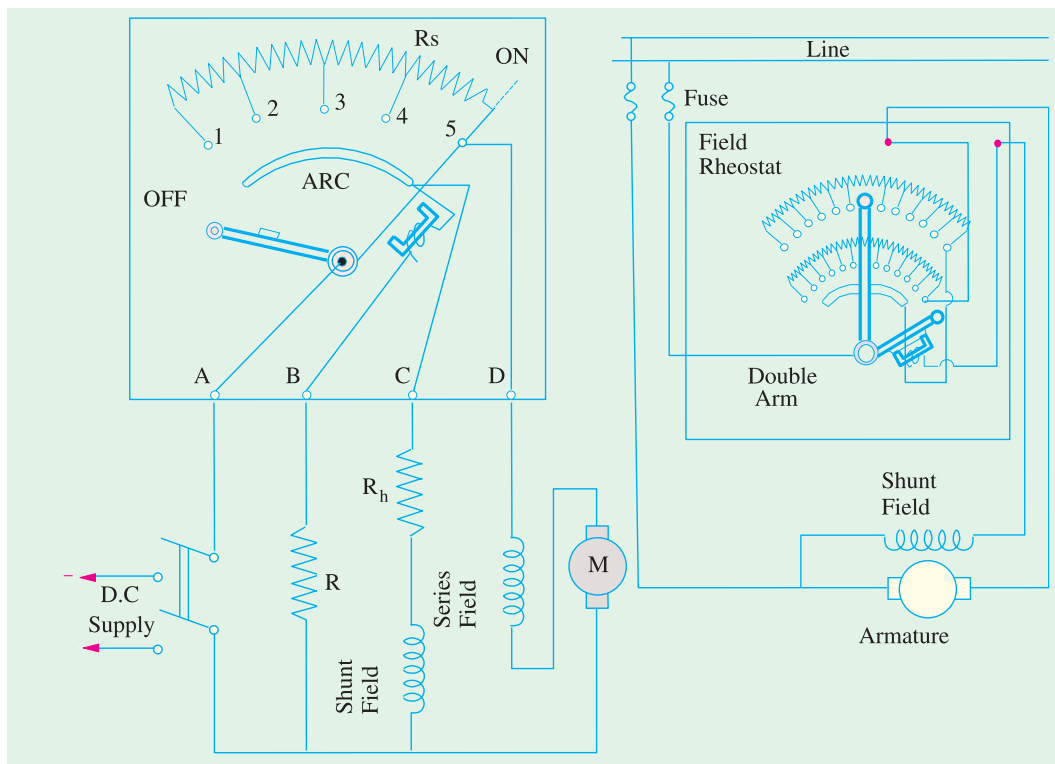

Fig. 30.42

Fig. 30.43

Such a starter with its internal wiring is shown, connected to a long-shunt compound motor in Fig. 30.42. When compared to the three-point starter, it will be noticed that one important change has been made *i.e.*, the HOLD-ON coil has been taken out of the shunt field circuit and has been connected directly across the line through a protecting resistance as shown. When the arm touches stud No. 1, then the line current divides into three parts (*i*) one part passes through starting resistance  $R_s$ , series field and motor armature (*ii*) the second part passes through the shunt field and its field rheostat  $R_f$  and (*iii*) the third part passes through the HOLD-ON coil and current-protecting resistance  $R$ . It should be particularly noted that with this arrangement any change of current in the shunt field circuit does not at all affect the current passing through the HOLD-ON coil because the two circuits are independent of each other. It means that the electromagnetic pull exerted by the HOLD-ON coil will always be sufficient and will prevent the spring from restoring the starting arm to OFF position no matter how the field rheostat or regulator is adjusted.

### 30.23. Starter and Speed-control Rheostats

Sometimes, for convenience, the field rheostat is also contained within the starting box as shown in Fig. 30.43. In this case, two arms are used. There are two rows of studs, the lower ones being connected to the armature. The inside starting arm moves over the lower studs on the starting resistor,

Speed-control Rheostats

whereas the outside field lever moves over the upper ones on the field rheostat. Only the outside field arm is provided with an operating handle. While starting the motor, the two arms are moved together, but field lever is electrically inoperative because the field current flows directly from the starting arm through the brass arc to HOLD-ON coil and finally to the shunt field winding. At the end of the starting period, the starting arm is attracted and held in FULL-ON position by the HOLD-ON coil, and the contact between the starting arm and brass arc is broken thus forcing field current to pass through the field rheostat. The

field lever can be moved back to increase the motor speed. It will be seen that now the upper row of contacts is operative because starting arm no longer touches the brass arc.

When motor is stopped by opening the main switch, the starting arm is released and on its way back it strikes the field lever so that both arms are returned simultaneously to OFF position.

### 30.24. Starting and Speed Control of Series Motor

For starting and speed control of series motor either a face-plate type or drum-type controller is used which usually has the reversing feature also. A face-plate type of reversing controller is shown in Fig. 30.44.

Except for a separate overload circuit, no inter-locking or automatic features are required because the operator watches the performance continuously.

As shown, the regulating lever consists of three pieces separated by strips of insulation. The outside parts form the electrical connections and the middle one is insulated from them. By moving the regulating lever, resistance can be cut in and out of the motor circuit. Reversing is obtained by moving the lever in the opposite direction as shown, because in that case, connections to the armature are reversed. Such an arrangement is employed where series motors are used as in the case of cranes, hoists and streetcars etc.

Fig. 30.44

circuit at this stage, then when resistance in the armature circuit is completely cut out, further rotation of the handle inserts resistance into the field circuit. Turning of the handle in the opposite direction starts and speeds up the motor in the reverse direction.

### 30.25. Grading of Starting Resistance for Shunt Motors

$T_{st}$  would be small in designing shunt motor starters, it is usual to allow an overload of 50% for starting and to advance the starter a step when armature current has fallen to definite lower value. Either this lower current limit may be fixed or the number of starter steps may be fixed. In the former case, the number of steps are so chosen as to suit the upper and lower current limits whereas in the latter case, the lower current limit will depend on the number of steps specified. It can be shown that the resistances in the circuit on successive studs from geometrical progression, having a common ratio equal to lower current limit/upper current limit i.e.,  $I_2/I_1$ .

In Fig. 30.45 the starter connected to a shunt motor is shown. For the sake of simplicity, four live studs have been taken. When arm A makes contact with stud No. 1, full shunt field is

However, for adjustable speed service in connection with the operation of machine tools, a drum controller is preferred. It is called 'controller' because in addition to accelerating the motor to its normal speed, it provides the means for reversing the direction of the motor. Other desirable features such as safety protection against an open field or the temporary failure of power supply and overloads are frequently provided in this type of controller.

The controller consists of armature resistance grids of cross-section sufficient to carry the full-load operating current continuously and are used for adjusting the motor speed to values lower than the base speed obtained with no external resistance in the armature of field circuit. As the operating handle is gradually turned, the resistance is cut out of the armature circuit—there being as yet no resistance in the field cir-

Fig. 30.45

Fig. 30.46

established and at the same time the armature current immediately jumps to a maximum value  $I_1$  given by  $I_1 = V/R_1$  where  $R_1 =$  armature and starter resistance (Fig. 30.45).

$I_1$  the maximum permissible armature current at the start ( $I_{max}$ ) and is, as said above, usually limited to 1.5 times the full-load current of the motor. Hence, the motor develops 1.5 times its full-load torque and accelerates very rapidly. As the motor speeds up, its back e.m.f. grows and hence decreases the armature current as shown by curve  $ab$  in Fig. 30.46.

When the armature current has fallen to some predetermined value  $I_2$  (also called  $I_{min}$ ) arm  $A$  is moved to stud No. 2. Let the value of back e.m.f. be  $E_{b1}$  at the time of leaving stud No. 1. Then

$$I_2 = \frac{V - E_{b1}}{R_1} \quad \dots(i)$$

It should be carefully noted that  $I_1$  and  $I_2$  [ $(I_{max})$  and  $(I_{min})$ ] are respectively the maximum and minimum currents of the motor. When arm  $A$  touches stud No. 2, then due to diminution of circuit resistance, the current again jumps up to its previous value  $I_1$ . Since speed had no time to change, the back e.m.f. remains the same as initially.

$$\therefore I_1 = \frac{V - E_{b1}}{R_2} \quad \dots(ii)$$

From (i) and (ii), we get  $\frac{I_1}{I_2} = \frac{R_1}{R_2} \quad \dots(iii)$

When arm  $A$  is held on stud No. 2 for some time, then speed and hence the back e.m.f. increases to a value  $E_{b2}$ , thereby decreasing the current to previous value  $I_2$ , so that

$$I_2 = \frac{V - E_{b2}}{R_2} \quad \dots(iv)$$

Similarly, on first making contact with stud No. 3, the current is

$$I_1 = \frac{V - E_{b2}}{R_3} \quad \dots(v)$$

From (iv) and (v), we again get  $\frac{I_1}{I_2} = \frac{R_2}{R_3} \quad \dots(vi)$

When arm  $A$  is held on stud No. 3 for some time, the speed and hence back e.m.f. increases to a new value  $E_{b3}$ , thereby decreasing the armature current to a value  $I_2$  such that

$$I_2 = \frac{V - E_{b3}}{R_3} \quad \dots(vii)$$

On making contact with stud No. 4, current jumps to  $I_1$  given by

$$I_1 = \frac{V - E_{b3}}{R_a} \quad \dots(viii)$$

From (vii) and (viii), we get  $\frac{I_1}{I_2} = \frac{R_3}{R_a} \quad \dots(ix)$

From (iii), (vi) and (ix), it is seen that

$$\frac{I_1}{I_2} = \frac{R_1}{R_2} = \frac{R_2}{R_3} = \frac{R_3}{R_a} = K \text{ (say)} \quad \dots(x)$$

Obviously,

$$R_3 = KR_a; \quad R_2 = KR_3 = K^2R_a$$

$$R_1 = KR_2 = K.K^2R_a = K^3R_a$$

In general, if  $n$  is the number of live studs and therefore  $(n - 1)$  the number of sections in the starter resistance, then

$$R_1 = K^{n-1}.R_a \text{ or } \frac{R_1}{R_a} = K^{n-1} \text{ or } \left(\frac{I_1}{I_2}\right)^{n-1} = \frac{R_1}{R_a} \quad \dots\text{from (x)}$$

Other variations of the above formula are

$$(a) \quad K^{n-1} = \frac{R_1}{R_a} = \frac{V}{I_1 R_a} = \frac{V}{I_{max} R_a}$$

$$(b) \quad K^n = \frac{V}{I_1 R_a} \cdot \frac{I_1}{I_2} = \frac{V}{I_2 R_a} = \frac{V}{I_{min} R_a} \text{ and}$$

$$(c) \quad n = 1 + \frac{\log(V / R_a I_{max})}{\log K} \text{ from (a) above.}$$

Since  $R_1 = V/I_1$  and  $R_a$  are usually known and  $K$  is known from the given values of maximum and minimum currents (determined by the load against which motor has to start), the value of  $n$  can be found and hence the value of different starter sections.

**When Number of Sections is Specified.**

Since  $I_1$  would be given,  $R_1$  can be found from  $R_1 = V/I_1$ .

Since  $n$  is known,  $K$  can be found from  $R_1/R_a = K^{n-1}$  and the lower current limit  $I_2$  from  $I_1/I_2 = K$ .

**Example 30.49.** A 10 b.h.p. (7.46 kW) 200-V shunt motor has full-load efficiency of 85%. The armature has a resistance of 0.25 Ω. Calculate the value of the starting resistance necessary to limit the starting current to 1.5 times the full-load current at the moment of first switching on. The shunt current may be neglected. Find also the back e.m.f. of the motor, when the current has fallen to its full-load value, assuming that the whole of the starting resistance is still in circuit.

**Solution.** Full-load motor current =  $7,460/200 \times 0.85 = 43.88$  A  
 Starting current,  $I_1 = 1.5 \times 43.88 = 65.83$  A  
 $R_1 = V/I_1 = 200/65.83 = 3.038 \Omega$ ;  $R_a = 0.25 \Omega$   
 $\therefore$  Starting resistance =  $R_1 - R_a = 3.038 - 0.25 = 2.788 \Omega$   
 Now, full-load current  $I_2 = 43.88$  A  
 Now,  $I_2 = \frac{V - E_{b1}}{R_1}$   
 $\therefore E_{b1} = V - I_2 R_1 = 200 - (43.88 \times 3.038) = 67$  V

**Example 30.50.** A 220-V shunt motor has an armature resistance of 0.5 Ω. The armature current at starting must not exceed 40 A. If the number of sections is 6, calculate the values of the resistor steps to be used in this starter. **(Elect. Machines, AMIE Sec. B, 1992)**

**Solution.** Since the number of starter sections is specified, we will use the relation.

$R_1/R_a = K^{n-1}$  or  $R_1 = R_a K^{n-1}$   
 Now,  $R_1 = 220/40 = 5.5 \Omega$ ,  $R_a = 0.4 \Omega$ ;  $n-1 = 6$ ,  $n = 7$   
 $\therefore 5.5 = 0.4 K^6$  or  $K^6 = 5.5/0.4 = 13.75$   
 $6 \log_{10} K = \log_{10} 13.75 = 1.1383$ ;  $K = 1.548$   
 Now,  $R_2 = R_1/K = 5.5/1.548 = 3.553 \Omega$   
 $R_3 = R_2/K = 3.553/1.548 = 2.295 \Omega$   
 $R_4 = 2.295/1.548 = 1.482 \Omega$   
 $R_5 = 1.482/1.548 = 0.958 \Omega$   
 $R_6 = 0.958/1.548 = 0.619 \Omega$   
 Resistance of 1st section =  $R_1 - R_2 = 5.5 - 3.553 = 1.947 \Omega$   
 ,, 2nd ,, =  $R_2 - R_3 = 3.553 - 2.295 = 1.258 \Omega$   
 ,, 3rd ,, =  $R_3 - R_4 = 2.295 - 1.482 = 0.813 \Omega$   
 ,, 4th ,, =  $R_4 - R_5 = 1.482 - 0.958 = 0.524 \Omega$

5th " =  $R_5 - R_6 = 0.958 - 0.619 = 0.339 \Omega$   
 6th " =  $R_6 - R_a = 0.619 - 0.4 = 0.219 \Omega$

**Example 30.51.** Find the value of the step resistance in a 6-stud starter for a 5 h.p. (3.73 kW), 200-V shunt motor. The maximum current in the line is limited to twice the full-load value. The total Cu loss is 50% of the total loss. The normal field current is 0.6 A and the full-load efficiency is found to be 88%. (D.C. Machines, Jadavpur Univ. 1988)

**Solution.** Output = 3,730 W  
 Total loss = 4,238 - 3,730 = 508 W  
 Armature Cu loss alone = 508/2 = 254 W  
 Input current = 4,238/200 = 21.19 A  
 Armature current = 21.19 - 0.6 = 20.59 A  
 $\therefore 20.59^2 R_a = 254 \quad \therefore R_a = 254/20.59^2 = 0.5989 \Omega$   
 Permissible input current = 21.19  $\times$  2 = 42.38 A  
 Permissible armature current = 42.38 - 0.6 = 41.78 A  
 $\therefore R_1 = 200/41.78 = 4.787 \Omega; n = 6; n - 1 = 5$   
 $\therefore 4.787 = K^5 \times 0.5989 \quad \therefore K^5 = 4.787/0.5989 = 7.993$   
 or  $5 \log K = \log 7.993 = 0.9027$   
 $\therefore \log K = 0.1805; K = 1.516$   
 Now  $R_2 = R_1/K = 4.789/1.516 = 3.159 \Omega$   
 $R_3 = 2.084 \Omega; R_4 = 1.376 \Omega; R_5 = 0.908 \Omega$   
 Resistance in 1st step =  $R_1 - R_2 = 4.787 - 3.159 = 1.628 \Omega$   
 Resistance in 2nd step =  $R_2 - R_3 = 3.159 - 2.084 = 1.075 \Omega$   
 Resistance in 3rd step =  $R_3 - R_4 = 2.084 - 1.376 = 0.708 \Omega$   
 Resistance in 4th step =  $R_4 - R_5 = 1.376 - 0.908 = 0.468 \Omega$   
 Resistance in 5th step =  $R_5 - R_a = 0.908 - 0.5989 = 0.309 \Omega$

The various sections are shown in Fig. 28.47.

Fig. 30.47

**Example 30.52.** Design the resistance sections of a seven-stud starter for 36.775 kW, 400V, d.c. shunt motor. Full-load efficiency is 92%, total Cu losses are 5% of the input. Shunt field resistance is 200 Ω. The lower limit of the current through the armature is to be full-load value.

(Elec. Machines, Gujarat Univ. 1987)

**Solution.** Output = 36,775 W ; Input = 36,775/0.92 = 39,980 W  
 Total Cu loss = 0.05  $\times$  39,980 = 1,999 W  
 Shunt Cu loss =  $V^2/R_{sh} = 400^2/200 = 800 \text{ W}$

Armature Cu loss = 1,999 – 800 = 1199 W

F.L. input current = 39,980/400 = 99.95 A

$I_{sh} = 400/200 = 2A ; I_a = 99.95 - 2 = 97.95 A$

$\therefore 97.95^2 R_a = 1199 W \text{ or } R_a = 0.125 \Omega$

Now, minimum armature current equals full-load current i.e.  $I_a = 97.95 A$ . As seen from Art. 30.25 in its formula given in (b), we have

$K^n = \frac{z}{\tau \cdot \tau}$

or  $K^7 = 400/97.95 \times 0.125 = 32.68$

$\therefore K = 32.68^{1/7} = 1.645$

$I_1 = \text{maximum permissible armature current}$

$= KI_2 = 1.645 \times 97.94 = 161 A$

$\therefore R_1 = V/I_1 = 400/161 = 2.483 \Omega$

$R_2 = R_1/K = 2.483/1.645 = 1.51 \Omega$

$R_3 = 1.51/1.645 = 0.917 \Omega$

$R_4 = 0.917/1.645 = 0.557 \Omega$

$R_5 = 0.557/1.645 = 0.339 \Omega$

$R_6 = 0.339/1.645 = 0.206 \Omega$

$R_7 = 0.206/1.645 = 0.125 \Omega$

Resistance in 1st step =  $R_1 - R_2 = 0.973 \Omega$

Resistance in 2nd step =  $R_2 - R_3 = 0.593 \Omega$

Resistance in 3rd step =  $R_3 - R_4 = 0.36 \Omega$

Resistance in 4th step =  $R_4 - R_5 = 0.218 \Omega$

Resistance in 5th step =  $R_5 - R_6 = 0.133 \Omega$

Resistance in 6th step =  $R_6 - R_a = 0.081 \Omega$

The various starter sections are shown in Fig 30.48.

Fig. 30.48

**Example 30.53.** Calculate the resistance steps for the starter of a 250-V, d.c. shunt motor having an armature resistance of 0.125 Ω and a full-load current of 150 A. The motor is to start against full-load and maximum current is not to exceed 200 A

(Elect.Engineering-I, Bombay Univ. 1989)

**Solution.** As the motor is to start against its full-load, the minimum current is its F.L. current i.e. 150A. We will use the formula given in Art. 30.25.

$(I_1/I_2^{n-1}) = R_1 / R_a$

Here  $I_1 = 200 A ; I_2 = 150 A ; R_1 = 250/200 = 1.25 \Omega$

$R_a = 0.125 \Omega ; n = \text{No. of live studs}$

$\therefore (200/150)^{n-1} = 1.25/0.125 = 10 \text{ or } (4/3)^{n-1} = 10$

$(n - 1) \log 4/3 = \log 10 \text{ or } (n - 1) \times 0.1249 = 1$

$\therefore (n - 1) = 1/0.1249 = 8$

Hence, there are 9 studs and 8 steps.

Now  $R_2 = R_1 \times I_2/I_1 = 1.25 \times 3/4 = 0.938 \Omega$

$R_3 = 0.938 \times 3/4 = 0.703 \Omega$

$R_4 = 0.703 \times 3/4 = 0.527 \Omega$

$$\begin{aligned}
 R_5 &= 0.527 \times 3/4 = 0.395 \, \Omega \\
 R_6 &= 0.395 \times 3/4 = 0.296 \, \Omega \\
 R_7 &= 0.296 \times 3/4 = 0.222 \, \Omega \\
 R_8 &= 0.222 \times 3/4 = 0.167 \, \Omega \\
 R_a &= 0.167 \times 3/4 = 0.125 \, \Omega \\
 \therefore \quad \text{Resistance of 1st element} &= 1.25 - 0.938 = \mathbf{0.312 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{2nd} \quad \quad \quad \text{,,} &= 0.938 - 0.703 = \mathbf{0.235 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{3rd} \quad \quad \quad \text{,,} &= 0.703 - 0.527 = \mathbf{0.176 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{4th} \quad \quad \quad \text{,,} &= 0.527 - 0.395 = \mathbf{0.132 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{5th} \quad \quad \quad \text{,,} &= 0.395 - 0.296 = \mathbf{0.099 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{6th} \quad \quad \quad \text{,,} &= 0.296 - 0.222 = \mathbf{0.074 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{7th} \quad \quad \quad \text{,,} &= 0.222 - 0.167 = \mathbf{0.055 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{8th} \quad \quad \quad \text{,,} &= 0.167 - 0.125 = \mathbf{0.042 \, \Omega}
 \end{aligned}$$

**Example 30.54.** The 4-pole, lap-wound armature winding of a 500-V, d.c. shunt motor is housed in a total number of 60 slots each slot containing 20 conductors. The armature resistance is 1.31  $\Omega$ . If during the period of starting, the minimum torque is required to be 218 N-m and the maximum torque 1.5 times the minimum torque, find out how many sections the starter should have and calculate the resistances of these sections. Take the useful flux per pole to be 23 mWb.

(Elect. Machinery-II, Bangalore Univ. 1991)

**Solution.** From the given minimum torque, we will be able to find the minimum current required during starting. Now

$$\begin{aligned}
 T_a &= 0.159 \, \Phi \, Z I_a (P/A) \\
 \therefore \quad 218 &= 0.159 \times 23 \times 10^{-3} \times (60 \times 20) I_a \times (4/4) \quad \therefore I_a = 50 \text{ A (approx.)} \\
 \text{Maximum current} &= 50 \times 1.5 = 75 \text{ A} \\
 \therefore \quad I_1 &= 75 \text{ A} ; I_2 = 50 \text{ A} \quad \therefore I_1/I_2 = 75/50 = 1.5 \\
 R_1 &= 500/75 = 6.667 \, \Omega
 \end{aligned}$$

If  $n$  is the number of stator studs, then

$$\begin{aligned}
 (I_1/I_2)^{n-1} &= R_1/R_a \quad \text{or} \quad 1.5^{n-1} = 6.667/1.31 = 5.09 \\
 \therefore (n-1) \log_{10} 1.5 &= \log_{10} 5.09 \quad \therefore (n-1) \times 0.1761 = 0.7067 \quad \therefore (n-1) = 4 \text{ or } n = 5
 \end{aligned}$$

Hence, there are five studs and four sections.

$$\begin{aligned}
 R_2 &= R_1 \times I_2/I_1 = 6.667 \times 2/3 = 4.44 \, \Omega \\
 R_3 &= 4.44 \times 2/3 = 2.96 \, \Omega ; \quad R_4 = 2.96 \times 2/3 = 1.98 \, \Omega \\
 \text{Resistance of 1st section} &= R_1 - R_2 = 6.67 - 4.44 = \mathbf{2.23 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{2nd} \quad \quad \quad \text{,,} &= R_2 - R_3 = 4.44 - 2.96 = \mathbf{1.48 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{3rd} \quad \quad \quad \text{,,} &= R_3 - R_4 = 2.96 - 1.98 = \mathbf{0.98 \, \Omega} \\
 \quad \quad \quad \text{,,} \quad \quad \quad \text{4th} \quad \quad \quad \text{,,} &= R_4 - R_a = 1.98 - 1.31 = \mathbf{0.67 \, \Omega}
 \end{aligned}$$

### 30.26. Series Motor Starters

The basic principle employed in the design of a starter for series motor is the same as for a shunt motor *i.e.*, the motor current is not allowed to exceed a certain upper limit as the starter arm moves from one stud to another. However, there is one significant difference. In the case of a series motor, the flux does not remain constant but varies with the current because armature current is also the exciting current. The determination of the number of steps is rather complicated as illustrated in Example 30.55. It may however, be noted that the section resistances form a geometrical progression.

The face-plate type of starter formerly used for d.c. series motor has been almost entirely replaced by automatic starter in which the resistance steps are cut out automatically by means of a contactor operated by electromagnets. Such starters are well-suited for remote control.

However, for winch and crane motors where frequent starting, stopping, reversing and speed variations are necessary, drum type controllers are used. They are called controllers because they can be left in the circuit for any length of time. In addition to serving their normal function of starters, they also used as speed controllers.

**Example 30.55.** (a) Show that, in general, individual resistances between the studs for a rheostat starter for a series d.c. motor with constant ratio of maximum to minimum current at starting, are in geometrical progression, stating any assumptions made.

(b) Assuming that for a certain d.c. series motor the flux per pole is proportional to the starting current, calculate the resistance of the each rheostat section in the case of a 50 b.h.p. (37.3 kW) 440-V motor with six sections.

The total armature and field voltage drop at full-load is 2% of the applied voltage, the full-load efficiency is 95% and the maximum starting current is 130% of full-load current.

**Solution.** (a) Let  $I_1$  = maximum current,  $I_2$  = minimum current  
 $\Phi_1$  = flux/pole for  $I_1$ ;  $\Phi_2$  = flux/pole for  $I_2$   
 $\frac{I_1}{I_2} = K$  and  $\frac{\Phi_1}{\Phi_2} = \alpha$ .

Let us now consider the conditions when the starter arm is on the  $n$ th and  $(n + 1)$ th stud. When the current is  $I_2$ , then  $E_b = V - I_2 R_n$ .

If, now, the starter is moved up to the  $(n + 1)$ th stud, then

$$E_b' = \frac{\Phi_1}{\Phi_2} \cdot E_b = \alpha E_b$$

$$\therefore R_{n+1} = \frac{z - r'_{a1}}{c_1} = \frac{z - \alpha r_{a2}}{c_1} = \frac{z - \alpha (z - r_{a2})}{c_1} = \frac{z}{c_1} (1 - \alpha) + \alpha \frac{r_{a2}}{c_1}$$

Now,  $V/I_1 = R_1$ —the total resistance in the circuit when the starter arm is on the first stud.

$$\therefore R_{n+1} = R_1 (1 - \alpha) + \frac{\alpha}{K} R_n$$

Similarly, by substituting  $(n - 1)$  for  $n$ , we get  $R_n = R_1 (1 - \alpha) + \frac{\alpha}{K} R_{n-1}$

Therefore, the resistance between the  $n$ th and  $(n + 1)$ th studs is

$$r_n = R_n - R_{n+1} = \frac{\alpha}{K} R_{n-1} - \frac{\alpha}{K} R_n = \frac{\alpha}{K} (R_{n-1} - R_n) = \frac{\alpha}{K} r_{n-1}$$

$$\therefore \frac{r_n}{r_{n-1}} = \frac{\alpha}{K} = \frac{\Phi_1}{\Phi_2} \times \frac{I_2}{I_1} = b \quad \text{— constant}$$

Obviously, the resistance elements form a geometrical progression series.

(b) Full-load input current =  $\frac{37,300}{440 \times 0.95} = 89.2$  A

Max. starting current  $I_1 = 1.3 \times 89.2 = 116$  A

Arm. and field voltage drop on full-load = 2% of 440 =  $0.02 \times 440 = 8.8$  V

Resistance of motor =  $8.8/89.2 = 0.0896 \Omega$

Total circuit resistance on starting,  $R_1 = V/I_1 = 440/116 = 3.79 \Omega$

Assuming straight line magnetisation, we have  $I_1 \propto \Phi_1$  and  $I_2 \propto \Phi_2$

$$\therefore I_1/I_2 = \Phi_1/\Phi_2 \quad \therefore \alpha = K \text{ and } b = \alpha/K = 1 \quad \therefore r_n = b \times r_{n-1}$$

In other words, all sections have the same resistance.

$$\therefore r = \frac{R_1 - R_{motor}}{\text{No. of sections}} = \frac{3.79 - 0.0896}{6} = 0.6176 \Omega$$

**Example 30.56.** A 75 h.p. (55.95 kW) 650-V, d.c. series traction motor has a total resistance of 0.51 Ω. The starting current is to be allowed to fluctuate between 140 A and 100 A the flux at 140 A being 20 % greater than at 100 A. Determine the number of steps required in the controller and the resistance of each step.

**Solution.** Let  $R_1$  = total resistance on the first stud = 650/140 = 4.65 Ω

When motor speeds up, then back e.m.f. is produced and current falls to  $I_2$ .

$$V = E_{b1} + I_2 R_1 \quad \dots(i)$$

When the starter moves to the next stud, the speed is still the same, but since current rises to  $I_1$  for which flux is 1.2 times greater than for  $I_2$ , hence back e.m.f. becomes  $1.2 E_{b1}$ . Since resistance in the circuit is now  $R_2$ .

$$\therefore V = I_1 R_2 + 1.2 E_{b1} \quad \dots(ii)$$

From (i) and (ii) we get,  $0.2 V = 1.2 I_2 R_1 - I_1 R_2$

$$\therefore R_2 = (1.2 I_2 / I_1) R_1 - 0.2 V / I_1 = (1.2 I_2 / I_1) R_1 - 0.2 R_1 = (1.2 I_2 / I_1 - 0.2) R_1$$

$$\text{Similarly } R_3 = (1.2 I_2 / I_1) R_2 - 0.2 R_1$$

In this way, we continue till we reach the value of resistance equal to the armature resistance. Hence, we obtain  $R_1, R_2$  etc. and also the number of steps.

In the present case,  $I_1 = 140$  A,  $I_2 = 100$  A,  $V = 650$  V and  $I_1/I_2 = 100/140 = 1.14$

$$\therefore R_1 = 4.65 \Omega; R_2 = (1.2/1.4 - 0.2) 4.65 = 3.07 \Omega$$

$$R_3 = (1.2/1.4) \times 3.07 - 0.2 \times 4.65 = 1.70 \Omega$$

$$R_4 = (1.2/1.4) \times 1.7 - 0.2 \times 4.65 = 0.53 \Omega$$

We will stop here because  $R_4$  is very near the value of the motor resistance. Hence, there are 4 studs and 3 sections or steps.

$$R_1 - R_2 = 4.65 - 3.07 = 1.58 \Omega, R_2 - R_3 = 3.07 - 1.7 = 1.37 \Omega$$

$$R_3 - R_4 = 1.70 - 0.53 = 1.17 \Omega$$

**Note.** It will be seen that

$$R_2 - R_3 = (1.2 I_2 / I_1) (R_1 - R_2) \text{ and } R_3 - R_4 = (1.2 I_2 / I_1) (R_2 - R_3) \text{ and so on.}$$

or 
$$\frac{R_2 - R_3}{R_1 - R_2} = \frac{R_3 - R_4}{R_2 - R_3} = 1.2 \frac{I_2}{I_1} = \frac{\Phi_1}{\Phi_2} \times \frac{I_2}{I_1} = \frac{\alpha}{K} = b$$

It is seen that individual resistances of various sections decrease in the ratio of  $\alpha/K = b$ .

### 30.27. Thyristor Controller Starters

The moving parts and metal contacts etc., of the resistance starters discussed in Art. 30.21 can be eliminated by using thyristors which can short circuit the resistance sections one after another. A thyristor can be switched on to the conducting state by applying a suitable signal to its gate terminal. While conducting, it offers zero resistance in the forward (i.e., anode-to-cathode) direction and thus acts as a short-circuit for the starter resistance section across which it is connected. It can be switched off (i.e., brought back to the non-conducting state) by reversing the polarity of its anode-cathode voltage. A typical thyristor-controlled starter for d.c. motors is shown in Fig. 30.49.

After switching on the main supply, when switch  $S_1$  is pressed, positive signal is applied to gate G of thyristor  $T_1$  which is, therefore, turned ON. At the same time, shunt field gets established since it is directly connected across the d.c. supply. Consequently, motor armature current  $I_a$  flows via  $T_1$ ,

$R_2$ ,  $R_3$  and  $R_4$  because  $T_2$ ,  $T_3$  and  $T_4$  are, as yet in the non-conducting state. From now onwards, the starting procedure is automatic as detailed below :

1. As  $S_1$  is closed, capacitor  $C$  starts charging up with the polarity as shown when  $I_a$  starts flowing.
2. The armature current and field flux together produce torque which accelerates the motor and load.

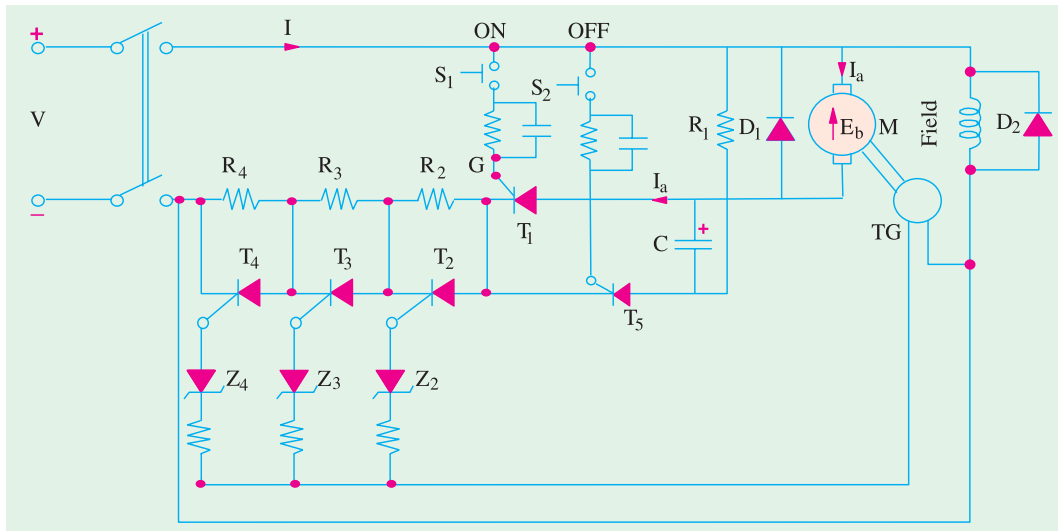

Fig. 30.49

3. As motor speeds up, voltage provided by tachogenerator ( $TG$ ) is proportionately increased because it is coupled to the motor.
4. At some motor speed, the voltage provided by  $TG$  becomes large enough to breakdown Zener diode  $Z_2$  and hence trigger  $T_2$  into conduction. Consequently,  $R_2$  is shorted out and now  $I_a$  flows via motor armature,  $T_1$ ,  $T_2$ ,  $R_3$  and  $R_4$  and back to the negative supply terminal.
5. As  $R_2$  is cut out,  $I_a$  increases, armature torque increases, motor speed increases which further increases the voltage output of the tachogenerator. At some speed,  $Z_3$  breaks down, thereby triggering  $T_3$  into conduction which cuts out  $R_3$ .
6. After sometime,  $R_4$  is cut out as  $Z_4$  breaks down and triggers  $T_4$  into conduction. In fact, Zener diodes  $Z_2$ ,  $Z_3$  and  $Z_4$  can be rated for  $1/3$ ,  $1/2$  and  $3/4$  full speed respectively.

For stopping the motor, switch  $S_2$  is closed which triggers  $T_5$  into conduction, thereby establishing current flow via  $R_1$ . Consequently, capacitor  $C$  starts discharging thereby reverse-biasing  $T_1$  which stops conducting. Hence  $I_a$  ceases and, at the same time,  $T_2$ ,  $T_3$  and  $T_4$  also revert back to their non-conducting state.

Incidentally, it may be noted that the function of  $C$  is to switch  $T_1$ , ON and OFF. Hence, it is usually called **commutating capacitor**.

The function of the diodes  $D_1$  and  $D_2$  is to allow the decay of inductive energy stored in the motor armature and field when supply is disconnected. Supply failure will cause the thyristors to block because of this current decay, thereby providing protection usually given by no-voltage release coil.

Recently, thyristor starting circuits have been introduced which use no starting resistance at all, thereby making the entire system quite efficient and optimized as regards starting time. These are based on the principle of 'voltage chopping' (Art. 30.12). By varying the chopping frequency, the ratio of the time the voltage is ON to the time it is OFF can be varied. By varying this ratio, the average voltage applied to the motor can be changed. A low average voltage is needed to limit the

armature current while the motor is being started and gradually the ratio is increased to reach the maximum at the rated speed of the motor.

### Tutorial Problems 32.2

1. A shunt-wound motor runs at 600 r.p.m. from a 230-V supply when taking a line current of 50 A. Its armature and field resistances are  $0.4 \Omega$  and  $104.5 \Omega$  respectively. Neglecting the effects of armature reaction and allowing 2 V brush drop, calculate (a) the no-load speed if the no-load line current is 5A (b) the resistance to be placed in armature circuit in order to reduce the speed to 500 r.p.m. when motor is taking a line current of 50 A (c) the percentage reduction in the flux per pole in order that the speed may be 750 r.p.m. when the armature current is 30 A with no added resistance in the armature circuit. [(a) 652 r.p.m. (b)  $0.73 \Omega$  (c) 1.73 %]
2. The resistance of the armature of a 250-V shunt motor is  $0.3 \Omega$  and its full-load speed is 1000 r.p.m. Calculate the resistance to be inserted in series with the armature to reduce the speed with full-load torque to 800 r.p.m., the full-load armature current being 5A. If the load torque is then halved, at what speed will the motor run? Neglect armature reaction. [ $0.94 \Omega$ ; 932 r.p.m.]
3. A 230-V d.c. shunt motor takes an armature current of 20 A on a certain load. Resistance of the armature is  $0.5 \Omega$ . Find the resistance required in series with the armature to half the speed if (a) the load torque is constant (b) the load torque is proportional to the square of the speed. [(a)  $5.5 \Omega$  (b)  $23.5 \Omega$ ]
4. A 230-V series motor runs at 1200 r.p.m. at a quarter full-load torque, taking a current of 16 A. Calculate its speed at half and full-load torques. The resistance of the armature brushes, and field coils is  $0.25 \Omega$ . Assume the flux per pole to be proportional to the current. Plot torque/speed graph between full and quarter-load. [842 r.p.m. ; 589 r.p.m.]
5. A d.c. series motor drives a load the torque of which is proportional to the square of the speed. The motor current is 20 A when speed is 500 r.p.m. Calculate the speed and current when the motor field winding is shunted by a resistance of the same value as the field winding. Neglect all motor losses and assume that the magnetic field is unsaturated. [595 r.p.m. ; 33.64 A]  
(Electrical Machines-I, Aligarh Muslim Univ. 1979)
6. A d.c. series motor, with unsaturated magnetic circuit and with negligible resistance, when running at a certain speed on a given load takes 50 A at 500 V. If the load torque varies as the cube of the speed, find the resistance which should be connected in series with machine to reduce the speed by 25 per cent. [7.89  $\Omega$ ]  
(Electrical Engg-I, M.S. Univ. Baroda 1980)
7. A series motor runs at 500 r.p.m. on a certain load. Calculate the resistance of a diverter required to raise the speed to 650 r.p.m. with the same load current, given that the series field resistance is  $0.05 \Omega$  and the field is unsaturated. Assume the ohmic drop in the field and armature to be negligible. [0.1665  $\Omega$ ]
8. A 230-V d.c. series motor has armature and field resistances of  $0.5 \Omega$  and  $0.3 \Omega$  respectively. The motor draws a line current of 40 A while running at 400 r.p.m. If a diverter of resistance  $0.15 \Omega$  is used, find the new speed of the motor for the same armature current.  
It may be assumed that flux per pole is directly proportional to the field current. [1204 r.p.m.]  
(Electrical Engineering Grad. I.E.T.E. June 1986)
9. A 250-V, d.c. shunt motor runs at 700 r.p.m. on no-load with no extra resistance in the field and armature circuit. Determine :
  - (i) the resistance to be placed in series with the armature for a speed of 400 r.p.m. when taking a total current of 16 A.
  - (ii) the resistance to be placed in series with the field to produce a speed of 1,000 r.p.m. when taking an armature current of 18 A.

Assume that the useful flux is proportional to the field. Armature resistance =  $0.35 \Omega$ , field resistance =  $125 \Omega$ . [(i)  $7.3 \Omega$  (ii)  $113 \Omega$ ] (Elect. Engg. Grad. I.E.T.E., June 1984)

10. A d.c. series motor is operating from a 220-V supply. It takes 50 A and runs at 1000 r.p.m. The resistance of the motor is  $0.1 \Omega$ . If a resistance of  $2 \Omega$  is placed in series with the motor, calculate the resultant speed if the load torque is constant. [534 r.p.m.]
11. A d.c. shunt motor takes 25 A when running at 1000 r.p.m. from a 220-V supply. Calculate the current taken from the supply and the speed if the load torque is halved, a resistance of  $5 \Omega$  is placed in the armature circuit and a resistance of  $50 \Omega$  is placed in the field circuit. Armature resistance =  $0.1 \Omega$ ; field resistance =  $100 \Omega$ . Assume that the field flux per pole is directly proportional to the field current. [17.1 A; 915 r.p.m.] (Elect. Technology, Gwalior Univ. Nov. 1977)
12. A 440-V shunt motor takes an armature current of 50 A and has a flux/pole of 50 mWb. If the flux is suddenly decreased to 45 mWb, calculate (a) instantaneous increase in armature current (b) percentage increase in the motor torque due to increase in current (c) value of steady current which motor will take eventually (d) the final percentage increase in motor speed. Neglect brush contact drop and armature reaction and assume an armature resistance of  $0.6 \Omega$ . [(a)  $118 \text{ A}$  (b)  $112 \%$  (c)  $5.55 \text{ A}$  (d)  $10\%$ ]
13. A 440-V shunt motor while running at 1500 r.p.m. takes an armature current of 30 A and delivers a mechanical output of 15 h.p. (11.19 kW). The load torque varies as the square of the speed. Calculate the value of resistance to be connected in series with the armature for reducing the motor speed to 1300 r.p.m. and the armature current at that speed. [2.97  $\Omega$ , 22.5 A]
14. A 460-V series motor has a resistance of  $0.4 \Omega$  and takes a current of 25 A when there is no additional controller resistance in the armature circuit. Its speed is 1000 r.p.m. The control resistance is so adjusted as to reduce the field flux by 5%. Calculate the new current drawn by the motor and its speed. Assume that the load torque varies as the square of the speed and the same motor efficiency under the two conditions of operation. [22.6 A; 926 r.p.m.] (Elect. Machines, South Gujarat Univ. Oct. 1977)
15. A 460-V, series motor runs at 500 r.p.m. taking a current of 40 A. Calculate the speed and percentage change and torque if the load is reduced so that the motor is taking 30 A. Total resistance of armature and field circuit is  $0.8 \Omega$ . Assume flux proportional to the field current. [680 r.p.m. 43.75%]
16. A 440-V, 25 h.p (18.65 kW) motor has an armature resistance of  $1.2 \Omega$  and full-load efficiency of 85%. Calculate the number and value of resistance elements of a starter for the motor if maximum permissible current is 1.5 times the full-load current. [1.92  $\Omega$ , 1.30  $\Omega$ , 0.86  $\Omega$ ; 0.59  $\Omega$ ] (Similar example in JNTU, Hyderabad, 2000)
17. A 230-V, d.c. shunt motor has an armature resistance of  $0.3 \Omega$ . Calculate (a) the resistance to be connected in series with the armature to limit the armature current to 75 A at starting and (b) value of the generated e.m.f. when the armature current has fallen to 50 A with this value of resistance still in circuit. [(a)  $2.767 \Omega$  (b)  $76.7 \text{ A}$ ]
18. A 200-V, d.c. shunt motor takes full-load current of 12 A. The armature circuit resistance is  $0.3 \Omega$  and the field circuit resistance is  $100 \Omega$ . Calculate the value of 5 steps in the 6-stud starter for the motor. The maximum starting current is not to exceed 1.5 times the full-load current. [6.57  $\Omega$ , 3.12  $\Omega$ , 1.48  $\Omega$ , 0.7  $\Omega$ , 0.33  $\Omega$ ]
19. The resistance of a starter for a 200-V, shunt motor is such that maximum starting current is 30 A. When the current has decreased to 24 A, the starter arm is moved from the first to the second stud. Calculate the resistance between these two studs if the maximum current in the second stud is 34 A. The armature resistance of the motor is  $0.4 \Omega$ . [1.334  $\Omega$ ]
20. A totally-enclosed motor has thermal time constant of 2 hr. and final temperature rise at no-load and  $40^\circ$  on full load.

Determine the limits between which the temperature fluctuates when the motor operates on a load cycle consisting of alternate period of 1 hr. on full-load and 1 hr. on no-load, steady state conditions having been established. [28.7° C, 21.3° C]

21. A motor with a thermal time constant of 45 min. has a final temperature rise of 75°C on continuous rating (a) What is the temperature rise after one hour at this load ? (b) If the temperature rise on one-hour rating is 75°C, find the maximum steady temperature at this rating (c) When working at its one-hour rating, how long does it take the temperature to increase from 60°C to 75°C ? [(a) 55 °C (b) 102 °C (c) 20 min]

(Electrical Technology, M.S. Univ. Baroda. 1976)

### OBJECTIVE TESTS – 30

- The speed of a d.c. motor can be controlled by varying
  - its flux per pole
  - resistance of armature circuit
  - applied voltage
  - all of the above
- The most efficient method of increasing the speed of a 3.75 kW d.c. shunt motor would be the .....method.
  - armature control
  - flux control
  - Ward-Leonard
  - tapped-field control
- Regarding Ward-Leonard system of speed control which statement is **false** ?
  - It is usually used where wide and very sensitive speed control is required.
  - It is used for motors having ratings from 750 kW to 4000 kW
  - Capital outlay involved in the system is right since it uses two extra machines.
  - It gives a speed range of 10 : 1 but in one direction only.
  - It has low overall efficiency especially at light loads.
- In the rheostatic method of speed control for a d.c. shunt motor, use of armature diverter makes the method
  - less wasteful
  - less expensive
  - unsuitable for changing loads
  - suitable for rapidly changing loads
- The chief advantage of Ward-Leonard system of d.c. motor speed control is that it
  - can be used even for small motors
  - has high overall efficiency at all speeds
  - gives smooth, sensitive and wide speed control
  - uses a flywheel to reduce fluctuations in power demand
- The flux control method using paralleling of field coils when applied to a 4-pole series d.c. motor can give ..... speeds.
  - 2
  - 3
  - 4
  - 6
- The series-parallel system of speed control of series motors widely used in traction work gives a speed range of about
  - 1 : 2
  - 1 : 3
  - 1 : 4
  - 1 : 6
- In practice, regenerative braking is used when
  - quick motor reversal is desired
  - load has overhauling characteristics
  - controlling elevators, rolling mills and printing presses etc.
  - other methods can not be used.
- Statement 1.** A direct-on-line (DOL) starter is used to start a small d.c. motor because **Statement 2.** it limits initial current drawn by the armature circuit.
  - both statement 1 and 2 are incorrect
  - both statement 1 and 2 are correct
  - statement 1 is correct but 2 is wrong
  - statement 2 is correct but 1 is wrong
- Ward-Leonard system of speed control is **NOT** recommended for
  - wide speed range
  - constant-speed operation
  - frequent motor reversals
  - very low speeds
- Thyristor chopper circuits are employed for
  - lowering the level of a d.c. voltage
  - rectifying the a.c. voltage
  - frequency conversion
  - providing commutation circuitry

- 12.** An inverter circuit is employed to convert  
 (a) a.c. voltage into d.c. voltage  
 (b) d.c. voltage into a.c. voltage  
 (c) high frequency into low frequency  
 (d) low frequency into high frequency
- 13.** The phase-control rectifiers used for speed of d.c. motors convert fixed a.c. supply voltage into  
 (a) variable d.c. supply voltage  
 (b) variable a.c. supply voltage  
 (c) full-rectified a.c. voltage  
 (d) half-rectified a.c. voltage
- 14.** If some of the switching devices in a convertor are controlled devices and some are diodes, the convertor is called  
 (a) full convertor    (b) semiconvertor  
 (c) solid-state chopper  
 (d) d.c. convertor
- 15.** A solid-state chopper converts a fixed-voltage d.c. supply into a  
 (a) variable-voltage a.c. supply  
 (b) variable-voltage d.c. supply  
 (c) higher-voltage d.c. supply  
 (d) lower-voltage a.c. supply
- 16.** The d.c. motor terminal voltage supplied by a solid-state chopper for speed control purposes varies.....with the duty ratio of the chopper  
 (a) inversely      (b) indirectly  
 (c) linearly      (d) parabolically

**ANSWERS**

- 1. d    2. b    3. d    4. d    5. c    6. b    7. c    8. b    9. c    10. b    11. a**  
**12. b    13. a    14. b    15. b    16. c**

# CHAPTER 31

## Learning Objectives

- Brake Test
- Swinburne's Test
- Advantages of Swinburne's Test
- Main Disadvantages
- Regenerative or Hopkinson's Test
- Alternative Connections for Hopkinson's Test
- Merits of Hopkinson's Test
- Retardation or Running Down Test
- Field's Test for Series Motors
- Objective Test
- Questions and Answers on D.C. Motors.

## TESTING OF D.C. MACHINES

Testing is performed on D.C. machines to determine efficiency and power losses

### 31.1 Brake Test

It is a direct method and consists of applying a brake to a water-cooled pulley mounted on the motor shaft as shown in Fig. 31.1. The brake band is fixed with the help of wooden blocks gripping the pulley. One end of the band is fixed to earth via a spring balance  $S$  and the other is connected to a suspended weight  $W_1$ . The motor is running and the load on the motor is adjusted till it carries its full load current.

Let  $W_1$  = suspended weight in kg  
 $W_2$  = reading on spring balance in kg-wt

The net pull on the band due to friction at the pulley is  $(W_1 - W_2)$  kg. wt. or  $9.81 (W_1 - W_2)$  newton.

If  $R$  = radius of the pulley in metre  
 and  $N$  = motor or pulley speed in r.p.s.

Then, shaft torque  $T_{sh}$  developed by the motor  
 $= (W_1 - W_2) R$  kg-m =  $9.81 (W_1 - W_2) R$  N-m

Motor output power =  $T_{sh} \times 2\pi N$  watt  
 $= 2\pi \times 9.81 N (W_1 - W_2) R$  watt  
 $= 61.68 N (W_1 - W_2) R$  watt

Let  $V$  = supply voltage ;  $I$  = full-load current taken by the motor.  
 Then, input power =  $VI$  watt

$$\therefore \eta = \frac{\text{Output}}{\text{Input}} = \frac{61.68 N(W_1 - W_2)R}{VI}$$

The simple brake test described above can be used for small motors only, because in the case of large motors, it is difficult to dissipate the large amount of heat generated at the brake.

Another simple method of measuring motor output is by the use of poney brake one form of which is shown in Fig. 31.2 (a). A rope is wound round the pulley and its two ends are attached to two spring balances  $S_1$  and  $S_2$ . The tension of the rope can be adjusted with the help of swivels. Obviously, the force acting tangentially on the pulley is equal to the difference between the readings of the two spring balances. If  $R$  is the pulley radius, the torque at the pulley is  $T_{sh} = (S_1 - S_2)R$ . If  $\omega (= 2\pi N)$  is the angular velocity of the pulley, then

motor output =  $T_{sh} \times \omega = 2\pi N (S_1 - S_2)R$  m-kg. wt. =  $9.81 \times 2\pi N (S_1 - S_2) R$  watt.

The motor input may be measured as shown in Fig. 31.2 (b). Efficiency may, as usual, be found by using the relation  $\eta = \text{output/input}$ .

**Example 31.1.** In a brake test the effective load on the branch pulley was 38.1 kg, the effective diameter of the pulley 63.5 cm and speed 12 r.p.s. The motor took 49 A at 220 V. Calculate the output power and the efficiency at this load.

**Solution.** Effective load  $(W_1 - W_2) = 38.1$  kg. wt ; radius =  $0.635/2 = 0.3175$  m

Shaft torque =  $38.1 \times 0.3175$  kg-m =  $9.81 \times 38.1 \times 0.3175 = 118.6$  N-m

Power output = torque  $\times$  angular velocity in rad/s =  $118.6 \times 2\pi \times 12 = 8,945$  W

Now, motor input =  $49 \times 220$  W  $\therefore$  Motor  $\eta = \frac{8,945}{49 \times 220} = 0.83$  or **83%**

Fig. 31.1

Fig. 31.2 (a)

Fig. 31.2 (b)

**Example 31.2(a).** The following readings are obtained when doing a load test on a d.c. shunt motor using a brake drum :

Spring balance reading	10 kg and 35 kg	Diameter of the drum	40 cm
Speed of the motor	950 r.p.m.	Applied voltage	200 V
Line current	30 A		

Calculate the output power and the efficiency. (Electrical Engineering, Madras Univ. 1986)

**Solution.** Force on the drum surface  $F = (35 - 10) = 25 \text{ kg wt} = 25 \times 9.8 \text{ N}$

Drum radius  $R = 20 \text{ cm} = 0.2 \text{ m}$  ; Torque  $T_{sh} = F \times R = 25 \times 9.8 \times 0.2 = 49 \text{ N}$

$N = 950/60 = 95/6 \text{ r.p.s.}$  ;  $\omega = 2\pi (95/6) = 99.5 \text{ rad/s}$

Motor output =  $T_{sh} \times \omega \text{ watt} = 49 \times 99.5 = 4,876 \text{ W}$

Motor input =  $200 \times 30 = 6000 \text{ W}$  ;  $\eta = 4876/6000 = 0.813$  or **81.3%**

**Example 31.2(b).** In a brake-test, on a d.c. shunt motor, the tensions on the two sides of the brake were 2.9 kg and 0.17 kg. Radius of the pulley was 7 cm. Input current was 2 amp at 230 volts. The motor speed was 1500 rpm. Find the torque, power-output and efficiency.

(Bharathiar Univ. April 1998)

Fig. 31.3. D.C. Shunt Motor Brake Test

**Solution.** Net force on pulley =  $2.90 - 0.17 = 2.73 \text{ kg}$   
 =  $2.73 \times 9.81 = 26.78 \text{ Nw}$

$$\begin{aligned} \text{Net torque} &= \text{Force} \times \text{Radius} = 26.78 \times 7/100 \\ &= 1.8746 \text{ Nw-m} \\ \text{Power output} &= \text{Torque} \times \text{Radians/sec.} \\ &= 1.8746 \times 2\pi \times 1500/60 \\ &= 294 \text{ watts} \\ \text{Efficiency} &= 294/(230 \times 2) = 0.639 \\ \% \text{ efficiency} &= 63.9\% \end{aligned}$$

### 31.2. Swinburne's\* Test (or No-load Test or Losses Method)

It is a simple method in which losses are measured separately and from their knowledge, efficiency at any desired load can be predetermined in advance. The only running test needed is no-load test. *However, this test is applicable to those machines in which flux is practically constant i.e. shunt and compound-wound machines.*

Shunt regulator

The machine is running as a motor on no-load at its rated voltage *i.e.* voltage stamped on the name-plate. The speed is adjusted to the rated speed with the help of shunt regulator as shown in Fig. 31.4.

The no-load current  $I_0$  is measured by the ammeter  $A_1$  whereas shunt field current  $I_{sh}$  is given by ammeter  $A_2$ . The no-load armature current is  $(I_0 - I_{sh})$  or  $I_{a0}$ .

$$\begin{aligned} \text{Let, supply voltage} &= V & \text{no-load input} &= VI_0 \text{ watt} \\ \therefore \text{Power input to armature} &= V(I_0 - I_{sh}); & \text{Power input to shunt} &= VI_{sh} \end{aligned}$$

No-load power input to armature supplies the following :

- (i) Iron losses in core
- (ii) friction loss
- (iii) windage loss and
- (iv) armature Cu loss,  $(I_0 - I_{sh})^2 R_a$  or  $I_{a0}^2 R_a$

In calculating armature Cu loss, 'hot' resistance of armature should be used. A stationary measurement of armature circuit resistance at the room-temperature of, say, 15°C is made by passing current through the armature from a low voltage d.c. supply [Fig. 31.5 (a)].

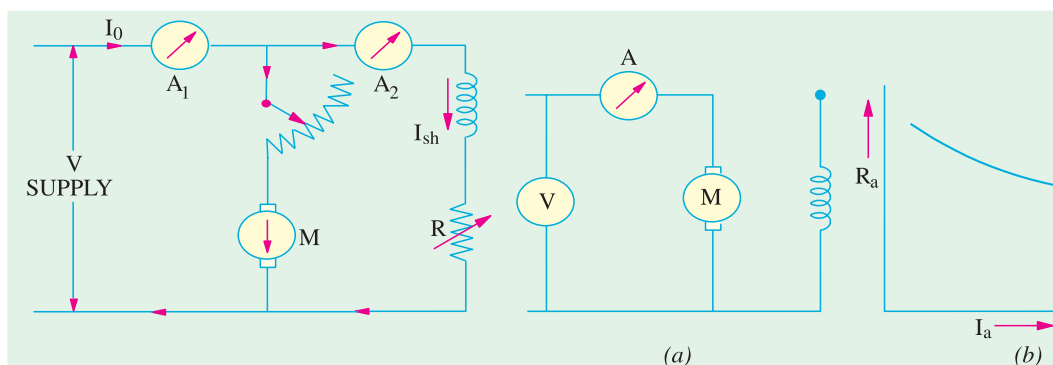

Fig. 31.4

Fig. 31.5

\* Sir James Swinburne (1858-1958) made outstanding contributions to the development of electric lamps, electric machines and synthetic resins.

Then, the 'hot' resistance, allowing a temperature rise of 50°C is found thus :

$$R_{15} = R_0(1 + 15\alpha_0) ; R_{65} = (1 + 65\alpha_0), R_{65} = R_{15} \times \frac{1 + 65\alpha_0}{1 + 15\alpha_0}$$

Taking  $\alpha_0 = 1/234.5$ , we have  $R_{65} = R_{15} \times \frac{234.5 + 65}{234.5 + 15} = 1.2 R_{15}$  (approx. \*)

If we subtract from the total input the no-load armature Cu loss, then we get constant losses.

$$\therefore \text{Constant losses} \quad W_c = VI_0 - (I_0 - I_{sh})^2 R_a$$

Knowing the constant losses of the machine, its efficiency at any other load can be determined as given below. Let  $I$  = load current at which efficiency is required.

Then, armature current is  $I_a = I - I_{sh}$  ...if machine is motoring  
 $= I + I_{sh}$  ...if machine is generating

### Efficiency when running as a motor

Input =  $VI$ , Armature Cu loss =  $I_a^2 R_a = (I - I_{sh})^2 R_a$  ...found above  
 Constant losses =  $W_c$

$$\therefore \text{Total losses} = (I - I_{sh})^2 R_a + W_c ; \eta_m = \frac{\text{input} - \text{losses}}{\text{input}} = \frac{VI - (I - I_{sh})^2 R_a - W_c}{VI}$$

### Efficiency when running as a generator

Output =  $VI$ ; Armature, Cu loss =  $(I + I_{sh})^2 R_a$ ; Constant loss =  $W_c$  ...found above

$$\therefore \text{Total losses} = (I + I_{sh})^2 R_a + W_c ; \eta_g = \frac{\text{output}}{\text{output} + \text{losses}} = \frac{VI}{VI + (I + I_{sh})^2 R_a + W_c}$$

### 31.3. Advantages of Swinburne's Test

1. It is convenient and economical because power required to test a large machine is small *i.e.* only no-load input power.
2. The efficiency can be predetermined at any load because constant-losses are known.

### 31.4. Main Disadvantages

1. No account is taken of the change in iron losses from no-load to full-load. At full-load, due to armature reaction, flux is distorted which increases the iron losses in some cases by as much as 50%.
2. As the test is on no-load, it is impossible to know whether commutation would be satisfactory at full-load and whether the temperature rise would be within the specified limits.

**Example 31.3.** A 220 V, d.c. shunt motor at no load takes a current of 2.5 A. The resistances of the armature and shunt field are 0.8 Ω and 200 Ω respectively. Estimate the efficiency of the motor when the input current is 20 A. State precisely the assumptions made.

(Electrical Technology, Kerala Univ. 1986)

**Solution.** No-load input =  $220 \times 2.5 = 550$  W

This input meets all kinds of no-load losses *i.e.* armature Cu loss and constant losses.

$I_{sh} = 220/200 = 1.1$  A. No-load arm current,  $I_{a0} = 2.5 - 1.1 = 1.4$  A

\* The armature resistance is found to decrease slightly with increasing armature current as shown in Fig. 31.5 (b). This is due to the fact that brush contact resistance is inversely proportional to the armature current.

$$\text{No-load armature Cu loss} = I_{a0}^2 R_a = 1.4^2 \times 0.8 = 1.6 \text{ W}$$

$$\text{Constant losses} = 550 - 1.6 = 548.4 \text{ W}$$

**When input current is 20 A**

$$I_a = 32 - 1.1 = 30.9 \text{ A ; Armature Cu loss} = 30.9^2 \times 0.8 = 764 \text{ W}$$

$$\text{Total loss} = 764 + 548.4 = 1312 \text{ W (approx.) ; Input} = 220 \times 20 = 4,400 \text{ W}$$

$$\text{Output} = 4,400 - 1,312 = 3,088 \text{ W ; Efficiency} = (3088/4400) \times 100 = \mathbf{70.2\%}$$

In the above calculations, it has been assumed that :

**1.** mechanical losses remain constant even through motor speed changes from no-load to the given load.

**2.** effect of armature reaction on main pole flux with a consequent change in iron losses has been neglected.

**3.** decrease in flux due to increase in shunt resistance by heating has been neglected.

**Example 31.4.** When running on no-load, a 400-V shunt motor takes 5 A. Armature resistance is 0.5  $\Omega$  and field resistance 200  $\Omega$ . Find the output of the motor and efficiency when running on full-load and taking a current of 50 A. Also, find the percentage change in speed from no-load to full-load. **(Electro Mechanics, Allahabad Univ. 1991)**

**Solution.** No-load input =  $400 \times 5 = 2,000 \text{ W}$

This input goes to meet all kinds of no-load losses *i.e.* armature Cu loss and constant losses.

$$I_{sh} = 400/200 = 2 \text{ A ; No-load } I_a = 5 - 2 = 3 \text{ A}$$

$$\text{No-load arm. Cu loss} = 3^2 \times 0.5 = 4.5 \text{ W ; Constant losses} = 2,000 - 4.5 = \mathbf{1,995.5 \text{ W}}$$

**When line current is 50 A**

$$I_a = 50 - 2 = 48 \text{ A ; Arm. Cu loss} = 48^2 \times 0.5 = 1,152 \text{ W}$$

$$\text{Total loss on F.L.} = 1,152 + 1,995.5 = 3,147.5 \text{ W ; Input} = 50 \times 400 = 20,000 \text{ W}$$

$$\text{Output} = 20,000 - 3,147.5 = \mathbf{16,852.5 \text{ W} = 16.8 \text{ kW}}$$

$$\text{F.L. efficiency} = 16,852.5/20,000 = 0.8426 \text{ or } \mathbf{84.26\%}$$

$$\text{Now, } E_{b1} = 400 - (3 \times 0.5) = 398.5 \text{ V ; } E_{b2} = 400 - (48 \times 0.5) = 376 \text{ V}$$

$$\frac{N_1}{N_2} = \frac{E_{b1}}{E_{b2}} = \frac{398.5}{376} \quad \therefore \frac{N_1 - N_2}{N_2} = \frac{22.5}{376} = 0.0598$$

$\therefore$  percentage change in speed = **5.98**

**Example 31.5.** The no-load test of a 44.76 kW, 220-V, d.c. shunt motor gave the following figures:

Input current = 13.25 A ; field current = 2.55 A ; resistance of armature at 75°C = 0.032  $\Omega$  and brush drop = 2 V. Estimate the full-load current and efficiency.

**(Electrical Engineering, Madras Univ. 1987)**

**Solution. No-load Condition**

$$\text{No-load input} = 220 \times 13.25 = 2915 \text{ W ; Armature current} = 13.25 - 2.55 = 10.7 \text{ A}$$

$$\text{Armature Cu loss} = 10.7^2 \times 0.032 = 3.6 \text{ W}$$

$$\text{Loss due to brush drop} = 2 \times 10.7 = 21.4 \text{ W}$$

$$\text{Variable loss} = 21.4 + 3.6 = 25 \text{ W}, \text{ Constant losses } W_c = 2915 - 25 = 2890 \text{ W}$$

**Full-load Condition**

If  $I_a$  is the full-load armature current, then full-load motor input current is  $(I_a + 2.55) \text{ A}$ .

$$\text{F.L. motor power input} = 220 (I_a + 2.55) \text{ W}$$

This input must be equal to the sum of

- (i) output = 44.76 kW = 44,760 W
- (ii) brush loss =  $2I_a$  watt
- (iii)  $W_c = 2,890 \text{ W}$
- (iv) Arm. Cu loss =  $0.032 I_a^2$

$$\begin{aligned} \therefore 220(I_a + 2.55) &= 44,750 + 2,890 + 2I_a + 0.032I_a^2 \\ \text{or } 0.032I_a^2 - 218I_a + 47,090 &= 0 \\ \text{or } I_a &= \frac{218 \pm \sqrt{218^2 - 4 \times 0.032 \times 47,090}}{2 \times 0.032} = 223.5 \text{ A} \\ \text{Line input current } I &= I_a + I_{sh} = 223.5 + 2.55 = \mathbf{226 \text{ A}} \\ \text{F.L. power input} &= 226 \times 220 = 49,720 \text{ W} \\ \therefore \text{F.L. efficiency} &= 44,760/49,720 = 0.9 \text{ or } \mathbf{90\%}. \end{aligned}$$

**Example 31.6.** A 200-V, shunt motor develops an output of 17.158 kW when taking 20.2 kW. The field resistance is 50 Ω and armature resistance 0.06 Ω. What is the efficiency and power input when the output is 7.46 kW? **(Elect. Machines-I, Aligarh Muslim Univ. 1989)**

**Solution. In the first case :**

$$\begin{aligned} \text{Output} &= 17,158 \text{ W} & \text{Input} &= 20,200 \text{ W} \\ \text{Total losses} &= 20,200 - 17,158 = 3,042 \text{ W} ; \text{ Input current} &= 20,200/200 = 101 \text{ A} \\ I_{sh} &= 200/50 = 4 \text{ A} ; I_a = 101 - 4 = 97 \text{ A} \\ \therefore \text{Armature Cu loss} &= 97^2 \times 0.06 = 564.5 \text{ W} \\ \therefore \text{Constant losses} &= 3,042 - 564.5 = 2,477.5 = 2478 \text{ W (approx.)} \end{aligned}$$

**In the second case :**

$$\begin{aligned} \text{Let, } I_a &= \text{armature current} & \text{Input current} &= (I_a + 4) \text{ A} \\ \text{Now, input power} &= \text{output} + I_a^2 R_a + \text{constant losses} \\ \therefore 200(I_a + 4) &= 7,460 + 0.06 I_a^2 + 2,478 \\ \text{or } 0.06I_a^2 - 200I_a + 9,138 &= 0 \\ \therefore I_a &= \frac{200 \pm \sqrt{200^2 - 4 \times 0.06 \times 9,138}}{2 \times 0.06} = \frac{200 \pm 194}{0.12} = 3,283.3 \text{ A or } 46 \text{ A} \end{aligned}$$

We will reject the larger value because it corresponds to unstable operation of the motor. Hence, take  $I_a = 46 \text{ A}$ .

$$\begin{aligned} \therefore \text{Input current } I &= I_a + I_{sh} = 46 + 4 = 50 \text{ A} \\ \text{Power input} &= \frac{50 \times 200}{1000} = \mathbf{10 \text{ kW}} \quad \therefore \eta = \frac{7,460 \times 100}{10,000} = \mathbf{74.6\%} \end{aligned}$$

**Example 31.7.** A 200-V, 14.92 kW dc shunt motor when tested by the Swinburne method gave the following results :

*Running light : armature current was 6.5 A and field current 2.2 A. With the armature locked, the current was 70 A when a potential difference of 3 V was applied to the brushes. Estimate the efficiency of the motor when working under full-load conditions.*

**(Electrical Engg.-I, Bombay Univ. 1985)**

**Solution.** No-load input current = 6.5 + 2.2 = 8.7 A

$$\text{No-load power input} = 200 \times 8.7 = 1,740 \text{ W}$$

No-load input equals Cu losses and stray losses.

$$\text{Field Cu loss} = 200 \times 2.2 = 440 \text{ W}$$

$$\text{Armature Cu loss} = 6.5^2 \times 0.04286 = 1.8 \text{ W} \quad (\because R_a = 3/70 = 0.04286 \Omega)$$

$$\therefore \text{Constant losses} = 1,740 - 1.8 = 1738 \text{ W}$$

We will assume that constant losses are the same at full-load also.

$$\text{Let, } I_a = \text{full-load armature current}$$

$$\begin{aligned} \text{F.L. armature Cu loss} &= 0.04286 I_a^2 \text{ W ; Constant losses} = 1,738 \text{ W} \\ \text{F.L. total loss} &= 1,738 + 0.04286 I_a^2 \\ \text{F.L. output} &= 14,920 \text{ W ; F.L. input} = 200 (I_a + 2.2) \text{ W} \\ \text{We know,} & \quad \text{input} = \text{output} + \text{losses} \\ \text{or} & \quad 200 I_a + 440 = 14,920 + 1,738 + 0.04286 I_a^2 \\ \text{or} & \quad 0.04286 I_a^2 - 200 I_a + 16,218 = 0 \quad \therefore I_a = 82.5 \text{ A} \\ \therefore & \quad \text{Input current} = 82.5 + 2.2 = 84.7 \text{ A} \\ & \quad \text{F.L. power input} = 200 \times 84.7 \text{ A} = \mathbf{16,940 \text{ W}} \\ \therefore & \quad \eta = 14,920 \times 100 / 16,940 = \mathbf{88\%} \end{aligned}$$

**Example 31.8.** In a test on a d.c. shunt generator whose full-load output is 200 kW at 250 V, the following figures were obtained :

(a) When running light as a motor at full speed, the line current was 36 A, the field current 12 A, and the supply voltage 250.

(b) With the machine at rest, a p.d. of 6 V produced a current of 400 A through the armature circuit. Explain how these results may be utilised to obtain the efficiency of generator at full-load and half-load. Neglect brush voltage drop.

**Solution. At no-load :**

$$\begin{aligned} I_a &= 36 - 12 = 24 \text{ A ; } R_a = 6/400 = 0.015 \Omega \\ \therefore \text{Armature Cu loss} &= 24^2 \times 0.015 = 8.64 \text{ watt} \\ \text{No-load input} &= \text{total losses in machine} = 250 \times 36 = 9,000 \text{ W} \\ \text{Constant losses} &= 9,000 - 8.64 = \mathbf{8,991.4 \text{ W}} \end{aligned}$$

**At full-load :**

$$\begin{aligned} \text{Output} &= 200,000 \text{ W ; Output current} = 200,000/250 = 800 \text{ A ; } I_{sh} = 12 \text{ A} \\ \therefore \text{F.L. armature current} &= 800 + 12 = 812 \text{ A} \\ \therefore \text{F.L. armature Cu losses} &= 812^2 \times 0.015 = 9890 \text{ W} \\ \therefore \text{F.L. total losses} &= 9890 + 8,991.4 = 18881 \text{ W} \quad \therefore \eta = \frac{200,000 \times 100}{200,000 + 18,881} = \mathbf{91.4\%} \end{aligned}$$

**At half-load :**

$$\begin{aligned} \text{Output} &= 100,000 \text{ W ; Output current} = 100,000/250 = 400 \text{ A} \\ I_a &= 400 + 12 = 412 \text{ A} \quad \therefore I_a^2 R_a = 412^2 \times 0.015 = 2,546 \text{ W} \\ \text{Total losses} &= 8,991.4 + 2,546 = 11,537 \text{ W} \quad \therefore \eta = \frac{100,000 \times 100}{100,000 + 11,537} = \mathbf{89.6\%} \end{aligned}$$

**Example 31.9.** A 250-V, 14.92 kW shunt motor has a maximum efficiency of 88% and a speed of 700 r.p.m. when delivering 80% of its rated output. The resistance of its shunt field is 100 Ω. Determine the efficiency and speed when the motor draws a current of 78 A from the mains.

**Solution.** Full-load output = 14,920 W  
 80% of F.L. output = 0.8 × 14,920 = 11,936 W ; η = 0.88  
 Input = 11,936/0.88 = 13,564 W  
 Total losses = 13,564 - 11,936 = 1,628 W

As efficiency is maximum at this load, the variable loss is equal to constant losses.

$$\begin{aligned} \therefore W_c &= I_a^2 R_a = 1,628/2 \quad \therefore I_a^2 R_a = 814 \text{ W} \\ \text{Now, input current} &= 13,564/250 = 54.25 \text{ A} \\ \therefore I_{sh} &= 250/100 = 2.5 \text{ A} \quad \therefore I_a = 54.25 - 2.5 = 51.75 \text{ A} \end{aligned}$$

$$\therefore 51.75^2 R_a = 814 \quad \therefore R_a = 814/51.75^2 = 0.3045 \Omega$$

**When input current is 78 A**

$$I_a = 78 - 2.5 = 75.5 \text{ A} \quad \therefore I_a^2 R_a = 75.5^2 \times 0.3045 = 1,736 \text{ W}$$

$$\text{Total losses} = 1,736 + 814 = 2,550 \text{ W} ; \text{Input} = 250 \times 78 = 19,500 \text{ W}$$

$$\eta = \frac{19,500 - 2,550}{19,500} \times 100 = \mathbf{86.9\%}$$

**Speed :**

$$\frac{N_2}{N_1} = \frac{E_{b2}}{E_{b1}} \quad \text{or} \quad \frac{N_2}{700} = \frac{250 - (75.5 \times 0.3045)}{250 - (51.75 \times 0.3045)} = \frac{227}{234.25} ; N_2 = \mathbf{680 \text{ r.p.m.}}$$

### 31.5. Regenerative or Hopkinson's Test (Back-to-Back Test)

By this method, **full-load test** can be carried out on two shunt machines, preferably identical ones, without wasting their outputs. The two machines are mechanically coupled and are so adjusted electrically that one of them runs as a motor and the other as a generator. The mechanical output of the motor drives the generator and the electrical output of generator is used in supplying the greater part of input to the motor. If there were no losses in the machines, they would have run without any external power supply. But due to these losses, generator output is not sufficient to drive the motor and **vice-versa**. The losses are supplied either by an extra motor which is belt-connected to the motor-generator set or as suggested by Kapp, electrically from the supply mains.

Essential connections for the test are shown in Fig. 31.6. The two shunt machines are connected in parallel. They are, to begin with, started as unloaded motors. Then, the field of one is weakened and that of the other is strengthened so that the former runs as a motor and the latter as a generator. The usual method of procedure is as follows :

Machine *M* is started up from the supply mains with the help of a starter (not shown) whereas main switch *S* of the other machine is kept open. Its speed is adjusted to normal value by means of its shield regulator. Machine *M* drives machine *G* as a

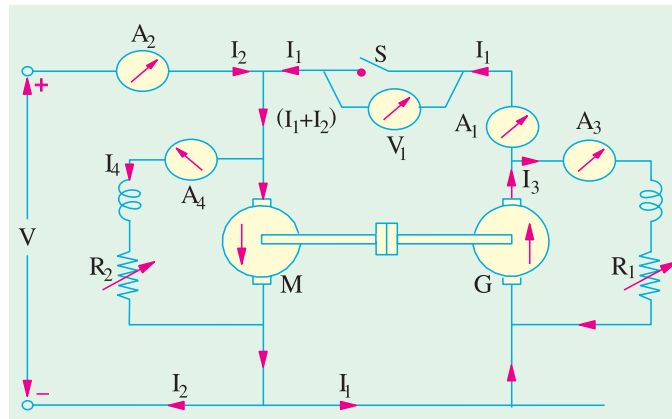

Fig. 31.6

Motor-cum generator set

generator and its voltage is read on voltmeter *V*<sub>1</sub>. The voltage of *G* is adjusted by its field regulator until voltmeter *V*<sub>1</sub> reads zero, thereby showing that its voltage is the same, both in polarity and magnitude as that of the main supply. Thereafter, *S* is closed to parallel the machines. By adjusting the respective field regulators, any load can now be thrown on to the machines. Generator current *I*<sub>1</sub> can be adjusted to any desired value by increasing the excitation of *G* or by reducing the excitation of *M* and the corresponding values of different ammeters are read.

ing the excitation of *M* and the corresponding values of different ammeters are read.

The electrical output of the generator **plus** the small power taken from the supply, is taken by the motor and is given out as a mechanical power **after** supplying the motor losses.

If supply voltage is  $V$ , then

$$\text{Motor input} = V(I_1 + I_2), \text{ where } I_2 \text{ is the current taken from the supply.}$$

$$\text{Generator output} = VI_1 \quad \dots(i)$$

**Assuming that both machines have the same efficiency  $\eta$ ,**

$$\text{Output of motor} = \eta \times \text{input} = \eta V(I_1 + I_2) = \text{generator input}$$

$$\text{Output of generator} = \eta \times \text{input} = \eta \times \eta V(I_1 + I_2) = \eta^2 V(I_1 + I_2) \quad \dots(ii)$$

Hence, from (i) and (ii), we get

$$\eta^2 V(I_1 + I_2) = VI_1 \quad \text{or} \quad \eta = \sqrt{\frac{I_1}{I_1 + I_2}}$$

However, it is not quite correct to assume equal efficiencies for two machines because their armature currents as well as excitations are different. We will not find the efficiencies separately.

Let  $R_a$  = armature resistance of each machine

$I_3$  = exciting current of the generator

$I_4$  = exciting current of the motor

Armature Cu loss in generator =  $(I_1 + I_3)^2 R_a$ ; Armature Cu loss in motor =  $(I_1 + I_2 - I_4)^2 R_a$

Shunt Cu loss in generator =  $VI_3$ ; Shunt Cu loss in motor =  $VI_4$

But total motor and generator losses are equal to the power supplied by the mains.

Power drawn from supply =  $VI_2$

If we subtract the armature and shunt Cu losses from this, we get the stray losses of *both* machines.

$\therefore$  Total stray losses for the set

$$= VI_2 - [(I_1 + I_3)^2 R_a + (I_1 + I_2 - I_4)^2 R_a + VI_3 + VI_4] = W \text{ (say)}$$

Making one assumption that stray losses are equally divided between the two machines, we have

Stray loss per machine =  $W/2$

**For Generator**

$$\text{Total losses} = (I_1 + I_3)^2 R_a + VI_3 + W/2 = W_g \text{ (say)}$$

$$\text{Output} = VI_1 \quad \therefore \quad \eta_g = \frac{VI_1}{VI_1 + W_g}$$

$$\text{Total losses} = (I_1 + I_2 - I_4)^2 R_a + VI_4 + W/2 = W_m \text{ (say)}$$

$$\text{Input} = V(I_1 + I_2) \quad \therefore \quad \eta_m = \frac{V(I_1 + I_2) - W_m}{V(I_1 + I_2)}$$

### 31.6. Alternative Connections for Hopkinson's Test

In Fig. 31.7 is shown in slightly different method of connecting the two machines to the supply. Here, the main difference is that the shunt windings are directly connected across the lines. Hence, the line input current is  $I_1$  **excluding the field currents**. The efficiencies can be calculated as detailed below :

Motor armature Cu loss =  $(I_1 + I_2)^2 R_a$ ; Generator armature Cu loss =  $I_2^2 R_a$

Power drawn from the supply =  $VI_1$

$\therefore$  Total stray losses *i.e.* iron, friction and windage losses for the two machines are

$$= VI_1 - [(I_1 + I_2)^2 R_a - I_2^2 R_a] = W \text{ (say)}$$

∴ stray loss for each machine =  $W/2$

**Motor Efficiency**

$$\begin{aligned} \text{Motor input} &= \text{armature input} + \text{shunt field input} = V(I_1 + I_2) + VI_3 + W_{input} \\ \text{Motor losses} &= \text{armature Cu loss} + \text{shunt Cu loss} + \text{stray losses} \\ &= (I_1 + I_2)^2 R_a + VI_3 + W/2 = W_m \text{ (say)} \end{aligned}$$

$$\text{Motor } \eta = \frac{W_{input} - W_m}{W_{input}} \times 100$$

**Generator Efficiency**

$$\text{Generator output} = VI_2 ; \text{Generator losses} = I_2^2 R_a + VI_4 + W/2 = W_g \text{ (say)}$$

$$\therefore \text{Generator } \eta = \frac{VI_2}{VI_2 + W_g}$$

**31.7. Merits of Hopkinson's Test**

1. Power required for the test is small as compared to the full-load powers of the two machines.
2. As machines are being tested under full-load conditions, the temperature rise and the commutation qualities of the machines can be observed.

Fig. 31.7

3. Because of full-load conditions, any change in iron loss due to flux distortion at full-load, is being taken into account.

The only disadvantage is with regard to the availability of two identical machines.

**Example 31.10 (a).** In a Hopkinson's test on two 220-V, 100-kW generators, the circulating current is equal to the full-load current and, in addition, 90 A are taken from the supply. Obtain the efficiency of each machine.

**Solution.** Output current of the generator

$$I_1 = \frac{100,000}{220} = \frac{5,000}{11} = 454.4 \text{ A}, I_2 = 90 \text{ A}$$

Assuming equal efficiencies, from Art. 29.5, we have

$$\eta = \sqrt{\frac{I_1}{I_1 + I_2}} = \sqrt{\frac{454.5}{454.5 + 90}} = 0.914 \text{ or } \mathbf{91.4\%}$$

**Example 31.10 (b).** In the Hopkinson's test on two d.c. machines, machine A has a field current of 1.4 A and machine B has a field current of 1.3 A. Which machine acts as a generator ?

(Bharathithasan University April 1997)

**Solution.** In Hopkinson's test (on two identical d.c. shunt machines), since the two machines are coupled, the speed is common and is decided by the field current of the motor. The field windings of both the machines are in parallel with a separate D.C. source.

Since the machines are identical and are running at the **same speed**, their e.m.fs are in proportion to their field currents.

$$\frac{\text{E.M.F. induced in the armature of machine A}}{\text{E.M.F. induced in the armature of machine B}} = \frac{1.4}{1.3}$$

$$E_A = (1.4/1.3) \times E_B = 1.077 E_B$$

Since  $E_A$  is larger than  $E_B$ , Machine A supplies power to Machine B. It means, A is working as a generator, and B is motoring.

**Example 31.11.** Two shunt machines loaded for the Hopkinson's test take 15 A at 200 V from the supply. The motor current is 100 A and the shunt currents are 3 A and 2.5 A. If the armature resistance of each machine is 0.05 ohm, calculate the efficiency of each machine for this particular load-condition. (Bharathithasan Univ. April 1997)

**Solution.** Line current into armature circuits = 15 A, Motor armature copper-loss = 500 W

Motor-armature-current = 100 A, Generator armature copper loss = 361 W

Hence generator-armature-current = 85 A

For each machine, No load Mechanical losses + Core-loss + Stray losses

$$= \frac{1}{2}(VI_a - I_{am}^2 r_{am} - I_{ag}^2 r_{ag})$$

$$= \frac{1}{2}(200 \times 15 - 100^2 \times 0.05 - 85^2 \times 0.05)$$

$$= \frac{1}{2}(3000 - 500 - 361) = 1069.5 \text{ W}$$

Motor field copper-loss =  $200 \times 3 = 600 \text{ W} \cong 1.07 \text{ kW}$

Generator field copper-loss =  $200 \times 2.5 = 500 \text{ W}$

Total Losses in motor =  $600 + 1069.5 + 500 = 2169.5 \text{ W}$

Total Losses in Generator =  $500 + 1069.5 + 361 = 1931 \text{ W}$

$$\text{Efficiency of motor} = \frac{\text{Motor output}}{\text{Motor input}} \times 100\%$$

Motor Input : (a)  $200 \times 100 = 20 \text{ kW}$  to armature

(b)  $0.6 \text{ kW}$  to field winding

Total Input to motor =  $20.6 \text{ kW}$

From armature side, losses to be catered are :

(i) Stray losses + No Load Mech. Losses + Core Losses =  $1.07 \text{ kW}$

(ii) Armature copper-loss =  $0.5 \text{ kW}$

Motor Output from armature =  $20 - 0.5 - 1.07 = 18.43 \text{ kW}$

$$\text{Motor efficiency} = \frac{18.43}{20.6} \times 100\% = 89.47\%$$

Generator armature output =  $200 \times 85 \times 10^{-3} = 17 \text{ kW}$

Generator losses : (a) Field wdg :  $0.5 \text{ kW}$

(b) Total no-load-losses :  $1.07 \text{ kW}$

(c) armature copper-loss =  $0.36 \text{ kW}$

Total losses in Generator =  $1.93 \text{ kW}$

$$\text{Generator efficiency} = \frac{17}{17 + 1.93} \times 100\% = 89.80\%$$

**Special Note:** 15 A current for d.c. supply is related here to armature-input for two machines which are under back-to-back regenerative tests. There are different variations in handling and giving the test data. It is always desirable to draw the circuit diagram according to which the calculations are being related.

**Example 31.12.** The Hopkinson's test on two similar shunt machines gave the following full-load data :

Line voltage	= 110 V	Field currents are 3 A and 3.5 A
Line current	= 48 A	Arm. resistance of each is 0.035 Ω
Motor arm. current	= 230 A	

Calculate the efficiency of each machine assuming a brush contact drop of 1 volt per brush.

(Electrical Machines, Nagpur Univ. 1992)

**Solution.** The motor-generator set is shown in Fig. 31.8. It should also be noted that the machine with lesser excitation is motoring. We will find the total armature Cu losses and brush contact loss for both machines.

**Motor**

$$\begin{aligned} \text{Arm. Cu loss} &= 230^2 \times 0.035 = 1,851.5 \text{ W} \\ \text{Brush contact loss} &= 230 \times 2 = 460 \text{ W} \\ \text{Total arm. Cu loss} &= 1851.5 + 460 = 2,312 \text{ W} \\ \text{Shunt Cu loss} &= 110 \times 3 = 330 \text{ W} \\ \text{Total Cu loss} &= 2,312 + 330 = 2,642 \text{ W} \end{aligned}$$

**Generator**

$$\begin{aligned} \text{Generator arm. current} &= 233 - 48 + 3.5 \\ &= 188.5 \text{ W} \\ \text{Arm. Cu loss} &= 188.5^2 \times 0.035 = 1,244 \text{ W} \\ \text{Brush contact Cu loss} &= 188.5 \times 2 = 377 \text{ W} \\ \text{Total arm. Cu loss} &= 1,244 + 377 = 1,621 \text{ W} \\ \text{Shunt Cu loss} &= 110 \times 3.5 = 385 \text{ W} ; \\ \text{Total Cu loss} &= 1,621 + 385 = 2,006 \text{ W} \end{aligned}$$

**For the Set**

$$\begin{aligned} \text{Total arm. and shunt Cu loss for the set} &= 2,642 + 2,006 = 4,648 \text{ W} \\ \text{Total input} &= 110 \times 48 = 5,280 \text{ W} ; \text{ Stray losses for the set} = 5,280 - 4,648 = 632 \text{ W} \\ \text{Stray losses per machine} &= 632/2 = 316 \text{ W} \end{aligned}$$

**Motor Efficiency**

$$\begin{aligned} \text{Arm. Cu + brush drop loss} &= 2,312 \text{ W} & \text{Shunt Cu loss} &= 330 \text{ W} \\ \text{Stray losses} &= 316 \text{ W} & \text{Total loss} &= 2,312 + 330 + 316 = 2,958 \text{ W} \\ \text{Motor input} &= 110 \times 233 = 25,630 \text{ W} ; \text{ Motor output} &= 25,630 - 2,958 = 22,672 \end{aligned}$$

$$\therefore \eta = 22,672 \times 100/25,630 = \mathbf{88.8\%}$$

**Generator Efficiency**

$$\begin{aligned} \text{Total losses} &= 2,006 + 316 = 2,322 \text{ W} ; \text{ Output} = 110 \times 185 = 20,350 \text{ W} \\ \text{Generator input} &= 20,350 + 2,322 = 22,672 \text{ W} = \text{motor input} \\ \eta &= 20,350/22,672 = 0.894 \text{ or } \mathbf{89.4\%} \end{aligned}$$

Fig. 31.8

**Example 31.13.** In a Hopkinson's test on a pair of 500-V, 100-kW shunt generators, the following data was obtained :

Auxiliary supply, 30 A at 500 V : Generator output current, 200 A  
 Field currents, 3.5 A and 1.8 A  
 Armature circuit resistances, 0.075Ω each machine. Voltage drop at brushes, 2 V (each machine).  
 Calculate the efficiency of the machine acting as a generator.

(Elect. Technology-1, Gwalior Univ. 1986)

**Solution.** Motor arm. current = 200 + 30 = 230 A, as shown in Fig. 31.9.

$$\text{Motor arm. Cu loss} = 230^2 \times 0.075 + 230 \times 2 = 4,428 \text{ W}$$

$$\text{Motor field Cu loss} = 500 \times 1.8 = 900 \text{ W}$$

$$\text{Generator arm. Cu loss} = 200^2 \times 0.075 + 200 \times 2 = 3,400 \text{ W}$$

$$\text{Generator field Cu loss} = 500 \times 3.5 = 1,750 \text{ W}$$

Total Cu loss for two machines

$$= 4,428 + 900 + 3400 + 1750$$

$$= 10,478 \text{ W}$$

Power taken from auxiliary supply

$$= 500 \times 30 = 15,000 \text{ W}$$

Stray losses for the two machines

$$= 15,000 - 10,478 = 4,522 \text{ W}$$

Stray loss per machine = 4,522/2 = 2,261 W

Total losses in generator = 3400 + 1750 + 2261 = 7,411 W

$$\text{Generator output} = 500 \times 200 = 100,000 \text{ W}$$

$$\therefore \eta_g = \frac{\text{output}}{\text{output} + \text{losses}} = \frac{100,000}{107,411} \times 100 = \mathbf{93.09\%}$$

Fig. 31.9

**Example 31.14.** Explain the Hopkinson's test on a pair of shunt motors.

In such a test on 250-V machines, the line current was 50 A and the motor current 400 A not including the field currents of 6 A and 5 A. The armature resistance of each machine was 0.015 Ω. Calculate the efficiency of each machine. (Adv. Elect. Machines, A.M.I.E. Sec. B, 1991)

**Solution.** The connections are shown in Fig. 31.10.

$$\text{Motor armature Cu loss} = 400^2 \times 0.015 = 2,400 \text{ W}$$

$$\text{Generator armature Cu loss} = 350^2 \times 0.015 = 1,838 \text{ W}$$

$$\text{Power drawn from supply} = 250 \times 50 = 12,500 \text{ W}$$

∴ Iron, friction and windage losses for the two machines

$$= 12,500 - (2,400 + 1,838)$$

$$= 8,262 \text{ W}$$

Iron, friction and windage loss per machine

$$= 8,262/2 = 4,130 \text{ W* (approx.)}$$

Fig. 31.10

### Motor Losses and Efficiency

$$\text{Motor arm. Cu loss} = 2,400 \text{ W} ; \text{ Motor field Cu loss} = 250 \times 5 = 1,250 \text{ W}$$

$$\text{Iron, friction and windage losses} = 4,130 \text{ W}$$

$$\text{Total motor losses} = 2,400 + 1,250 + 4,130 = 7,780 \text{ W}$$

$$\text{Motor input} = 250 \times 400 + 250 \times 5 = 101,250 \text{ W}$$

$$\therefore \text{ Motor efficiency} = (101,250 - 7,780)/101,250 = 0.923 \text{ or } \mathbf{92.3\%}$$

\* We could also get this value as follows :

$$\text{Total supply input} = 250 \times 61 = 15,250 \text{ W} ; \text{ Gen. and motor field Cu loss} = 250 \times 6 + 250 \times 5 = 2,750 \text{ W}$$

Iron, friction and windage losses for both machines

$$= 15,250 - (2,400 + 1,838 + 2,750) = \mathbf{8,262 \text{ W}} \quad \text{-- as before}$$

### Generator Losses and Efficiency

Generator arm. Cu loss = 1,838 W ; Generator field Cu loss =  $250 \times 6 = 1,500$  W  
 Iron, friction and windage loss = 4,130 W  
 Total losses =  $1,838 + 1,500 + 4,130 = 7,468$  W  
 Generator output =  $250 \times 350 = 87,500$  W  
 $\therefore$  Generator efficiency =  $(87,500 - 7,468)/87,500 = 0.915$  or **91.5%**

**Example 31.15.** The Hopkinson's test on two shunt machines gave the following results for full-load :

Line voltage = 250 V ; current taken from supply system excluding field currents = 50 A ; motor armature current = 380 A ; field currents 5 A and 4.2 A. Calculate the efficiency of the machine working as a generator. Armature resistance of each machine is 0.2  $\Omega$ .

(Electrical Machinery-I Mysore Univ. 1988)

**Solution.** The connections are shown in Fig. 31.11.

Motor arm. Cu loss =  $380^2 \times 0.02 = 2,888$  W  
 Generator arm. Cu loss =  $330^2 \times 0.02 = 2,178$  W  
 Power drawn from supply =  $250 \times 50 = 12,500$  W  
 Stray losses for the two machines  
 =  $12,500 - (2,888 + 2,178) = 7,434$  W  
 Stray losses per machine =  $7,434/2 = 3,717$  W

### Motor Efficiency

Arm. Cu loss = 2,888 W  
 Field Cu loss =  $250 \times 4.2 = 1050$  W  
 Stray losses = 3,717 W  
 Total loss =  $2,888 + 1050 + 3,717 = 7,655$  W  
 Motor input =  $250 \times 380 + 250 \times 4.2 = 96,050$  W  
 Motor output =  $96,050 - 7,655 = 88,395$  W  
 $\therefore \eta = 88,395/96,050 = 0.9203$  or **92.03%**

### Generator Efficiency

Arm. Cu loss = 2,178 W ; Field Cu loss =  $250 \times 5 = 1250$  W  
 Stray losses = 3,717 W ; Total losses = 7,145 W  
 Generator output =  $250 \times 330 = 82,500$  W  
 Generator input =  $82,500 + 7,145 = 89,645$  W  
 $\eta = 82,500/89,645 = 0.9202$  or **92.02%**

Fig. 31.11

## 31.8. Retardation or Running Down Test

This method is applicable to shunt motors and generators and is **used for finding stray losses**. Then, knowing the armature and shunt Cu losses at a given load current, efficiency can be calculated.

The machine under test is speeded up slightly beyond its normal speed and then supply is cut off from the armature while keeping the field excited. Consequently, the armature slows down and its kinetic energy is used to meet the **rotational losses i.e.** friction, windage and iron losses.\*

Kinetic energy of the armature is  $K.E. = \frac{1}{2} I\omega^2$

where  $I$  = moment of inertia of the armature and  $\omega$  = angular velocity

$\therefore$  Rotational losses,  $W$  = Rate of loss of  $K.E.$

\* If armature slows down with no excitation, then energy of the armature is used to overcome mechanical losses only, there being no iron losses (see Ex. 31.19).

$$\therefore W = \frac{d}{dt} \left( \frac{1}{2} I \omega^2 \right) = I \omega \cdot \frac{d\omega}{dt}$$

Two quantities need be known (i) moment of inertia ( $I$ ) of the armature and (ii)  $\frac{d\omega}{dt}$  or  $\frac{dN}{dt}$  because  $\omega \propto N$ . These are found as follows :

**(a) Finding  $\frac{d\omega}{dt}$**

Fig. 31.12

Fig. 31.13

As shown in Fig. 31.12, a voltmeter  $V$  is connected across the armature. This voltmeter is used as a speed indicator by suitably graduating it, because  $E \propto N$ . When supply is cut off, the armature speed and hence voltmeter reading falls. By noting different amounts of voltage fall in different amounts of time, a curve is drawn between time and the speed (obtained from voltage values) as shown in Fig. 31.13.

From any point  $P$  which corresponds to normal speed, a tangent  $AB$  is drawn.

Then 
$$\frac{dN}{dt} = \frac{OB \text{ (in r.p.m.)}}{OA \text{ (in seconds)}}$$

From (i), above 
$$W = I \omega \frac{d\omega}{dt}$$

Now 
$$\omega = \frac{2\pi N}{60} \quad \dots (N \text{ in r.p.m.})$$

$$W = I \left( \frac{2\pi N}{60} \right) \times \frac{d}{dt} \left( \frac{2\pi N}{60} \right); W = \left( \frac{2\pi}{60} \right)^2 I.N. \frac{dN}{dt} = 0.011 I.N. \frac{dN}{dt} \quad \dots (ii)$$

**(ii) Finding Moment of Inertia (I)**

**(a) First Method—where  $I$  is calculated.**

First, slowing down curve is drawn with armature alone. Next, a fly-wheel of known moment of inertia  $I_1$  is keyed onto the shaft and slowing down curve is drawn again. Obviously, slowing down time will be longer due to combined increased moment of inertia of the two. For any given speed,  $(\frac{dN}{dt}_1)$  and  $(\frac{dN}{dt}_2)$  are determined as before. It should be noted that the losses in both cases would be almost the same, because addition of a fly-wheel will not make much difference to the losses.

Hence, from equation (ii) above

In the first case, 
$$W = \left( \frac{2\pi}{60} \right)^2 I N \left( \frac{dN}{dt}_1 \right)$$

Shunt wound generator

In the second case,  $W = \left(\frac{2\pi}{60}\right)^2 (I + I_1) N \times \left(\frac{dN}{dt_2}\right)$

$$\therefore (I + I_1) \left(\frac{dN}{dt_2}\right) = I \left(\frac{dN}{dt_1}\right) \text{ or } \left(\frac{I + I_1}{I}\right) = \left(\frac{dN}{dt_1}\right) / \left(\frac{dN}{dt_2}\right)$$

$$\therefore I = I_1 \times \frac{(dN/dt_2)}{(dN/dt_1) - (dN/dt_2)} = I_1 \frac{dt_1}{dt_2 - dt_1}; I = I_1 \frac{t_1}{t_2 - t_1}$$

**(b) Second Method—where  $I$  is eliminated.**

In this method, first, time taken to slow down, say by 5%, is noted with armature alone. Next, a retarding torque—mechanical or preferably electrical, is applied to the armature and again time is noted. The method using electrical torque is shown in Fig. 31.12. The double-throw switch  $S$  while cutting off the armature from supply, automatically joins it to a non-inductive resistance  $R$  as shown. The power drawn by this resistance acts as a retarding torque on the armature, thereby making it slow down comparatively quickly. The additional loss is  $I_a^2 (R_a + R)$  or  $VI_a$ ,

where  $I_a =$  average current through  $R$ ;  $V =$  average voltage across  $R$ .

Let  $W'$  be this power. Then from (i) above

$$\left. \begin{aligned} W &= \left(\frac{2\pi}{60}\right)^2 I.N. \frac{dN}{dt_1} \\ W + W' &= \left(\frac{2\pi}{60}\right)^2 I.N. \frac{dN}{dt_2} \end{aligned} \right\} \text{If } dN \text{ is the same}$$

$$\therefore \frac{W + W'}{W} = \frac{dt_1}{dt_2} \quad \therefore W = W' \times \frac{dt_2}{dt_1 - dt_2} \text{ or } W = W' \times \frac{t_2}{t_1 - t_2}$$

where  $\frac{dN}{dt_1} =$  rate of change of speed **without** extra load

$\frac{dN}{dt_2} =$  rate of change of speed **with** extra electrical load.

**Example 31.16.** In a retardation test on a separately-excited motor, the induced e.m.f. in the armature falls from 220 V to 190 V in 30 seconds on disconnecting the armature from the supply. The same fall takes place in 20 seconds if, immediately after disconnection, armature is connected to a resistance which takes 10 A (average) during this fall. Find stray losses of the motor.

(Adv. Elect. Machines, A.M.I.E. Sec. B, 1992)

**Solution.** Let  $W =$  stray losses (mechanical and magnetic losses)

Average voltage across resistance =  $(200 + 190)/2 = 195$  V, Average current = 10 A

$\therefore$  Power absorbed  $W' = 1950$  W

Using the relation  $\frac{W}{W'} = \frac{t_2}{t_1 - t_2}$ ; we get  $W = 1950 \times \frac{20}{30 - 20} = 3,900$  watt

**Example 31.17.** In a retardation test on a d.c. motor, with its field normally excited, the speed fell from 1525 to 1475 r.p.m. in 25 seconds. With an average load of 1.0 kW supplied by the armature, the same speed drop occurred in 20 seconds. Find out the moment of inertia of the rotating parts in  $\text{kg.m}^2$ .

(Electrical Machines-III, Gujarat Univ. 1984)

**Solution.** As seen from Art. 31.8 (ii) (b).

$$W' = \left(\frac{2\pi}{60}\right)^2 I.N. \frac{dN}{dt}. \text{ Also } W = W' \times \frac{t_2}{t_1 - t_2}$$

Here,  $W' = 1$  kW = 1000 W,  $t_1 = 25$  second,  $t_2 = 20$  second

$$\begin{aligned} \therefore W &= 1000 \times 20 / (25 - 20) = 4000 \text{ W} \\ \text{Now, } N &= 1500 \text{ r.p.m. (average speed) ; } dN = 1525 - 1475 = 50 \text{ r.p.m. ; } dt = 25 \\ \therefore 4000 &= (2\pi/60)^2 I \cdot 1500 \times 50 / 25 \quad \therefore I = \mathbf{121.8 \text{ kg.m}^2}. \end{aligned}$$

**Example 31.18.** A retardation test is made on a separately-excited d.c. machine as a motor. The induced voltage falls from 240 V to 225 V in 25 seconds on opening the armature circuit and 6 seconds on suddenly changing the armature connection from supply to a load resistance taking 10 A (average). Find the efficiency of the machines when running as a motor and taking a current of 25 A on a supply of 250 V. The resistance of its armature is 0.4 Ω and that of its field winding is 250 Ω.

(Elect. Technology, Allahabad Univ. 1991)

**Solution.** Average voltage across load

$$= (240 + 225) / 2 = 232.5 \text{ V ; } I_{av} = 10 \text{ A}$$

$$\therefore \text{ Power absorbed } W' = 232.5 \times 10 = 2,325 \text{ W}$$

and  $t_1 = 30 \text{ second, } t_2 = 6 \text{ second ; } W = \text{stray loss}$

Using  $\frac{W}{W'} = \frac{t_2}{t_1 - t_2} = \mathbf{734.1 \text{ W}}$ , we get

Stray losses  $W = 2325 \times \frac{6}{25 - 6} = \mathbf{734.1 \text{ W}}$

$$\text{Input current} = 25 \text{ A ; } I_{sh} = 250 / 250 = 1 \text{ A ; } I_a = 25 - 1 = 24 \text{ A}$$

$$\text{Armature Cu loss} = 24^2 \times 0.4 = 230.4 \text{ W ; Shunt Cu loss} = 250 \times 1 = 250 \text{ W}$$

$$\therefore \text{ Total losses} = 734.1 + 230.4 + 250 = 1,215 \text{ W (approx.)}$$

$$\text{Input} = 250 \times 25 = 6,250 \text{ W ; Output} = 6,250 - 1,215 = 5,035 \text{ W}$$

$$\therefore \eta = 5,035 / 6,250 = 0.806 \text{ or } \mathbf{80.6\%}$$

**Example 31.19.** A retardation test is carried out on a 1000 r.p.m. d.c. machine. The time taken for the speed to fall from 1030 r.p.m. to 970 r.p.m. is :

(a) 36 seconds with no excitation

(b) 15 seconds with full excitation and

(c) 9 seconds with full excitation and the armature supplying an extra load of 10 A at 219 V.

Calculate (i) the moment of inertia of the armature in kg. m<sup>2</sup> (ii) iron losses and (iii) the mechanical losses at the mean speed of 1000 r.p.m.

**Solution.** It should be noted that

(i) when armature slows down with no excitation, its kinetic energy is used to overcome mechanical losses only ; because due to the absence of flux, there is no iron loss.

(ii) with excitation, kinetic energy is used to supply mechanical and iron losses collectively known as stray losses.

(iii) If  $I$  is taken in kg-m<sup>2</sup> unit, then rate of loss of energy is in watts.

$$\text{Mechanical loss} \quad W_m = \left(\frac{2\pi}{60}\right)^2 I \cdot N \cdot \frac{dN}{dt} \quad \dots \text{Art. 31.8}$$

Here  $dN = 1030 - 970 = 60 \text{ r.p.m., } dt = 36 \text{ seconds, } N = 1000 \text{ r.p.m.}$

$$W_m = \left(\frac{2\pi}{60}\right)^2 I \cdot N \cdot \frac{60}{36} \quad \dots \text{(i)}$$

Similarly  $W_s = \left(\frac{2\pi}{60}\right)^2 I \cdot N \cdot \frac{60}{15} \quad \dots \text{(ii)}$

$$\text{Also } W_s = W' \frac{t_2}{t_1 - t_2} = 219 \times 10 \times \frac{9}{15 - 9} = 3,285 \text{ W}$$

Using equation (ii), we get

$$3,285 = \left(\frac{2\pi}{60}\right)^2 \times I \times 1000 \times \frac{60}{15}$$

(i) ∴  $I = 75 \text{ kg.m}^2$

Dividing (i) by (ii), we get  $\frac{W_m}{W_s} = \frac{15}{36}$

(ii) ∴  $W_m = 3,285 \times 15/36 = 1,369 \text{ W}$

(iii) ∴ Iron losses =  $W_s - W_m = 3,285 - 1,369 = 1,916 \text{ W}$

### 31.9. Field's Test for Series Motor

This test is applicable to two similar **series motors**. Series motors which are mainly used for traction work are easily available in pairs. The two machines are coupled mechanically.

One machine runs normally as a motor and drives generator whose output is wasted in a variable load  $R$  (Fig. 31.14). Iron and friction losses of two machines are made equal (i) by joining the series field winding of the generator in the motor armature circuit so that both

Fig. 31.14

Micro series motors

machines are equally excited and (ii) by running them at equal speed. Load resistance  $R$  is varied till the motor current reaches its full-load value indicated by ammeter  $A_1$ . After this adjustment for full-load current, different ammeter and voltmeter readings are noted.

Let  $V$  = supply voltage ;  $I_1$  = motor current ;  $V_2$  = terminal p.d. of generator ;  $I_2$  = load current.

∴ Intake of the whole set =  $V I_1$  ; output =  $V_2 I_2$ .

Total losses in the set,  $W_t = V I_1 - V_2 I_2$

Armature and field Cu losses  $W_{cu} = (R_a + 2R_{se}) I_1^2 + I_2^2 R_a$

where  $R_a$  = hot armature resistance of each machine

$R_{se}$  = hot series field resistance of each machine

∴ Stray losses for the set =  $W_t - W_{cu}$

Stray losses per machine  $W_s = \frac{W_t - W_{cu}}{2}$

Stray losses are equally divided between the machines because of their equal excitation and speed.

#### Motor Efficiency

Motor input =  $V_1 I_1$

Motor losses = armature + field Cu losses + stray losses

=  $(R_a + R_{se}) I_1^2 + W_s = W_m$  (say)

$$\eta_m = \frac{V_1 I_1 - W_m}{V_1 I_1}$$

**Generator Efficiency**

The generator efficiency will be of little use because it is running under abnormal conditions of *separate* excitation. However, the efficiency under these unusual conditions can be found if desired.

$$\begin{aligned} \text{Generator output} &= V_2 I_2 \\ \text{Field Cu loss} &= I_1^2 R_{se} \quad (\because \text{Motor current is passing through it.}) \\ \text{Armature Cu loss} &= I_2^2 R_a; \text{ Stray losses} = W_s \\ \text{Total losses} &= I_1^2 R_{se} + I_2^2 R_a + W_s = W_g \text{ (say)} \end{aligned}$$

$$\eta_g = \frac{V_2 I_2}{V_2 I_2 + W_g}$$

It should be noted that although the two machines are mechanically coupled yet it is not a regenerative method, because the generator output is wasted instead of being fed back into the motor as in Hopkinson’s (back-to-back) test.

**Example 31.20.** A test on two coupled similar tramway motors, with their fields connected in series, gave the following results when one machine acted as a motor and the other as a generator:

Motor : Armature current = 56 A ; Armature voltage = 590 V  
Voltage drop across field winding = 40 V

Generator : Armature current = 44 A ; Armature voltage = 400 V  
Field voltage drop = 40 V ; Resistance of each armature = 0.3 Ω

Calculate the efficiency of the motor and gearing at this load.

(Elect. Machinery-II, Nagpur Univ. 1992 & JNTU, Hyderabad, 2000)

**Solution.** The connection for the two machines are shown in Fig. 31.15.

$$\text{Total input} = 630 \times 56 = 35,280 \text{ W}$$

$$\text{Output} = 400 \times 44 = 17,600 \text{ W}$$

Total losses in the two machines are

$$= 35,280 - 17,600 = 17,680 \text{ W}$$

Series field resistance

$$\begin{aligned} R_{se} &= 40/56 \\ &= 0.714 \text{ } \Omega \end{aligned}$$

$$\begin{aligned} \text{Total Cu loss} &= (0.3 + 2 \times 0.714) \times 56^2 + 44^2 \\ &\times 0.3 = 5,425 + 581 = 6,006 \text{ W} \end{aligned}$$

$$\begin{aligned} \text{Stray losses of the set} &= 17,680 - 6,006 \\ &= 11,674 \text{ W} \end{aligned}$$

$$\therefore \text{ Stray losses/machine} = 11,674/2 = 5,837 \text{ W}$$

**Motor Efficiency**

$$\begin{aligned} \text{Motor armature input} &= \text{arm. voltage} \times \text{motor} \\ \text{current} &= 590 \times 56 = 33,040 \text{ W} \end{aligned}$$

Armature circuit Cu loss

$$= (0.3 + 0.714) \times 56^2 = 3,180 \text{ W}$$

$$\text{Stray loss} = 5,837 \text{ W} - \text{found above}$$

$$\text{Total losses} = 3,180 + 5,837 = 9,017 \text{ W, Output} = 33,040 - 9,017 = 24,023 \text{ W}$$

$$\therefore \eta_m = 24,023/33,040 = 0.727 \text{ or } 72.7\%$$

Fig. 31.15

**Generator Efficiency**

$$\text{Armature Cu loss} = 44^2 \times 0.3 = 581 \text{ W, Series field Cu loss} = 40 \times 56 = 2,240 \text{ W}$$

$$\text{Stray losses} = 5,837 \text{ W ; Total losses} = 581 + 2,240 + 5,837 = 8,658 \text{ W}$$

$$\text{Output} = 400 \times 44 = 17,600 \text{ W}$$

$$\therefore \eta_g = 17,600 / (17,600 + 8,658) = 0.67 \text{ or } 67\%$$

**Tutorial Problem No. 31.1**

1. A 500-V, shunt motor takes a total current of 5 A when running unloaded. The resistance of armature circuit is  $0.25 \Omega$  and the field resistance is  $125 \Omega$ . Calculate the efficiency and output when the motor is loaded and taking a current of 100 A. **[90.4% ; 45.2 kW]**

2. A d.c. shunt motor rated at 12.5 kW output runs at no-load at 1000 r.p.m. from a 250-V supply consuming an input current of 4 A. The armature resistance is  $0.5 \Omega$  and shunt field resistance is  $250 \Omega$ . Calculate the efficiency of the machine when delivering full-load output of 12.5 kW while operating at 250 V. **[81.57%] (Elect. Technology-I Madras Univ. 1979)**

3. The following results were obtained during Hopkinson's test on two similar 230-V machines; armature currents 37 A and 30 A; field currents 0.85 A and 0.8 A. Calculate the efficiencies of machines if each has an armature resistance of  $0.33 \Omega$ . **[Generator 87.9%, Motor 87.7%]**

4. In a Field's test on two 230-V, 1.492 kW mechanically-coupled similar series motors, the following figures were obtained. Each has armature and compole winding resistance of  $2.4 \Omega$ , series field resistance of  $1.45 \Omega$  and total brush drop of 2 V. The p.d. across armature and field was 230 V with a motor current of 10.1 A. The generator supplied a current of 8.9 A at a terminal p.d. of 161 V. Calculate the efficiency and output of the motor for this load. **[76.45%, 1.775 kW]**

5. Describe the Hopkinson's test for obtaining the efficiency of two similar shunt motors. The readings obtained in such a test were as follows; line voltage 100 V; motor current 30 A; generator current 25 A; armature resistance of each machine  $0.25 \Omega$ . Calculate the efficiency of each machine from these results, ignoring the field currents and assuming that their iron and mechanical losses are the same.

**[Motor 90.05%, Generator 92.5%]**

6. The Hopkinson's test on two similar d.c. shunt machines gave the following results :

Line voltage = 220 V ; line current excluding field currents = 40 A ; the armature current of motoring machine = 200 A ; field currents 6 A and 7 A. Calculate the efficiency of each of the machines at the given load conditions. The armature resistance of each of the machines is  $0.05 \Omega$ .

**[\eta\_m = 86.58% ; \eta\_g = 86.3%] (Electrical Engg-I, M.S. Univ. Baroda 1980)**

**OBJECTIVE TEST – 31**

- One of the main advantages of Swinburne's test is that it
  - is applicable both to shunt and compound motors
  - needs one running test
  - is very economical and convenient
  - ignores any change in iron loss
- The main disadvantage of Hopkinson's test for finding efficiency of shunt d.c. motors is that it
  - requires full-load power
  - ignores any change in iron loss
  - needs one motor and one generator
  - requires two identical shunt machines
- The most economical method of finding no-load losses of a large d.c. shunt motor is—test.
  - Hopkinson's
  - Swinburne's
  - retardation
  - Field's
- Retardation test on a d.c. shunt motor is used for finding—losses.
  - stray
  - copper
  - friction
  - iron

5. The main thing common between Hopkinson's test and Field's test is that both
- require two electrically-coupled series motors
  - need two similar mechanically-coupled motors
  - use negligible power
  - are regenerative tests
6. The usual test for determining the efficiency of a traction motor is the ..... test.
- Field's
  - retardation
  - Hopkinson's
  - Swinburne's

## QUESTIONS AND ANSWERS ON D.C. MOTORS

**Q. 1. How may the direction of rotation of a d.c. motor be reversed ?**

**Ans.** By reversing either the field current or current through the armature. Usually, reversal of current through the armature is adopted.

**Q. 2. What will happen if both currents are reversed ?**

**Ans.** The motor will run in the original direction.

**Q. 3. What will happen if the field of a d.c. shunt motor is opened ?**

**Ans.** The motor will achieve dangerously high speed and may destroy itself.

**Q. 4. What happens if the direction of current at the terminals of a series motor is reversed ?**

**Ans.** It does not reverse the direction of rotation of motor because current flows through the armature in the same direction as through the field.

**Q. 5. Explain what happens when a d.c. motor is connected across an a.c. supply ?**

**Ans. 1.** Since on a.c. supply, reactance will come into the picture, the a.c. supply will be offered impedance (not resistance) by the armature winding. Consequently, with a.c. supply, current will be much less. The motor will run but it would not carry the same load as it would on d.c. supply.

**2.** There would be more sparking at the brushes.

**3.** Though motor armature is laminated as a rule, the field poles are not. Consequently, eddy currents will cause the motor to heat up and eventually burn on a.c. supply.

**Q. 6. What will happen if a shunt motor is directly connected to the supply line ?**

**Ans.** Small motors up to 1 kW rating may be line-started without any adverse results being produced. High rating motors must be started through a suitable starter in order to avoid the huge starting current which will

(i) damage the motor itself and (ii) badly affect the voltage regulation of the supply line.

**Q. 7. What is the function of interpoles and how are interpole windings connected ?**

**Ans.** Interpoles are small poles placed in between the main poles. Their function is to assist commutation by producing the auxiliary or commutating flux. Consequently, brush sparking is practically eliminated. Interpole windings are connected in series with the armature windings.

**Q. 8. In rewinding the armature of a d.c. motor, progressive connections are changed to retrogressive ones. Will it affect the operation in any way ?**

**Ans.** Yes. Now, the armature will rotate in the opposite direction.

**Q. 9. A d.c. motor fails to start when switched on. What could be the possible reasons and remedies ?**

**Ans.** Any one of the following reasons could be responsible :

1. Open-circuit in controller—should be checked for open starting resistance or open switch or open fuse.
2. Low terminal voltage—should be adjusted to name-plate value.
3. Overload—should be reduced if possible otherwise larger motor should be installed.
4. Excessive friction—bearing lubrication should be checked.

**Q. 10. A d.c. motor is found to stop running after a short period of time. What do you think could be the reasons ? How would you remedy each ?**

**Ans.** Possible causes are as under :

1. Motor not getting enough power—check voltage at motor terminals as well as fuses, clups and overload relay.
2. Weak or no field—in the case of adjustable-speed motors, check if rheostat is correctly set. Also, check field winding for any 'open'. Additionally, look for any loose winding or broken connection.
3. Motor torque insufficient for driving the given load—check line voltage with name-plate voltage. If necessary, use larger motor to match the load.

**Q. 11. What are the likely causes if a d.c. motor is found to run too slow under load ? And the remedy ?**

- Ans.**
1. Supply line voltage too low—remove any excessive resistance in supply line, connections or controller.
  2. Brushes ahead of neutral—set them on neutral.
  3. Overload—reduce it to allowable value or use larger motor.

**Q. 12. Why does a d.c. motor sometime run too fast when under load ? Give different possible causes and their remedies.**

**Ans.** Different possible causes are as under :

1. Weak field—remove any extra resistance in shunt field circuit. Also, check for 'grounds'.
2. Line voltage too high—reduce it to name-plate value.
3. Brushes back of neutral—set them on neutral.

**Q. 13. Under what conditions is sparking produced at the brushes of a d.c. motor ? How would you remedy it ?**

- Ans.**
1. Commutator in bad condition—clean and reset brushes.
  2. commutator either eccentric or rough—grind and true the commutator. Also, undercut mica.
  3. Excessive vibration—balance armature. Make sure that brushes ride freely in holders.
  4. Brush-holding spring broken or sluggish—replace spring and adjust pressure to recommended value.
  5. Motor overloaded—reduce load or install motor of proper rating.
  6. Short-circuit in armature circuit—remove any metallic particles between commutator segments and check for short between adjacent commutator risers. Locate and repair internal armature short if any.

**Q. 14. Sometimes a hissing noise (or brush chatter) is heard to emanate from the commutator end of a running d.c. motor. What could it be due to and how could it be removed ?**

**Ans.** Any one of the following causes could produce brush chatter :

1. Excessive clearance of brush holders—adjust properly
2. Incorrect angle of brushes—adjust to correct value
3. Unsuitable brushes—replace them
4. High mica—undercut it
5. Wrong brush spring pressure—adjust to correct value.

**Q. 15. What are the possible causes of excessive sparking at brushes in a d.c. motor ?**

- Ans.**
1. Poor brush fit on commutator—sand-in the brushes and polish commutator.
  2. Brushes binding in the brush holders—clean holders and brushes and remove any irregularities on surfaces of brush holders or rough spots on brushes.
  3. Excessive or insufficient pressure on brushes—adjust pressure.
  4. Brushes off neutral—set them on neutral.

**Q. 16. Why does a d.c. motor sometime spark on light load ?**

**Ans.** Due to the presence of paint spray, chemical, oil or grease etc. on commutator.

**Q. 17. When is the armature of a d.c. motor likely to get over-heated ?**

- Ans.**
1. When motor is over-loaded.
  2. When it is installed at a place having restricted ventilation.
  3. When armature winding is shorted.

**Q. 18. What causes are responsible for over-heating of commutator in a d.c. motor ?**

**Ans.** It could be due either to the brushes being off neutral or being under excessive spring pressure. Accordingly, brushes should be adjusted properly and the spring pressure should be reduced but not to the point where sparking is introduced.

### Learning Objectives

- Working Principle of Transformer
- Transformer Construction
- Core-type Transformers
- Shell-type Transformers
- E.M.F. Equation of Transformer
- Voltage Transformation Ratio
- Transformer with losses
- Equivalent Resistance

- Transformer with Resistance and Leakage Reactance
- Total Approximate Voltage Drop in Transformer
- Exact Voltage Drop
- Separation of Core Losses
- Short-Circuit or Impedance Test
- Why Transformer Rating in KVA?
- Regulation of a Transformer
- Percentage Resistance, Reactance and Impedance
- Kapp Regulation Diagram
- Sumpner or Back-to-back-Test
- Efficiency of a Transformer
- Auto-transformer

## TRANSFORMER

To overcome losses, the electricity from a generator is passed through a step-up transformer, which increases the voltage. Throughout the distribution system, the voltages are changed using step-down transformers to voltages suitable to the applications at industry and homes.

### 32.1. Working Principle of a Transformer

A transformer is a static (or stationary) piece of apparatus by means of which electric power in one circuit is transformed into electric power of the same frequency in another circuit. It can raise or lower the voltage in a circuit but with a corresponding decrease or increase in current. The physical basis of a transformer is *mutual induction* between two circuits linked by a common magnetic flux. In its simplest form, it consists of two inductive coils which are electrically separated but magnetically linked through a path of low reluctance as shown in Fig. 32.1. The two coils possess high mutual inductance. If one coil is connected to a source of alternating voltage, an alternating flux is set up in the laminated core, most of which is linked with the other coil in which it produces mutually-induced e.m.f. (according to Faraday's Laws of Electromagnetic Induction  $e = Mdi/dt$ ). If the second coil circuit is closed, a current flows in it and so electric energy is transferred (entirely magnetically) from the first coil to the second coil. The first coil, in which electric energy is fed from the a.c. supply mains, is called *primary* winding and the other from which energy is drawn out, is called *secondary* winding. In brief, a transformer is a device that

1. transfers electric power from one circuit to another
2. it does so without a change of frequency
3. it accomplishes this by electromagnetic induction and
4. where the two electric circuits are in mutual inductive influence of each other.

Fig. 32.1

### 32.2. Transformer Construction

The simple elements of a transformer consist of two coils having mutual inductance and a laminated steel core. The two coils are insulated from each other and the steel core. Other necessary parts are : some suitable container for assembled core and windings ; a suitable medium for insulating the core and its windings from its container ; suitable bushings (either of porcelain, oil-filled or capacitor-type) for insulating and bringing out the terminals of windings from the tank.

Fig. 32.2

In all types of transformers,

the core is constructed of transformer sheet steel laminations assembled to provide a continuous magnetic path with a minimum of air-gap included. The steel used is of high silicon content, sometimes heat treated to produce a high permeability and a low hysteresis loss at the

usual operating flux densities. The eddy current loss is minimised by laminating the core, the laminations being insulated from each other by a light coat of core-plate varnish or by an oxide layer on the surface. The thickness of laminations varies from 0.35 mm for a frequency of 50 Hz to 0.5 mm for a frequency of 25 Hz. The core laminations (in the form of strips) are joined as shown in Fig. 32.2. It is seen that the joints in the alternate layers are staggered in order to avoid the presence of narrow gaps right through the cross-section of the core. Such staggered joints are said to be 'imbricated'.

Constructionally, the transformers are of two general types, distinguished from each other merely by the manner in which the primary and secondary coils are placed around the laminated core. The two types are known as (i) core-type and (ii) shell-type. Another recent development is spiral-core or wound-core type, the trade name being spirakore transformer.

In the so-called core type transformers, the windings surround a considerable part of the core whereas in shell-type transformers, the core surrounds a considerable portion of the windings as shown schematically in Fig. 32.3 (a) and (b) respectively.

Fig. 32.3

Fig. 32.4

In the simplified diagram for the core type transformers [Fig. 32.3 (a)], the primary and secondary winding are shown located on the opposite legs (or limbs) of the core, but in actual construction, these are always interleaved to reduce leakage flux. As shown in Fig. 32.4, half the primary and half the secondary winding have been placed side by side or concentrically on each limb, not primary on one limb (or leg) and the secondary on the other.

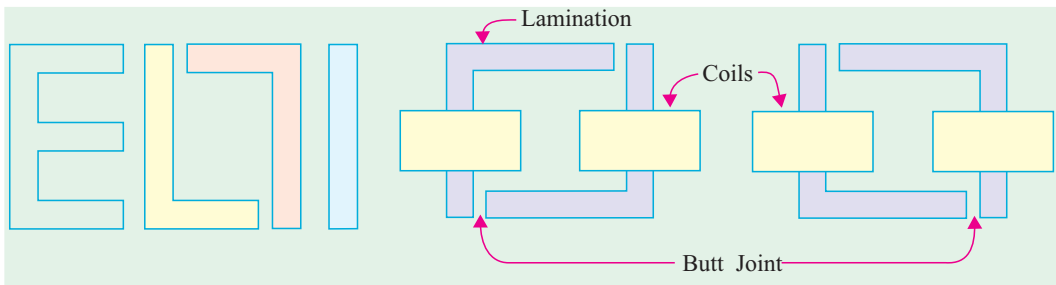

Fig. 32.5

Fig. 32.6

In both core and shell-type transformers, the individual laminations are cut in the form of long strips of L's, E's and I's as shown in Fig. 32.5. The assembly of the complete core for the two types of transformers is shown in Fig. 32.6 and Fig. 32.7.

As said above, in order to avoid high reluctance at the joints where the laminations are butted against each other, the alternate layers are stacked differently to eliminate these joints as shown in Fig. 32.6 and Fig. 32.7.

Fig. 32.7

### 32.3. Core-type Transformers

The coils used are form-wound and are of the cylindrical type. The general form of these coils may be circular or oval or rectangular. In small size core-type transformers, a simple rectangular core is used with cylindrical coils which are either circular or rectangular in form. But for large-size core-type transformers, round

Fig. 32.8 (a)

or circular cylindrical coils are used which are so wound as to fit over a cruciform core section as shown in Fig. 32.8(a). The circular cylindrical coils are used in most of the core-type transformers because of their mechanical strength. Such cylindrical coils are wound in helical layers with the different layers insulated from each other by paper, cloth, micarta board or cooling ducts. Fig. 32.8(c) shows the general arrangement of these coils with respect to the core. Insulating cylinders of fuller board are used to separate the cylindrical windings from the core and from each other. Since the low-voltage (LV) winding is easiest to insulate, it is placed nearest to the core (Fig. 32.8).

Fig. 32.8

Because of laminations and insulation, the net or effective core area is reduced, due allowance for which has to be made (Ex. 32.6). It is found that, in general, the reduction in core sectional area due to the presence of paper, surface oxide etc. is of the order of 10% approximately.

As pointed out above, rectangular cores with rectangular cylindrical coils can be used for small-size core-type transformers as shown in Fig. 32.9 (a) but for large-sized transformers, it becomes wasteful to use rectangular cylindrical coils and so circular cylindrical coils are preferred. For such purposes, square cores may be used as shown in Fig. 32.9 (b) where circles represent the tubular former carrying the coils. Obviously, a considerable amount of useful space is still wasted. A common improvement on square core is to employ cruciform core as in Fig. 32.9 (c) which demands, at least, two sizes of core strips. For very large transformers, further core-stepping is done as in Fig. 32.9 (d) where at least three sizes of core plates are necessary. Core-stepping not only gives high space factor but also results in reduced length of the mean turn and the consequent  $I^2R$  loss. Three stepped core is the one most commonly used although more steps may be used for very large transformers as in Fig. 32.9 (e). From the geometry of Fig. 32.9, it can be shown that maximum gross core section for Fig. 32.9 (b) is  $0.5 d^2$  and for Fig. 32.9 (c) it is  $0.616 d^2$  where  $d$  is the diameter of the cylindrical coil.

Fig. 32.9

### 32.4. Shell-type Transformers

In these case also, the coils are form-wound but are multi-layer disc type usually wound in the form of pancakes. The different layers of such multi-layer discs are insulated from each other by paper. The complete winding consists of stacked discs with insulation space between the coils—the spaces forming horizontal cooling and insulating ducts. A shell-type transformer may have a simple rectangular form as shown in Fig. 32.10 or it may have distributed form as shown in Fig. 32.11.

Fig. 32.10

A very commonly-used shell-type transformer is the one known as Berry Transformer—so called after the name of its designer and is cylindrical in form. The transformer core consists of laminations arranged in groups which radiate out from the centre as shown in section in Fig. 32.12.

It may be pointed out that cores and coils of transformers must be provided with rigid mechanical bracing in order to prevent movement and possible insulation damage. Good bracing reduces vibration and the objectionable noise—a humming sound—during operation.

The spiral-core transformer employs the newest development in core construction. The core is assembled of a continuous strip or ribbon of transformer steel wound in the form of a circular or elliptical cylinder. Such construction allows the core flux to follow the grain of the iron. Cold-rolled steel of high silicon content enables the designer to use considerably higher operating flux densities with lower loss per kg. The use of higher flux density reduces the weight per kVA. Hence, the advantages of such construction are (i) a relatively more rigid core (ii) lesser weight and size per kVA rating (iii) lower iron losses at higher operating flux densities and (iv) lower cost of manufacture.

Fig. 32.11

Fig. 32.12

Transformers are generally housed in tightly-fitted sheet-metal tanks filled with special insulating oil\*. This oil has been highly developed and its function is two-fold. By circulation, it not only keeps the coils reasonably cool, but also provides the transformer with additional insulation not obtainable when the transformer is left in the air.

In cases where a smooth tank surface does not provide sufficient cooling area, the sides of the tank are corrugated or provided with radiators mounted on the sides. Good transformer oil should be absolutely free from alkalies, sulphur and particularly from moisture. The presence of even an extremely small percentage of moisture in the oil is highly detrimental from the insulation viewpoint because it lowers the dielectric strength of the oil considerably. The importance of avoiding moisture in the transformer oil is clear from the fact that even an addition of 8 parts of water in 1,000,000 reduces the insulating quality of the oil to a value generally recognized as below standard. Hence, the tanks are sealed air-tight in smaller units. In the case of large-sized transformers where complete air-tight construction is impossible, chambers known as *breathers* are provided to permit the oil inside the tank to expand and contract as its temperature increases or decreases. The atmospheric moisture is entrapped in these breathers and is not allowed to pass on to the oil. Another thing to avoid in the oil is slogging which is simply the decomposition of oil with long and continued use. Slogging is caused principally by exposure to oxygen during heating and results in the formation of large deposits of dark and heavy matter that eventually clogs the cooling ducts in the transformer.

No other feature in the construction of a transformer is given more attention and care than the insulating materials, because the life on the unit almost solely depends on the quality, durability and handling of these materials. All the insulating materials are selected on the basis of their high quality and ability to preserve high quality even after many years of normal use.

\* Instead of natural mineral oil, now-a-days synthetic insulating fluids known as ASKARELS (trade name) are used. They are non-inflammable and, under the influence of an electric arc, do not decompose to produce inflammable gases. One such fluid commercially known as PYROCLOR is being extensively used because it possesses remarkable stability as a dielectric and even after long service shows no deterioration through slogging, oxidation, acid or moisture formation. Unlike mineral oil, it shows no rapid burning.

All the transformer leads are brought out of their cases through suitable bushings. There are many designs of these, their size and construction depending on the voltage of the leads. For moderate voltages, porcelain bushings are used to insulate the leads as they come out through the tank. In general, they look almost like the insulators used on the transmission lines. In high voltage installations, oil-filled or capacitor-type bushings are employed.

The choice of core or shell-type construction is usually determined by cost, because similar characteristics can be obtained with both types. For very high-voltage transformers or for multiwinding design, shell-type construction is preferred by many manufacturers. In this type, usually the mean length of coil turn is longer than in a comparable core-type design. Both core and shell forms are used and the selection is decided by many factors such as voltage rating, kVA rating, weight, insulation stress, heat distribution etc.

Another means of classifying the transformers is according to the type of cooling employed. The following types are in common use :

- (a) *oil-filled self-cooled*      (b) *oil-filled water-cooled*      (c) *air-blast type*

Small and medium size distribution transformers—so called because of their use on distribution systems as distinguished from line transmission—are of type (a). The assembled windings and cores of such transformers are mounted in a welded, oil-tight steel tank provided with steel cover. After putting the core at its proper place, the tank is filled with purified, high quality insulating oil. The oil serves to convey the heat from the core and the windings to the case from where it is radiated out to the surroundings. For small size, the tanks are usually smooth-surfaced, but for larger sizes, the cases are frequently corrugated or fluted to get greater heat radiation area without increasing the cubical capacity of the tank. Still larger sizes are provided with radiators or pipes.

Construction of very large self-cooled transformers is expensive, a more economical form of construction for such large transformers is provided in the oil-immersed, water-cooled type. As before, the windings and the core are immersed in the oil, but there is mounted near the surface of oil, a cooling coil through which cold water is kept circulating. The heat is carried away by this water. The largest transformers such as those used with high-voltage transmission lines, are constructed in this manner.

Oil-filled transformers are built for outdoor duty and as these require no housing other than their own, a great saving is thereby effected. These transformers require only periodic inspection.

For voltages below 25,000 V, transformers can be built for cooling by means of an air-blast. The transformer is not immersed in oil, but is housed in a thin sheet-metal box open at both ends through which air is blown from the bottom to the top by means of a fan or blower.

### 32.5. Elementary Theory of an Ideal Transformer

An ideal transformer is one which has no losses *i.e.* its windings have no ohmic resistance, there is no magnetic leakage and hence which has no  $I^2R$  and core losses. In other words, an ideal transformer consists of two purely inductive coils wound on a loss-free core. It may, however, be noted *that it is impossible to realize such a transformer in practice, yet for convenience, we will start with such a transformer and step by step approach an actual transformer.*

Fig. 32.13

Consider an ideal transformer [Fig. 32.13 (a)] whose secondary is open and whose primary is connected to sinusoidal alternating voltage  $V_1$ . This potential difference causes an alternating current to flow in the primary. Since the primary coil is purely inductive and there is no output (secondary being open) the primary draws the magnetising current  $I_\mu$  only. The function of this current is merely to magnetise the core, it is small in magnitude and lags  $V_1$  by  $90^\circ$ . This alternating current  $I_\mu$  produces an alternating flux  $\phi$  which is, at all times, proportional to the current (assuming permeability of the magnetic circuit to be constant) and, hence, is in phase with it. This changing flux is linked both with the primary and the secondary windings. Therefore, it produces self-induced e.m.f. in the primary. This *self-induced* e.m.f.  $E_1$  is, at every instant, equal to and in opposition to  $V_1$ . It is also known as counter e.m.f. or back e.m.f. of the primary.

Similarly, there is produced in the secondary an induced e.m.f.  $E_2$  which is known as *mutually* induced e.m.f. This e.m.f. is antiphase with  $V_1$  and its magnitude is proportional to the rate of change of flux and the number of secondary turns.

The instantaneous values of applied voltage, induced e.m.fs, flux and magnetising current are shown by sinusoidal waves in Fig. 32.13 (b). Fig. 32.13 (c) shows the vectorial representation of the effective values of the above quantities.

### 32.6. E.M.F. Equation of a Transformer

- Let  $N_1$  = No. of turns in primary
- $N_2$  = No. of turns in secondary
- $\Phi_m$  = Maximum flux in core in webers  
 $= B_m \times A$
- $f$  = Frequency of a.c. input in Hz

As shown in Fig. 32.14, flux increases from its zero value to maximum value  $\Phi_m$  in one quarter of the cycle *i.e.* in  $1/4f$  second.

$$\therefore \text{Average rate of change of flux} = \frac{\Phi_m}{1/4f}$$

$$= 4f\Phi_m \text{ Wb/s or volt}$$

Now, rate of change of flux per turn means induced e.m.f. in volts.

$$\therefore \text{Average e.m.f./turn} = 4f\Phi_m \text{ volt}$$

If flux  $\Phi$  varies *sinusoidally*, then r.m.s. value of induced e.m.f. is obtained by multiplying the average value with form factor.

$$\text{Form factor} = \frac{\text{r.m.s. value}}{\text{average value}} = 1.11$$

$$\therefore \text{r.m.s. value of e.m.f./turn} = 1.11 \times 4f\Phi_m = 4.44f\Phi_m \text{ volt}$$

Now, r.m.s. value of the induced e.m.f. in the whole of primary winding

$$= (\text{induced e.m.f./turn}) \times \text{No. of primary turns}$$

$$E_1 = 4.44fN_1\Phi_m = 4.44fN_1B_mA \quad \dots(i)$$

Fig. 32.14

Similarly, r.m.s. value of the e.m.f. induced in secondary is,

$$E_2 = 4.44 f N_2 \Phi_m = 4.44 f N_2 B_m A \quad \dots (ii)$$

It is seen from (i) and (ii) that  $E_1/N_1 = E_2/N_2 = 4.44 f \Phi_m$ . It means that e.m.f./turn is the same in both the primary and secondary windings.

In an ideal transformer on no-load,  $V_1 = E_1$  and  $E_2 = V_2$  where  $V_2$  is the terminal voltage (Fig. 32.15).

### 32.7 Voltage Transformation Ratio (K)

From equations (i) and (ii), we get

$$\frac{E_2}{E_1} = \frac{N_2}{N_1} = K$$

This constant  $K$  is known as voltage transformation ratio.

(i) If  $N_2 > N_1$  i.e.  $K > 1$ , then transformer is called **step-up** transformer.

(ii) If  $N_2 < N_1$  i.e.  $K < 1$ , then transformer is known as **step-down** transformer.

Again, for an ideal transformer, input VA = output VA.

$$V_1 I_1 = V_2 I_2 \text{ or } \frac{I_2}{I_1} = \frac{V_1}{V_2} = \frac{1}{K}$$

Hence, currents are in the inverse ratio of the (voltage) transformation ratio.

Fig. 32.15

**Example 32.1.** The maximum flux density in the core of a 250/3000-volts, 50-Hz single-phase transformer is  $1.2 \text{ Wb/m}^2$ . If the e.m.f. per turn is 8 volt, determine

- (i) primary and secondary turns (ii) area of the core.

(Electrical Engg.-I, Nagpur Univ. 1991)

**Solution. (i)**

$$E_1 = N_1 \times \text{e.m.f. induced/turn}$$

$$N_1 = 250/8 = 32; N_2 = 3000/8 = 375$$

(ii) We may use

$$E_2 = -4.44 f N_2 B_m A$$

$$\therefore 3000 = 4.44 \times 50 \times 375 \times 1.2 \times A; A = 0.03\text{m}^2.$$

**Example 32.2.** The core of a 100-kVA, 11000/550 V, 50-Hz, 1-ph, core type transformer has a cross-section of  $20 \text{ cm} \times 20 \text{ cm}$ . Find (i) the number of H.V. and L.V. turns per phase and (ii) the e.m.f. per turn if the maximum core density is not to exceed 1.3 Tesla. Assume a stacking factor of 0.9.

What will happen if its primary voltage is increased by 10% on no-load ?

(Elect. Machines, A.M.I.E. Sec. B, 1991)

**Solution. (i)**

$$B_m = 1.3 \text{ T}, A = (0.2 \times 0.2) \times 0.9 = 0.036 \text{ m}^2$$

$$\therefore 11,000 = 4.44 \times 50 \times N_1 \times 1.3 \times 0.036, N_1 = 1060$$

$$550 = 4.44 \times 50 \times N_2 \times 1.3 \times 0.036; N_2 = 53$$

or,  $N_2 = K N_1 = (550/11,000) \times 1060 = 53$

(ii) e.m.f./turn =  $11,000/1060 = 10.4 \text{ V}$  or  $550/53 = 10.4 \text{ V}$

Keeping supply frequency constant, if primary voltage is increased by 10%, magnetising current will increase by much more than 10%. However, due to saturation, flux density will increase only marginally and so will the eddy current and hysteresis losses.

**Example 32.3.** A single-phase transformer has 400 primary and 1000 secondary turns. The net cross-sectional area of the core is  $60 \text{ cm}^2$ . If the primary winding be connected to a 50-Hz supply at 520 V, calculate (i) the peak value of flux density in the core (ii) the voltage induced in the secondary winding.

(Elect. Engg.-I, Pune Univ. 1989)

**Solution.**

$$K = N_2/N_1 = 1000/400 = 2.5$$

$$(i) \quad E_2/E_1 = K \quad \therefore \quad E_2 = KE_1 = 2.5 \times 520 = \mathbf{1300 \text{ V}}$$

$$(ii) \quad E_1 = 4.44 f N_1 B_m A$$

$$\text{or} \quad 520 = 4.44 \times 50 \times 400 \times B_m \times (60 \times 10^{-4}) \quad \therefore \quad B_m = \mathbf{0.976 \text{ Wb/m}^2}$$

**Example 32.4.** A 25-kVA transformer has 500 turns on the primary and 50 turns on the secondary winding. The primary is connected to 3000-V, 50-Hz supply. Find the full-load primary and secondary currents, the secondary e.m.f. and the maximum flux in the core. Neglect leakage drops and no-load primary current. **(Elect. & Electronic Engg., Madras Univ. 1985)**

**Solution.**

$$K = N_2/N_1 = 50/500 = 1/10$$

$$\text{Now, full-load} \quad I_1 = 25,000/3000 = \mathbf{8.33 \text{ A}}. \quad \text{F.L. } I_2 = I_1/K = 10 \times 8.33 = \mathbf{83.3 \text{ A}}$$

$$\text{e.m.f. per turn on primary side} = 3000/500 = 6 \text{ V}$$

$$\therefore \quad \text{secondary e.m.f.} = 6 \times 50 = \mathbf{300 \text{ V}} \quad (\text{or } E_2 = KE_1 = 3000 \times 1/10 = 300 \text{ V})$$

$$\text{Also,} \quad E_1 = 4.44 f N_1 \Phi_m; \quad 3000 = 4.44 \times 50 \times 500 \times \Phi_m \quad \therefore \quad \Phi_m = \mathbf{27 \text{ mWb}}$$

**Example 32.5.** The core of a three phase, 50 Hz, 11000/550 V delta/star, 300 kVA, core-type transformer operates with a flux of 0.05 Wb. Find

(i) number of H.V. and L.V. turns per phase. (ii) e.m.f. per turn

(iii) full load H.V. and L.V. phase-currents. **(Bharathithasan Univ. April 1997)**

**Solution.** Maximum value of flux has been given as 0.05 Wb.

$$(ii) \quad \text{e.m.f. per turn} = 4.44 f \phi_m \\ = 4.44 \times 50 \times 0.05 = 11.1 \text{ volts}$$

(i) Calculations for number of turns on two sides :

Voltage per phase on delta-connected primary winding = 11000 volts

Voltage per phase on star-connected secondary winding =  $550/1.732 = 317.5$  volts

$$T_1 = \text{number of turns on primary, per phase} \\ = \text{voltage per phase/e.m.f. per turn} \\ = 11000/11.1 = 991$$

$$T_2 = \text{number of turns on secondary, per phase} \\ = \text{voltage per phase/e.m.f. per turn} \\ = 317.5/11.1 = 28.6$$

**Note :** (i) Generally, Low-voltage-turns are calculated first, the figure is rounded off to next higher even integer. In this case, it will be 30. Then, number of turns on primary side is calculated by turns-ratio.

$$\text{In this case,} \quad T_1 = T_2 (V_1/V_2) = 30 \times 11000/317.5 = 1040$$

This, however, reduces the flux and results into less saturation. This, in fact, is an elementary aspect in Design-calculations for transformers. (Explanation is added here only to overcome a doubt whether a fraction is acceptable as a number of L.V. turns).

(ii) Full load H.V. and L.V. phase currents :

$$\text{Output per phase} = (300/3) = 100 \text{ kVA}$$

$$\text{H.V. phase-current} = \frac{100 \times 1000}{11,000} = 9.1 \text{ Amp}$$

$$\text{L.V. phase-current} = (100 \times 1000/317.5) = 315 \text{ Amp}$$

**Example 32.6.** A single phase transformer has 500 turns in the primary and 1200 turns in the secondary. The cross-sectional area of the core is 80 sq. cm. If the primary winding is connected to a 50 Hz supply at 500 V, calculate (i) Peak flux-density, and (ii) Voltage induced in the secondary.

**(Bharathiar University November 1997)**

**Solution.** From the e.m.f. equation for transformer,

$$500 = 4.44 \times 50 \times \phi_m \times 500$$

$$\phi_m = 1/222 \text{ Wb}$$

(i) Peak flux density,  $B_m = \phi_m / (80 \times 10^{-4}) = 0.563 \text{ wb/m}^2$

(ii) Voltage induced in secondary is obtained from transformation ratio or turns ratio

$$\frac{V_2}{V_1} = \frac{N_2}{N_1}$$

or  $V_2 = 500 \times 1200/500 = 1200 \text{ volts}$

**Example 32.7.** A 25 kVA, single-phase transformer has 250 turns on the primary and 40 turns on the secondary winding. The primary is connected to 1500-volt, 50 Hz mains. Calculate (i) Primary and Secondary currents on full-load, (ii) Secondary e.m.f., (iii) maximum flux in the core.

(Bharathiar Univ. April 1998)

**Solution. (i)** If  $V_2 =$  Secondary voltage rating, = secondary e.m.f.,

$$\frac{V_2}{1500} = \frac{40}{250}, \text{ giving } V_2 = 240 \text{ volts}$$

(ii) Primary current =  $25000/1500 = 16.67 \text{ amp}$

Secondary current =  $25000/240 = 104.2 \text{ amp}$

(iii) If  $\phi_m$  is the maximum core-flux in Wb,

$$1500 = 4.44 \times 50 \times \phi_m \times 250, \text{ giving } \phi_m = 0.027 \text{ Wb or } 27 \text{ mWb}$$

**Example 32.8.** A single-phase, 50 Hz, core-type transformer has square cores of 20 cm side. Permissible maximum flux-density is  $1 \text{ Wb/m}^2$ . Calculate the number of turns per Limb on the High and Low-voltage sides for a 3000/220 V ratio. (Manonmaniam Sundaranar Univ. April 1998)

**Solution.** E.M.F. equation gives the number of turns required on the two sides. We shall first calculate the L.V.-turns, round the figure off to the next higher even number, so that given maximum flux density is not exceeded. With the corrected number of L.V. turns, calculate H.V.-turns by transformation ratio. Further, there are two Limbs. Each Limb accommodates half-L.V. and half H.V. winding from the view-point of reducing leakage reactance.

Starting with calculation for L.V. turns,  $T_2$ ,

$$4.44 \times 50 \times [(20 \times 20 \times 10^{-4}) \times 1] \times T_2 = 220$$

$$T_2 = 220/8.88 = 24.77$$

Select  $T_2 = 26$

$$T_1/T_2 = V_1/V_2$$

$$T_1 = 26 \times 3000/220 = 354, \text{ selecting the nearest even integer.}$$

Number of H.V. turns on each Limb = 177

Number of L.V. turns on each Limb = 13

## 32.8. Transformer with Losses but no Magnetic Leakage

We will consider two cases (i) when such a transformer is on no load and (ii) when it is loaded.

## 32.9. Transformer on No-load

In the above discussion, we assumed an ideal transformer *i.e.* one in which there were no core losses and copper losses. But practical conditions require that certain modifications be made in the foregoing

theory. When an *actual* transformer is put on load, there is iron loss in the core and copper loss in the windings (both primary and secondary) and these losses are not entirely negligible.

Even when the transformer is on no-load, the primary input current is not wholly reactive. The primary input current under no-load conditions has to supply (i) iron losses in the core *i.e.* hysteresis loss and eddy current loss and (ii) a very small amount of copper loss in primary (there being no Cu loss in secondary as it is open). Hence, the no-load primary input current  $I_0$  is not at  $90^\circ$  behind  $V_1$  but lags it by an angle  $\phi_0 < 90^\circ$ . No-load input power

$$W_0 = V_1 I_0 \cos \phi_0$$

where  $\cos \phi_0$  is primary power factor under no-load conditions. No-load condition of an actual transformer is shown vectorially in Fig. 32.16.

As seen from Fig. 32.16, primary current  $I_0$  has two components :

(i) One in phase with  $V_1$ . This is known as *active* or *working* or *iron* loss component  $I_w$  because it mainly supplies the iron loss plus small quantity of primary Cu loss.

$$I_w = I_0 \cos \phi_0$$

(ii) The other component is in quadrature with  $V_1$  and is known as *magnetising* component  $I_\mu$  because its function is to sustain the alternating flux in the core. It is wattless.

$$I_\mu = I_0 \sin \phi_0$$

Obviously,  $I_0$  is the vector sum of  $I_w$  and  $I_\mu$ , hence  $I_0 = \sqrt{I_\mu^2 + I_w^2}$ .

The following points should be noted carefully :

1. The no-load primary current  $I_0$  is very small as compared to the full-load primary current. It is about 1 per cent of the full-load current.
2. Owing to the fact that the permeability of the core varies with the instantaneous value of the exciting or magnetising current, the wave of the exciting or magnetising current is not truly sinusoidal. As such it should not be represented by a vector because only sinusoidally varying quantities are represented by rotating vectors. But, in practice, it makes no appreciable difference.
3. As  $I_0$  is very small, the no-load primary Cu loss is negligibly small which means *that no-load primary input is practically equal to the iron loss in the transformer.*
4. As it is principally the core-loss which is responsible for shift in the current vector, angle  $\phi_0$  is known as *hysteresis angle of advance.*

**Example 32.9.** (a) A 2,200/200-V transformer draws a no-load primary current of 0.6 A and absorbs 400 watts. Find the magnetising and iron loss currents.

(b) A 2,200/250-V transformer takes 0.5 A at a p.f. of 0.3 on open circuit. Find magnetising and working components of no-load primary current.

**Solution.** (a) Iron-loss current

$$= \frac{\text{no-load input in watts}}{\text{primary voltage}} = \frac{400}{2,200} = \mathbf{0.182 \text{ A}}$$

Now 
$$I_0^2 = I_w^2 + I_\mu^2$$

Magnetising component 
$$I_\mu = \sqrt{(0.6^2 - 0.182^2)} = \mathbf{0.572 \text{ A}}$$

The two components are shown in Fig. 29.15.

Fig. 32.16

$$(b) \quad I_0 = 0.5 \text{ A}, \cos \phi_0 = 0.3 \therefore I_w = I_0 \cos \phi_0 = 0.5 \times 0.3 = 0.15 \text{ A}$$

$$I_\mu = \sqrt{0.5^2 - 0.15^2} = 0.476 \text{ A}$$

**Example 32.10.** A single-phase transformer has 500 turns on the primary and 40 turns on the secondary winding. The mean length of the magnetic path in the iron core is 150 cm and the joints are equivalent to an air-gap of 0.1 mm. When a p.d. of 3,000 V is applied to the primary, maximum flux density is  $1.2 \text{ Wb/m}^2$ . Calculate (a) the cross-sectional area of the core (b) no-load secondary voltage (c) the no-load current drawn by the primary (d) power factor on no-load. Given that AT/cm for a flux density of  $1.2 \text{ Wb/m}^2$  in iron to be 5, the corresponding iron loss to be 2 watt/kg at 50 Hz and the density of iron as  $7.8 \text{ gram/cm}^3$ .

**Solution.** (a)  $3,000 = 4.44 \times 50 \times 500 \times 1.2 \times A \therefore A = 0.0225 \text{ m}^2 = 225 \text{ cm}^2$

This is the net cross-sectional area. However, the gross area would be about 10% more to allow for the insulation between laminations.

(b)  $K = N_2/N_1 = 40/500 = 4/50$   
 $\therefore$  N.L. secondary voltage =  $KE_1 = (4/50) \times 3000 = 240 \text{ V}$

(c) AT per cm = 5  $\therefore$  AT for iron core =  $150 \times 5 = 750$

$$AT \text{ for air-gap} = Hl = \frac{B}{\mu_0} \times l = \frac{1.2}{4\pi \times 10^{-7}} \times 0.0001 = 95.5$$

Total AT for given  $B_{max} = 750 + 95.5 = 845.5$

Max. value of magnetising current drawn by primary =  $845.5/500 = 1.691 \text{ A}$

Assuming this current to be sinusoidal, its r.m.s. value is  $I_\mu = 1.691/\sqrt{2} = 1.196 \text{ A}$

Volume of iron = length  $\times$  area =  $150 \times 225 = 33,750 \text{ cm}^3$

Density =  $7.8 \text{ gram/cm}^3 \therefore$  Mass of iron =  $33,750 \times 7.8/1000 = 263.25 \text{ kg}$

Total iron loss =  $263.25 \times 2 = 526.5 \text{ W}$

Iron loss component of no-load primary current  $I_0$  is  $I_w = 526.5/3000 = 0.176 \text{ A}$

$$I_0 = \sqrt{I_\mu^2 + I_w^2} = \sqrt{1.196^2 + 0.176^2} = 0.208 \text{ A}$$

(d) Power factor,  $\cos \phi_0 = I_w/I_0 = 0.176/1.208 = 0.1457$

**Example 32.11.** A single-phase transformer has 1000 turns on the primary and 200 turns on the secondary. The no load current is 3 amp. at a p.f. of 0.2 lagging. Calculate the primary current and power-factor when the secondary current is 280 Amp at a p.f. of 0.80 lagging.

(Nagpur University, November 1997)

**Solution.**  $V_2$  is taken as reference.  $\cos^{-1} 0.80 = 36.87^\circ$

$$I_2 = 280 \angle -36.87^\circ \text{ amp}$$

$$I'_2 = (280/5) \angle -36.87^\circ \text{ amp}$$

$$\phi = \cos^{-1} 0.20 = 78.5^\circ, \sin \phi = 0.98$$

$$I_1 = I_0 + I'_2 = 3(0.20 - j0.98) + 56(0.80 - j0.60)$$

$$= 0.6 - j2.94 + 44.8 - j33.6$$

$$= 45.4 - j2.94 + 44.8 - j33.6$$

$$= 45.4 - j36.54 = 58.3 \angle 38.86^\circ$$

Thus  $I$  lags behind the supply voltage by an angle of  $38.86^\circ$ .

## Tutorial Problems 32.1

1. The number of turns on the primary and secondary windings of a 1- $\phi$  transformer are 350 and 35 respectively. If the primary is connected to a 2.2 kV, 50-Hz supply, determine the secondary voltage on no-load. [220 V] (Elect. Engg.-II, Kerala Univ. 1980)
2. A 3000/200-V, 50-Hz, 1-phase transformer is built on a core having an effective cross-sectional area of 150 cm<sup>2</sup> and has 80 turns in the low-voltage winding. Calculate
  - (a) the value of the maximum flux density in the core
  - (b) the number of turns in the high-voltage winding. [(a) 0.75 Wb/m<sup>2</sup> (b) 1200]
3. A 3,300/230-V, 50-Hz, 1-phase transformer is to be worked at a maximum flux density of 1.2 Wb/m<sup>2</sup> in the core. The effective cross-sectional area of the transformer core is 150 cm<sup>2</sup>. Calculate suitable values of primary and secondary turns. [830; 58]
4. A 40-kVA, 3,300/240-V, 50 Hz, 1-phase transformer has 660 turns on the primary. Determine
  - (a) the number of turns on the secondary
  - (b) the maximum value of flux in the core
  - (c) the approximate value of primary and secondary full-load currents.
 Internal drops in the windings are to be ignored. [(a) 48 (b) 22.5 mWb (c) 12.1 A; 166.7 A]
5. A double-wound, 1-phase transformer is required to step down from 1900 V to 240 V, 50-Hz. It is to have 1.5 V per turn. Calculate the required number of turns on the primary and secondary windings respectively.
 

The peak value of flux density is required to be not more than 1.2 Wb/m<sup>2</sup>. Calculate the required cross-sectional area of the steel core. If the output is 10 kVA, calculate the secondary current.

[1,267; 160; 56.4 cm<sup>2</sup>; 41.75 A]
6. The no-load voltage ratio in a 1-phase, 50-Hz, core-type transformer is 1,200/440. Find the number of turns in each winding if the maximum flux is to be 0.075 Wb. [24 and 74 turns]
7. A 1-phase transformer has 500 primary and 1200 secondary turns. The net cross-sectional area of the core is 75 cm<sup>2</sup>. If the primary winding be connected to a 400-V, 50 Hz supply, calculate.
  - (i) the peak value of flux density in the core and (ii) voltage induced in the secondary winding. [0.48 Wb/m<sup>2</sup>; 60 V]
8. A 10-kVA, 1-phase transformer has a turn ratio of 300/23. The primary is connected to a 1500-V, 60 Hz supply. Find the secondary volts on open-circuit and the approximate values of the currents in the two windings on full-load. Find also the maximum value of the flux. [115 V; 6.67 A; 87 A; 11.75 mWb]
9. A 100-kVA, 3300/400-V, 50 Hz, 1 phase transformer has 110 turns on the secondary. Calculate the approximate values of the primary and secondary full-load currents, the maximum value of flux in the core and the number of primary turns.
 

How does the core flux vary with load ? [30.3 A; 250 A; 16.4 mWb; 907]
10. The no-load current of a transformer is 5.0 A at 0.3 power factor when supplied at 230-V, 50-Hz. The number of turns on the primary winding is 200. Calculate (i) the maximum value of flux in the core (ii) the core loss (iii) the magnetising current. [5.18 mWb; 345 W; 4.77 A]
11. The no-load current of a transformer is 15 at a power factor of 0.2 when connected to a 460-V, 50-Hz supply. If the primary winding has 550 turns, calculate
  - (a) the magnetising component of no-load current
  - (b) the iron loss
  - (c) the maximum value of the flux in the core. [(a) 14.7 A (b) 1,380 W (c) 3.77 mWb]
12. The no-load current of a transformer is 4.0 A at 0.25 p.f. when supplied at 250-V, 50 Hz. The number of turns on the primary winding is 200. Calculate
  - (i) the r.m.s. value of the flux in the core (assume sinusoidal flux)
  - (ii) the core loss
  - (iii) the magnetising current. [(i) 3.96 mWb (ii) 250 W (iii) 3.87 A]

13. The following data apply to a single-phase transformer:  
 output : 100 kVA, secondary voltage; 400 V; Primary turns: 200; secondary turns: 40; Neglecting the losses, calculate: (i) the primary applied voltage (ii) the normal primary and secondary currents (iii) the secondary current, when the load is 25 kW at 0.8 power factor.  
 (Rajiv Gandhi Technical University, Bhopal 2000) [(i) 2000 V, (ii) 50 amp, (iii) 78.125 amp]

### 32.10. Transformer on Load

When the secondary is loaded, the secondary current  $I_2$  is set up. The magnitude and phase of  $I_2$  with respect to  $V_2$  is determined by the characteristics of the load. Current  $I_2$  is in phase with  $V_2$  if load is non-inductive, it lags if load is inductive and it leads if load is capacitive.

The secondary current sets up its own m.m.f. ( $=N_2I_2$ ) and hence its own flux  $\Phi_2$  which is in opposition to the main primary flux  $\Phi$  which is due to  $I_0$ . The secondary ampere-turns  $N_2 I_2$  are known as **demagnetising** amp-turns. The opposing secondary flux  $\Phi_2$  weakens the primary flux  $\Phi$  momentarily, hence primary back e.m.f.  $E_1$  tends to be reduced. For a moment  $V_1$  gains the upper hand over  $E_1$  and hence causes more current to flow in primary.

Let the additional primary current be  $I_2'$ . It is known as **load component of primary current**. This current is antiphase with  $I_2$ . The additional primary m.m.f.  $N_1 I_2'$  sets up its own flux  $\Phi_2'$  which is in opposition to  $\Phi_2$  (but is in the same direction as  $\Phi$ ) and is equal to it in magnitude. Hence, the two cancel each other out. So, we find that the magnetic effects of secondary current  $I_2$  are immediately neutralized by the additional primary current  $I_2'$  which is brought into existence exactly at the same instant as  $I_2$ . The whole process is illustrated in Fig. 32.17.

Fig. 32.17

Hence, whatever the load conditions, **the net flux passing through the core is approximately the same as at no-load**. An important deduction is that due to the constancy of core flux at all loads, **the core loss is also practically the same under all load conditions**.

As  $\Phi_2 = \Phi_2' \therefore N_2 I_2 = N_1 I_2' \therefore I_2' = \frac{N_2}{N_1} \times I_2 = K I_2$

Hence, when transformer is on load, the primary winding has two currents in it; one is  $I_0$  and the other is  $I_2'$  which is anti-phase with  $I_2$  and  $K$  times in magnitude. **The total primary current is the vector sum of  $I_0$  and  $I_2'$ .**

Fig. 32.18

In Fig. 32.18 are shown the vector diagrams for a load transformer when load is non-inductive and when it is inductive (a similar diagram could be drawn for capacitive load). Voltage transformation ratio of unity is assumed so that primary vectors are equal to the secondary vectors. With reference to Fig. 32.18 (a),  $I_2$  is secondary current in phase with  $E_2$  (strictly speaking it should be  $V_2$ ). It causes primary current  $I_2'$  which is anti-phase with it and equal to it in magnitude ( $\because K = 1$ ). Total primary current  $I_1$  is the vector sum of  $I_0$  and  $I_2'$  and lags behind  $V_1$  by an angle  $\phi_1$ .

In Fig. 32.18 (b) vectors are drawn for an inductive load. Here  $I_2$  lags  $E_2$  (actually  $V_2$ ) by  $\phi_2$ . Current  $I_2'$  is again antiphase with  $I_2$  and equal to it in magnitude. As before,  $I_1$  is the vector sum of  $I_2'$  and  $I_0$  and lags behind  $V_1$  by  $\phi_1$ .

It will be observed that  $\phi_1$  is slightly greater than  $\phi_2$ . But if we neglect  $I_0$  as compared to  $I_2'$  as in Fig. 32.18 (c), then  $\phi_1 = \phi_2$ . Moreover, under this assumption

$$N_1 I_2' = N_2 I_1 = N_1 I_2 \quad \therefore \quad \frac{I_2'}{I_2} = \frac{I_1}{I_2} = \frac{N_2}{N_1} = K$$

It shows that under full-load conditions, the ratio of primary and secondary currents is constant. This important relationship is made the basis of current transformer—a transformer which is used with a low-range ammeter for measuring currents in circuits where the direct connection of the ammeter is impracticable.

**Example 32.12.** A single-phase transformer with a ratio of 440/110-V takes a no-load current of 5A at 0.2 power factor lagging. If the secondary supplies a current of 120 A at a p.f. of 0.8 lagging, estimate the current taken by the primary. (Elect. Engg. Punjab Univ. 1991)

**Solution.**  $\cos \phi_2 = 0.8, \phi_2 = \cos^{-1}(0.8) = 36^\circ 54'$   
 $\cos \phi_0 = 0.2 \quad \therefore \quad \phi_0 = \cos^{-1}(0.2) = 78^\circ 30'$   
 Now  $K = V_2/V_1 = 110/440 = 1/4$   
 $\therefore \quad I_2' = K I_2 = 120 \times 1/4 = 30 \text{ A}$   
 $I_0 = 5 \text{ A.}$

Angle between  $I_0$  and  $I_2'$   
 $= 78^\circ 30' - 36^\circ 54' = 41^\circ 36'$

Using parallelogram law of vectors (Fig. 32.19) we get

$$I_1 = \sqrt{(5^2 + 30^2 + 2 \times 5 \times 30 \times \cos 41^\circ 36')} = 34.45 \text{ A}$$

The resultant current could also have been found by resolving  $I_2'$  and  $I_0$  into their X and Y-components.

**Example 32.13.** A transformer has a primary winding of 800 turns and a secondary winding of 200 turns. When the load current on the secondary is 80 A at 0.8 power factor lagging, the primary current is 25 A at 0.707 power factor lagging. Determine graphically or otherwise the no-load current of the transformer and its phase with respect to the voltage.

**Solution.** Here  $K = 200/800 = 1/4; I_2' = 80 \times 1/4 = 20 \text{ A}$   
 $\phi_2 = \cos^{-1}(0.8) = 36.9^\circ; \phi_1 = \cos^{-1}(0.707) = 45^\circ$

As seen from Fig. 32.20,  $I_1$  is the vector sum of  $I_0$  and  $I_2'$ . Let  $I_0$  lag behind  $V_1$  by an angle  $\phi_0$ .

$$I_0 \cos \phi_0 + 20 \cos 36.9^\circ = 25 \cos 45^\circ$$

Fig. 32.19

Fig. 32.20

$$\begin{aligned} \therefore I_0 \cos \phi_2 &= 25 \times 0.707 - 20 \times 0.8 \\ &= 1.675 \text{ A} \\ I_0 \sin \phi_0 + 20 \sin 36.9^\circ &= 25 \sin 45^\circ \\ \therefore I_0 \sin \phi_0 &= 25 \times 0.707 - 20 \times 0.6 \\ &= 5.675 \text{ A} \\ \therefore \tan \phi_0 &= 5.675/1.675 = 3.388 \\ \therefore \phi_0 &= 73.3^\circ \\ \text{Now, } I_0 \sin \phi_0 &= 5.675 \\ \therefore I_0 &= 5.675/\sin 73.3^\circ = 5.93 \text{ A} \end{aligned}$$

**Example 32.14.** A single phase transformer takes 10 A on no load at p.f. of 0.2 lagging. The turns ratio is 4 : 1 (step down). If the load on the secondary is 200 A at a p.f. of 0.85 lagging. Find the primary current and power factor.

Neglect the voltage-drop in the winding.

(Nagpur University November 1999)

**Solution.** Secondary load of 200 A, 0.85 lag is reflected as 50 A, 0.85 lag in terms of the primary equivalent current.

$$\begin{aligned} I_0 &= 10 \angle -\phi_0, \text{ where } \phi_0 = \cos^{-1} 0.20 = 78.5^\circ \text{ lagging} \\ &= 2 - j9.8 \text{ amp} \end{aligned}$$

$$\begin{aligned} I_2' &= 50 \angle -\phi_L \text{ where } \phi_L = \cos^{-1} 0.85 = 31.8^\circ, \text{ lagging} \\ I_2' &= 42.5 - j26.35 \end{aligned}$$

Hence primary current  $I_1$

$$\begin{aligned} &= I_0 + I_2' \\ &= 2 - j9.8 + 42.5 - j26.35 \\ &= 44.5 - j36.15 \end{aligned}$$

$$|I_1| = 57.333 \text{ amp, } \phi = 0.776 \text{ Lag.}$$

$$\phi = \cos^{-1} \frac{44.5}{57.333} = 39.10^\circ \text{ lagging}$$

Fig. 32.21

The phasor diagram is shown in Fig. 32.21.

### Tutorial Problems 32.2

- The primary of a certain transformer takes 1 A at a power factor of 0.4 when it is connected across a 200-V, 50-Hz supply and the secondary is on open circuit. The number of turns on the primary is twice that on the secondary. A load taking 50 A at a lagging power factor of 0.8 is now connected across the secondary. What is now the value of primary current ? [25.9 A]
- The number of turns on the primary and secondary windings of a single-phase transformer are 350 and 38 respectively. If the primary winding is connected to a 2.2 kV, 50-Hz supply, determine
  - the secondary voltage on no-load,
  - the primary current when the secondary current is 200 A at 0.8 p.f. lagging, if the no-load current is 5 A at 0.2 p.f. lagging,
  - the power factor of the primary current. [239 V; 25-65 A; 0.715 lag]
- A 400/200-V, 1-phase transformer is supplying a load of 25 A at a p.f. of 0.866 lagging. On no-load the current and power factor are 2 A and 0.208 respectively. Calculate the current taken from the supply. [13.9 A lagging V1 by 36.1°]
- A transformer takes 10 A on no-load at a power factor of 0.1. The turn ratio is 4 : 1 (step down). If

a load is supplied by the secondary at 200 A and p.f. of 0.8, find the primary current and power factor (internal voltage drops in transformer are to be ignored). **[57.2 A; 0.717 lagging]**

5. A 1-phase transformer is supplied at 1,600 V on the h.v. side and has a turn ratio of 8 : 1. The transformer supplies a load of 20 kW at a power factor of 0.8 lag and takes a magnetising current of 2.0 A at a power factor of 0.2. Calculate the magnitude and phase of the current taken from the h.v. supply. **[17.15 A ; 0.753 lag] (Elect. Engg. Calcutta Univ. 1980)**

6. A 2,200/200-V, transformer takes 1 A at the H.T. side on no-load at a p.f. of 0.385 lagging. Calculate the iron losses.

If a load of 50 A at a power of 0.8 lagging is taken from the secondary of the transformer, calculate the actual primary current and its power factor. **[847 W; 5.44 A; 0.74 lag]**

7. A 400/200-V, I-phase transformer is supplying a load of 50 A at a power factor of 0.866 lagging. The no-load current is 2 A at 0.208 p.f. lagging. Calculate the primary current and primary power factor. **[26.4 A; 0.838 lag] (Elect. Machines-I, Indore Univ. 1980)**

### 32.11. Transformer with Winding Resistance but No Magnetic Leakage

An ideal transformer was supposed to possess no resistance, but in an actual transformer, there is always present some resistance of the primary and secondary windings. Due to this resistance, there is some voltage drop in the two windings. The result is that :

(i) The secondary terminal voltage  $V_2$  is vectorially less than the secondary induced e.m.f.  $E_2$  by an amount  $I_2 R_2$  where  $R_2$  is the resistance of the secondary winding. Hence,  $V_2$  is equal to the vector difference of  $E_2$  and resistive voltage drop  $I_2 R_2$ .

∴  $V_2 = E_2 - I_2 R_2$  ...vector difference

(ii) Similarly, primary induced e.m.f.  $E_1$  is equal to the vector difference of  $V_1$  and  $I_1 R_1$  where  $R_1$  is the resistance of the primary winding.

$E_1 = V_1 - I_1 R_1$  ...vector difference

Fig. 32.22

The vector diagrams for non-inductive, inductive and capacitive loads are shown in Fig. 32.22 (a), (b) and (c) respectively.

### 32.12. Equivalent Resistance

In Fig. 32.23 a transformer is shown whose primary and secondary windings have resistances of  $R_1$  and  $R_2$  respectively. The resistances have been shown external to the windings.

It would now be shown that the resistances of the two windings can be transferred to any one of the two windings. The advantage of concentrating both the resistances in one winding is that it makes calculations very simple and easy because one has then to work in one winding only. It will be proved that a resistance of  $R_2$  in secondary is equivalent to  $R_2/K^2$  in primary. The value  $R_2/K^2$  will be denoted by  $R_2'$ —the *equivalent secondary resistance as referred to primary*.

Fig. 32.23

The copper loss in secondary is  $I_2^2 R_2$ . This loss is supplied by primary which takes a current of  $I_1$ . Hence if  $R_2'$  is the *equivalent resistance in primary which would have caused the same loss* as  $R_2$  in secondary, then

$$I_1^2 R_2' = I_2^2 R_2 \text{ or } R_2' = (I_2/I_1)^2 R_2$$

Now, if *we neglect no-load current*  $I_0$ , then  $I_2/I_1 = 1/K$ \*. Hence,  $R_2' = R_2/K^2$

Similarly, equivalent primary resistance as referred to secondary is  $R_1' = K^2 R_1$

In Fig. 32.24, secondary resistance has been transferred to primary side leaving secondary circuit resistanceless. The resistance  $R_1 + R_2' = R_1 + R_2/K^2$  is known as the *equivalent or effective resistance of the transformer as referred to primary* and may be designated as  $R_{01}$ .

∴  $R_{01} = R_1 + R_2' = R_1 + R_2/K^2$

Similarly, the *equivalent resistance of the transformer as referred to secondary* is

$$R_{02} = R_2 + R_1' = R_2 + K^2 R_1$$

This fact is shown in Fig. 32.25 where all the resistances of the transformer has been concentrated in the secondary winding.

Fig. 32.24

Fig. 32.25

It is to be noted that

1. a resistance of  $R_1$  in primary is equivalent to  $K^2 R_1$  in secondary. Hence, it is called *equivalent resistance as referred to secondary* i.e.  $R_1'$ .
2. a resistance of  $R_2$  in secondary is equivalent to  $R_2/K^2$  in primary. Hence, it is called the *equivalent secondary resistance as referred to primary* i.e.  $R_2'$ .

3. Total or effective resistance of the transformer as referred to primary is

$$R_{01} = \text{primary resistance} + \text{equivalent secondary resistance as referred to primary} \\ = R_1 + R_2' = R_1 + R_2/K^2$$

4. Similarly, total transformer resistance as referred to secondary is,

$$R_{02} = \text{secondary resistance} + \text{equivalent primary resistance as referred to secondary} \\ = R_2 + R_1' = R_2 + K^2 R_1$$

\* Actually  $I_2 \neq 2/I_2' = 1/K$  and not  $I_2 \neq 2/I_1$ . However, if  $I_0$  is neglected, then  $I_2' = I_1$ .

**Note :** It is important to remember that

- (a) when shifting any primary resistance to the secondary, **multiply** it by  $K^2$  i.e. (transformation ratio)<sup>2</sup>.
- (b) when shifting secondary resistance to the primary, **divide** it by  $K^2$ .
- (c) however, when shifting any voltage from one winding to another only  $K$  is used.

### 32.13. Magnetic Leakage

In the preceding discussion, it has been assumed that all the flux linked with primary winding also links the secondary winding. But, in practice, it is impossible to realize this condition. It is found, however, that all the flux linked with primary does not link the secondary but part of it i.e.  $\Phi_{L1}$  completes its magnetic circuit by passing through air rather than around the core, as shown in Fig. 32.26. This leakage flux is produced when the m.m.f. due to primary ampere-turns existing between points  $a$  and  $b$ , acts along the leakage paths. Hence, this flux is known as **primary leakage flux** and is proportional to the primary ampere-turns alone because the secondary turns do not link the magnetic circuit of  $\Phi_{L1}$ . The flux  $\Phi_{L1}$  is in time phase with  $I_1$ . It induces an e.m.f.  $e_{L1}$  in primary but not in secondary.

Similarly, secondary ampere-turns (or m.m.f.) acting across points  $c$  and  $d$  set up leakage flux  $\Phi_{L2}$  which is linked with secondary winding alone (and not with primary turns). This flux  $\Phi_{L2}$  is in time phase with  $I_2$  and produces a self-induced e.m.f.  $e_{L2}$  in secondary (but not in primary).

At no load and light loads, the primary and secondary ampere-turns are small, hence leakage fluxes are negligible. But when load is increased, both primary and secondary windings carry huge currents. Hence, large m.m.f.s are set up which, while acting on leakage paths, increase the leakage flux.

As said earlier, the leakage flux linking with each winding, produces a self-induced e.m.f. in that winding. Hence, in effect, it is equivalent to a small choker or inductive coil in series with each winding such that voltage drop in each series coil is equal to that produced by leakage flux. In other words, **a transformer with magnetic leakage is equivalent to an ideal transformer with inductive coils connected in both primary and secondary circuits** as shown in Fig. 32.27 such that the internal e.m.f. in each inductive coil is equal to that due to the corresponding leakage flux in the actual transformer.

$$X_1 = e_{L1}/I_1 \text{ and } X_2 = e_{L2}/I_2$$

The terms  $X_1$  and  $X_2$  are known as primary and secondary **leakage reactances** respectively.

Following few points should be kept in mind :

1. The leakage flux links one or the other winding but **not both**, hence it in no way contributes to the transfer of energy from the primary to the secondary winding.
2. The primary voltage  $V_1$  will have to supply reactive drop  $I_1 X_1$  in addition to  $I_1 R_1$ . Similarly  $E_2$  will have to supply  $I_2 R_2$  and  $I_2 X_2$ .
3. In an actual transformer, the primary and secondary windings are not placed on separate legs or limbs as shown in Fig. 32.27 because due to their being widely separated, large primary and secondary leakage fluxes would result. These leakage fluxes are minimised by sectionalizing and interleaving the primary and secondary windings as in Fig. 32.6 or Fig. 32.8.

Fig. 32.26

Fig. 32.27

### 32.14. Transformer with Resistance and Leakage Reactance

In Fig. 32.28 the primary and secondary windings of a transformer with reactances taken out of the windings are shown. The primary impedance is given by

$$Z_1 = \sqrt{R_1^2 + X_1^2}$$

Similarly, secondary impedance is given by

$$Z_2 = \sqrt{R_2^2 + X_2^2}$$

The resistance and leakage reactance of each winding is responsible for some voltage drop in each winding. In primary, the leakage reactance drop is  $I_1 X_1$  (usually 1 or 2% of  $V_1$ ). Hence

$$V_1 = E_1 + I_1(R_1 + jX_1) = E_1 + I_1 Z_1$$

Similarly, there are  $I_2 R_2$  and  $I_2 X_2$  drops in secondary which combine with  $V_2$  to give  $E_2$ .

$$E_2 = V_2 + I_2(R_2 + jX_2) = V_2 + I_2 Z_2$$

The vector diagram for such a transformer for different kinds of loads is shown in Fig. 32.29. In these diagrams, vectors for resistive drops are drawn parallel to current vectors whereas reactive drops are perpendicular to the current vectors. The angle  $\phi_1$  between  $V_1$  and  $I_1$  gives the power factor angle of the transformer.

It may be noted that leakage reactances can also be transferred from one winding to the other in the same way as resistance.

$$\begin{aligned} \therefore X_2' &= X_2/K^2 \quad \text{and} \quad X_1' = K^2 X_2 \\ \text{and} \quad X_{01} &= X_1 + X_2' = X_1 + X_2/K^2 \quad \text{and} \quad X_{02} = X_2 + X_1' = X_2 + K^2 X_1 \end{aligned}$$

Fig. 32.28

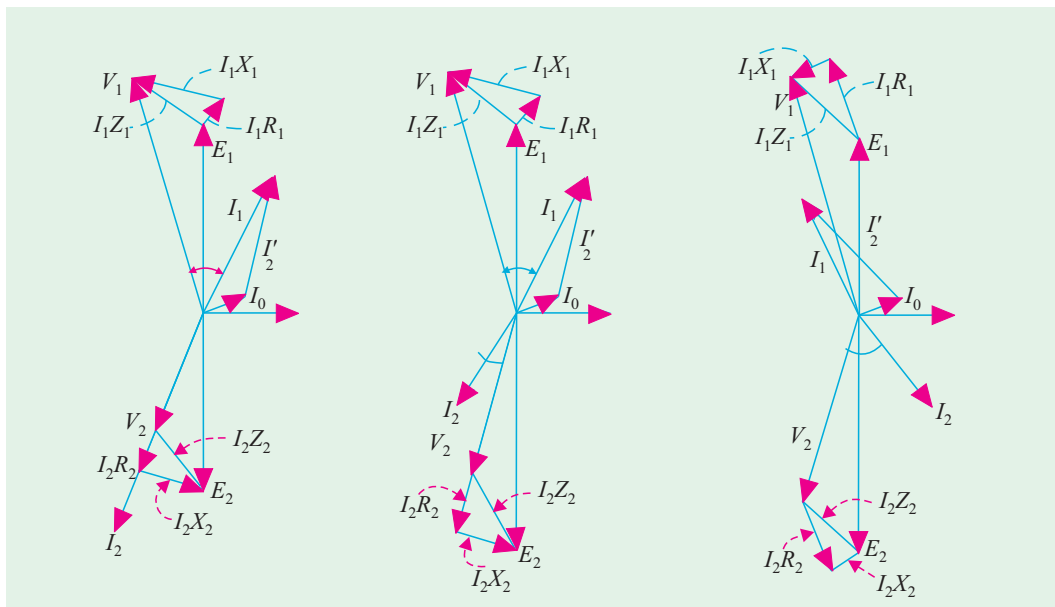

Fig. 32.29

Fig. 32.30 (a)

Fig. 32.30 (b)

It is obvious that total impedance of the transformer as referred to primary is given by

$$Z_{01} = \sqrt{(R_{01}^2 + X_{01}^2)} \quad \dots \text{Fig. 32.30 (a)}$$

and

$$Z_{02} = \sqrt{(R_{02}^2 + X_{02}^2)} \quad \dots \text{Fig. 32.30 (b)}$$

**Example 32.15.** A 30 kVA, 2400/120-V, 50-Hz transformer has a high voltage winding resistance of 0.1 Ω and a leakage reactance of 0.22 Ω. The low voltage winding resistance is 0.035 Ω and the leakage reactance is 0.012 Ω. Find the equivalent winding resistance, reactance and impedance referred to the (i) high voltage side and (ii) the low-voltage side.

(Electrical Machines-I, Bangalore Univ. 1987)

**Solution.**

$$K = 120/2400 = 1/20; R_1 = 0.1 \Omega, X_1 = 0.22 \Omega$$

$$R_2 = 0.035 \Omega \quad \text{and} \quad X_2 = 0.012 \Omega$$

(i) Here, high-voltage side is, obviously, the primary side. Hence, values as referred to primary side are

$$R_{01} = R_1 + R_2' = R_1 + R_2/K^2 = 0.1 + 0.035/(1/20)^2 = \mathbf{14.1 \Omega}$$

$$X_{01} = X_1 + X_2' = X_1 + X_2/K^2 = 0.22 + 0.012/(1/20)^2 = \mathbf{5.02 \Omega}$$

$$Z_{01} = \sqrt{R_{01}^2 + X_{01}^2} = \sqrt{14.1^2 + 5.02^2} = \mathbf{15 \Omega}$$

(ii)

$$R_{02} = R_2 + R_1' = R_2 + K^2 R_1 = 0.035 + (1/20)^2 \times 0.1 = \mathbf{0.03525 \Omega}$$

$$X_{02} = X_2 + X_1' = X_2 + K^2 X_1 = 0.012 + (1/20)^2 \times 0.22 = \mathbf{0.01255 \Omega}$$

$$Z_{02} = \sqrt{R_{02}^2 + X_{02}^2} = \sqrt{0.03525^2 + 0.01255^2} = \mathbf{0.0374 \Omega}$$

$$\text{(or } Z_{02} = K^2 Z_{01} = (1/20)^2 \times 15 = 0.0375 \Omega \text{)}$$

**Example 32.16.** A 50-kVA, 4,400/220-V transformer has  $R_1 = 3.45 \Omega$ ,  $R_2 = 0.009 \Omega$ . The values of reactances are  $X_1 = 5.2 \Omega$  and  $X_2 = 0.015 \Omega$ . Calculate for the transformer (i) equivalent resistance as referred to primary (ii) equivalent resistance as referred to secondary (iii) equivalent reactance as referred to both primary and secondary (iv) equivalent impedance as referred to both primary and secondary (v) total Cu loss, first using individual resistances of the two windings and secondly, using equivalent resistances as referred to each side.

(Elect. Engg.-I, Nagpur Univ. 1993)

**Solution.** Full-load

$$I_1 = 50,000/4,400 = 11.36 \text{ A (assuming 100\% efficiency)}$$

Full-load

$$I_2 = 50,000/220 = 227 \text{ A; } K = 220/4,400 = 1/20$$

(i)

$$R_{01} = R_1 + \frac{R_2}{K^2} = 3.45 + \frac{0.009}{(1/20)^2} = 3.45 + 3.6 = \mathbf{7.05 \Omega}$$

(ii)

$$R_{02} = R_2 + K^2 R_1 = 0.009 + (1/20)^2 \times 3.45 = 0.009 + 0.0086 = \mathbf{0.0176 \Omega}$$

Also,

$$R_{02} = K^2 R_{01} = (1/20)^2 \times 7.05 = 0.0176 \Omega \text{ (check)}$$

$$\begin{aligned}
 \text{(iii)} \quad X_{01} &= X_1 + X_2' = X_1 + X_2/K^2 = 5.2 + 0.015/(1/20)^2 = \mathbf{11.2 \Omega} \\
 X_{02} &= X_2 + X_1' = X_2 + K^2 X_1 = 0.015 + 5.2/20^2 = \mathbf{0.028 \Omega} \\
 \text{Also } X_{02} &= K^2 X_{01} = 11.2/400 = 0.028 \Omega \text{ (check)} \\
 \text{(iv)} \quad Z_{01} &= \sqrt{(R_{01}^2 + X_{01}^2)} = \sqrt{(7.05^2 + 11.2)^2} = \mathbf{13.23 \Omega} \\
 Z_{02} &= \sqrt{(R_{02}^2 + X_{02}^2)} = \sqrt{(0.0176^2 + 0.028)^2} = \mathbf{0.03311 \Omega} \\
 \text{Also } Z_{02} &= K^2 Z_{01} = 13.23/400 = 0.0331 \Omega \text{ (check)} \\
 \text{(v)} \quad \text{Cu loss} &= I_1^2 R_2 + I_2^2 R_2 = 11.36^2 \times 3.45 + 227^2 \times 0.009 = \mathbf{910 W} \\
 \text{Also Cu loss} &= I_1^2 R_{01} = 11.36^2 \times 7.05 = \mathbf{910 W} \\
 &= I_2^2 R_{02} = 227^2 \times 0.0176 = \mathbf{910 W}
 \end{aligned}$$

**Example 32.17.** A transformer with a 10 : 1 ratio and rated at 50-kVA, 2400/240-V, 50-Hz is used to step down the voltage of a distribution system. The low tension voltage is to be kept constant at 240 V.

(a) What load impedance connected to low-tension side will be loading the transformer fully at 0.8 power factor (lag) ?

(b) What is the value of this impedance referred to high tension side ?

(c) What is the value of the current referred to the high tension side ?

(Elect. Engineering-I, Bombay Univ. 1987)

**Solution. (a)** F. L.  $I_2 = 50,000/240 = 625/3$  A;  $Z_2 = \frac{240}{(625/3)} = \mathbf{1.142 \Omega}$

(b)  $K = 240/2400 = 1/10$

The secondary impedance referred to primary side is

$$Z_2' = Z_2/K^2 = 1.142/(1/10)^2 = \mathbf{114.2 \Omega}$$

(c) Secondary current referred to primary side is  $I_2' = KI_2 = (1/10) \times 625/3 = \mathbf{20.83 A}$

**Example 32.18.** The full-load copper loss on the h.v. side of a 100-kVA, 11000/317-V, 1-phase transformer is 0.62 kW and on the L.V. side is 0.48 kW.

(i) Calculate  $R_1$ ,  $R_2$  and  $R_3$  in ohms (ii) the total reactance is 4 per cent, find  $X_1$ ,  $X_2$  and  $X_3$  in ohms if the reactance is divided in the same proportion as resistance.

(Elect. Machines A.M.I.E., Sec. B, 1991)

**Solution. (i)** F.L.  $I_1 = 100 \times 10^3/11000 = 9.1$  A. F.L.  $I_2 = 100 \times 10^3/317 = 315.5$  A

Now,  $I_1^2 R_1 = 0.62$  kW or  $R_1 = 620/9.1^2 = 7.5 \Omega$

$$I_2^2 R_2 = 0.48 \text{ kW}, R_2 = 480/315.5^2 = 0.00482 \Omega$$

$$R_2' = R_2/K^2 = 0.00482 \times (11,000/317)^2 = 5.8 \Omega$$

$$\% \text{ reactance} = \frac{I_1 \times X_{01}}{V_1} \times 100 \text{ or } 4 = \frac{9.1 \times X_{01}}{11000} \times 100, X_{01} = 48.4 \Omega$$

$$X_1 + X_2' = 48.4 \Omega. \text{ Given } R_1/R_2' = X_1/X_2'$$

$$\text{or } (R_1 + R_2')/R_2' = (X_1 + X_2')/X_2' \quad (7.5 + 5.8)/5.8 = 48.4/X_2' \quad \therefore X_2' = 21.1 \Omega$$

$$\therefore X_1 = 48.4 - 21.1 = 27.3 \Omega, X_2 = 21.1 \times (317/11000)^2 = \mathbf{0.175 \Omega}$$

**Example 32.19.** The following data refer to a 1-phase transformer :

Turn ratio 19.5 : 1 ;  $R_1 = 25 \Omega$  ;  $X_1 = 100 \Omega$  ;  $R_2 = 0.06 \Omega$  ;  $X_2 = 0.25 \Omega$ . No-load current = 1.25 A leading the flux by  $30^\circ$ .

The secondary delivers 200 A at a terminal voltage of 500 V and p.f. of 0.8 lagging. Determine

by the aid of a vector diagram, the primary applied voltage, the primary p.f. and the efficiency.

(Elect. Machinery-I, Madras Univ. 1989)

**Solution.** The vector diagram is similar to Fig. 30.28 which has been redrawn as Fig. 32.31. Let us take  $V_2$  as the reference vector.

$$\begin{aligned} \therefore \quad V_2 &= 500 \angle 0^\circ = 500 + j0 \\ I_2 &= 200(0.8 - j0.6) = 160 - j120 \\ Z_2 &= (0.06 + j0.25) \\ E_2 &= V_2 + I_2 Z_2 \\ &= (500 + j0) + (160 - j120)(0.06 + j0.25) \\ &= 500 + (39.6 + j32.8) = 539.6 + j32.8 = 541 \angle 3.5^\circ \end{aligned}$$

Obviously,  $\beta = 3.5^\circ$

$$\begin{aligned} E_1 &= E_2/K = 19.5 E_2 = 19.5(539.6 + j32.8) \\ &= 10,520 + j640 \end{aligned}$$

$$\therefore -E_1 = -10,520 - j640 = 10,540 \angle 183.5^\circ$$

$$\begin{aligned} I_2' &= -I_2 K = (-160 + j120)/19.5 \\ &= -8.21 + j6.16 \end{aligned}$$

As seen from Fig. 32.31,  $I_0$  leads  $V_2$  by an angle  $= 3.5^\circ + 90^\circ + 30^\circ = 123.5^\circ$

$$\begin{aligned} \therefore I_0 &= 1.25 \angle 123.5^\circ \\ &= 1.25(\cos 123.5^\circ + j \sin 123.5^\circ) \\ &= 1.25(-\cos 56.5^\circ + j \sin 56.5^\circ) \\ &= -0.69 + j1.04 \end{aligned}$$

$$\begin{aligned} I_1 &= I_2' + I_0 = (-8.21 + j6.16) + (-0.69 + j1.04) \\ &= -8.9 + j7.2 = 11.45 \angle 141^\circ \end{aligned}$$

$$\begin{aligned} V_2 &= -E_1 + I_1 Z_1 \\ &= -10,520 - j640 + (-8.9 + j7.5)(25 + j100) \\ &= -10,520 - j640 - 942 - j710 \\ &= -11,462 - j1350 \\ &= 11,540 \angle 186.7^\circ \end{aligned}$$

Phase angle between  $V_1$  and  $I_1$  is  $= 186.7^\circ - 141^\circ = 45.7^\circ$

$$\therefore \text{primary p.f.} = \cos 45.7^\circ = \mathbf{0.698 \text{ (lag)}}$$

$$\begin{aligned} \text{No-load primary input power} &= V_1 I_0 \sin \phi_0 \\ &= 11,540 \times 1.25 \times \cos 60^\circ = 7,210 \text{ W} \end{aligned}$$

$$R_{02} = R_2 + K^2 R_1 = 0.06 + 25/19.5^2 = 0.1257 \Omega$$

$$\text{Total Cu loss as referred to secondary} = I_2^2 R_{02} = 200^2 \times 0.1257 = 5,030 \text{ W}$$

$$\text{Output} = V_2 I_2 \cos \phi_2 = 500 \times 200 \times 0.8 = 80,000 \text{ W}$$

$$\text{Total losses} = 5030 + 7210 = 12,240 \text{ W}$$

$$\text{Input} = 80,000 + 12,240 = 92,240 \text{ W}$$

$$\eta = 80,000/92,240 = 0.8674 \text{ or } \mathbf{86.74\%}$$

Fig. 32.31

**Example 32.20.** A 100 kVA, 1100/220 V, 50 Hz, single-phase transformer has a leakage impedance of  $(0.1 + j0.4)$  ohm for the H.V. winding and  $(0.006 + j0.015)$  ohm for the L.V. winding. Find the equivalent winding resistance, reactance and impedance referred to the H.V. and L.V. sides.

(Bharathiar Univ. Nov. 1997)

**Solution.** Turns ratio =  $(N_1/N_2) = (V_1/V_2) = 1100/220 = 5$

(i) Referred to H.V. side :

Resistance =  $r_1 + r_2 = 0.1 + (25 \times 0.006) = 0.25$  ohm  
 Reactance =  $x_1 + x_2' = 0.4 + (25 \times 0.015) = 0.775$  ohm  
 Impedance =  $(0.25^2 + 0.775^2)^{0.5} = 0.8143$  ohm

(ii) Referred to L.V. side :

Resistance =  $0.25/25 = 0.01$   
 (or resistance =  $0.006 + (0.1/25) = 0.01$  ohm)  
 Reactance =  $0.775/25 = 0.031$  ohm  
 Impedance =  $0.8143/25 = 0.0326$  ohm

### 32.15. Simplified Diagram

The vector diagram of Fig. 32.29 may be considerably simplified if the no-load current  $I_0$  is neglected. Since  $I_0$  is 1 to 3 per cent of full-load primary current  $I_1$ , it may be neglected without serious error. Fig. 32.32 shows the diagram of Fig. 32.29 with  $I_0$  omitted altogether.

In Fig. 32.32,  $V_2, V_1, \phi_2$  are known, hence  $E_2$  can be found by adding vectorially  $I_2 R_2$  and  $I_2 X_2$  to  $V_2$ . Similarly,  $V_1$  is given by the vector addition of  $I_1 R_1$  and  $I_1 X_1$  to  $E_1$ . All the voltages on the primary side can be transferred to the secondary side as shown in figure, where the upper part of the diagram has been rotated through  $180^\circ$ . However, it should be noted that each voltage or voltage drop should be multiplied by transformation ratio  $K$ .

The lower side of the diagram has been shown separately in Fig. 32.34 laid horizontally where vector for  $V_2$  has been taken along X-axis.

Fig. 32.32

It is a simple matter to find transformer regulation as shown in Fig. 32.34 or Fig. 32.35.

It may be noted that  $V_2 = KV_1 - I_2(R_{02} + jX_{02}) = KV_1 - I_2Z_{02}$ .

Fig. 32.33

Fig. 32.34

\* Also,  $V_1 = (V_2 + I_2 Z_{02}) \#3/K$

**32.16. Total Approximate Voltage Drop in a Transformer**

When the transformer is on *no-load*, then  $V_1$  is approximately equal to  $E_1$ . Hence  $E_2 = KE_1 = KV_1$ . Also,  $E_2 = {}_0V_2$  where  ${}_0V_2$  is secondary terminal voltage on *no-load*, hence no-load secondary terminal voltage is  $KV_1$ . The secondary voltage on load is  $V_2$ . The difference between the two is  $I_2 Z_{02}$  as shown in Fig. 32.35. The approximate voltage drop of the transformer *as referred to secondary* is found thus :

Fig. 32.35

With  $O$  as the centre and radius  $OC$  draw an arc cutting  $OA$  produced at  $M$ . The total voltage drop  $I_2 Z_{02} = AC = AM$  which is approximately equal to  $AN$ . From  $B$  draw  $BD$  perpendicular on  $OA$  produced. Draw  $CN$  perpendicular to  $OM$  and draw  $BL$  parallel to  $OM$ .

Approximate voltage drop  
 $= AN = AD + DN$   
 $= I_2 R_{02} \cos \phi + I_2 X_{02} \sin \phi$

where  $\phi_1 = \phi_2 = \phi$  (approx).

This is the value of approximate voltage drop for a *lagging* power factor.

The different figures for unity and leading power factors are shown in Fig. 32.36 (a) and (b) respectively.

Fig. 32.36

The approximate voltage drop for *leading* power factor becomes

$$(I_2 R_{02} \cos \phi \pm I_2 X_{02} \sin \phi)$$

In general, approximate voltage drop is  $(I_2 R_{02} \cos \phi \pm I_2 X_{02} \sin \phi)$

It may be noted that approximate voltage drop as referred to primary is

$$(I_1 R_{01} \cos \phi \pm I_1 X_{01} \sin \phi)$$

$$\% \text{ voltage drop in secondary is} = \frac{I_2 R_{02} \cos \phi \pm I_2 X_{02} \sin \phi}{{}_0V_2} \times 100$$

$$= \frac{100 \times I_2 R_{02}}{{}_0V_2} \cos \phi \pm \frac{100 I_2 X_{02}}{{}_0V_2} \sin \phi$$

$$= v_r \cos \phi \pm v_x \sin \phi$$

where  $v_r = \frac{100 I_2 R_{02}}{{}_0V_2} = \text{percentage resistive drop} = \frac{100 I_1 R_{01}}{V_1}$

$$v_x = \frac{100 I_2 X_{02}}{{}_0V_2} = \text{percentage reactive drop} = \frac{100 I_1 X_{01}}{V_1}$$

### 32.17. Exact Voltage Drop

With reference to Fig. 32.35, it is to be noted that exact voltage drop is  $AM$  and not  $AN$ . If we add the quantity  $NM$  to  $AN$ , we will get the exact value of the voltage drop.

Considering the right-angled triangle  $OCN$ , we get

$$NC^2 = OC^2 - ON^2 = (OC + ON)(OC - ON) = (OC + ON)(OM - ON) = 2 OC \times NM$$

$$\therefore NM = NC^2 / 2 \cdot OC \quad \text{Now, } NC = LC - LN = LC - BD$$

$$\therefore NC = I_2 X_{02} \cos \phi - I_2 R_{02} \sin \phi \quad \therefore NM = \frac{(I_2 X_{02} \cos \phi - I_2 R_{02} \sin \phi)^2}{2_0 V_2}$$

$\therefore$  For a **lagging** power factor, exact voltage drop is

$$= AN + NM = (I_2 R_{02} \cos \phi + I_2 X_{02} \sin \phi) + \frac{(I_2 X_{02} \cos \phi - I_2 R_{02} \sin \phi)^2}{2_0 V_2}$$

For a **leading** power factor, the expression becomes

$$= (I_2 R_{02} \cos \phi - I_2 X_{02} \sin \phi) + \frac{(I_2 X_{02} \cos \phi + I_2 R_{02} \sin \phi)^2}{2_0 V_2}$$

In general, the voltage drop is

$$= (I_2 R_{02} \cos \phi \pm I_2 X_{02} \sin \phi) + \frac{(I_2 X_{02} \cos \phi \pm I_2 R_{02} \sin \phi)^2}{2_0 V_2}$$

Percentage drop is

$$= \frac{(I_2 R_{02} \cos \phi \pm I_2 X_{02} \sin \phi) \times 100}{_0 V_2} + \frac{(I_2 X_{02} \cos \phi \mp I_2 R_{02} \sin \phi)^2 \times 100}{2_0 V_2^2}$$

$$= (v_r \cos \phi \pm v_x \sin \phi) + (1/200) (v_x \cos \phi \mp v_r \sin \phi)^2$$

The upper signs are to be used for a **lagging** power factor and the lower ones for a **leading** power factor.

**Example 32.21.** A 230/460-V transformer has a primary resistance of  $0.2 \Omega$  and reactance of  $0.5 \Omega$  and the corresponding values for the secondary are  $0.75 \Omega$  and  $1.8 \Omega$  respectively. Find the secondary terminal voltage when supplying 10 A at 0.8 p.f. lagging.

(Electric Machines-II, Bangalore Univ. 1991)

**Solution.**

$$K = 460/230 = 2; R_{02} = R_2 + K^2 R_1 = 0.75 + 2^2 \times 0.2 = 1.55 \Omega$$

$$X_{02} = X_2 + K^2 X_1 = 1.8 + 2^2 \times 0.5 = 3.8 \Omega$$

$$\text{Voltage drop} = I_2 (R_{02} \cos \phi + X_{02} \sin \phi) = 10 (1.55 \times 0.8 + 3.8 \times 0.6) = 35.2 \text{V}$$

$$\therefore \text{Secondary terminal voltage} = 460 - 35.2 = \mathbf{424.8 \text{ V}}$$

**Example 32.22.** Calculate the regulation of a transformer in which the percentage resistance drops is 1.0% and percentage reactance drop is 5.0% when the power factor is (a) 0.8 lagging (b) unity and (c) 0.8 leading.

(Electrical Engineering, Banaras Hindu Univ. 1988)

**Solution.** We will use the approximate expression of Art 30.16.

$$(a) \text{ p.f.} = \cos \phi = 0.8 \text{ lag} \quad \mu = v_r \cos \phi + v_x \sin \phi = 1 \times 0.8 + 5 \times 0.6 = \mathbf{3.8\%}$$

$$(b) \text{ p.f.} = \cos \phi = 1 \quad \mu = 1 \times 1 + 5 \times 0 = \mathbf{1\%}$$

$$(c) \text{ p.f.} = \cos \phi = 0.8 \text{ lead} \quad \mu = 1 \times 0.8 - 5 \times 0.6 = \mathbf{-2.2\%}$$

**Example 32.23.** A transformer has a reactance drop of 5% and a resistance drop of 2.5%. Find the lagging power factor at which the voltage regulation is maximum and the value of this regulation.

(Elect. Engg. Punjab Univ. 1991)

**Solution.** The percentage voltage regulation ( $\mu$ ) is given by

$$\mu = v_r \cos \phi + v_x \sin \phi$$

where  $v_r$  is the percentage resistive drop and  $v_x$  is the percentage reactive drop.

Differentiating the above equation, we get  $\frac{d\mu}{d\phi} = -v_r \sin \phi + v_x \cos \phi$

For regulation to be maximum,  $d\mu/d\phi = 0 \therefore -v_r \sin \phi + v_x \cos \phi = 0$

or  $\tan \phi = v_x/v_r = 5/2.5 = 2 \therefore \phi = \tan^{-1}(2) = 63.5^\circ$  Now,  $\cos \phi = 0.45$  and  $\sin \phi = 0.892$

Maximum percentage regulation =  $(2.5 \times 0.45) + (5 \times 0.892) = 5.585$

Maximum percentage regulation is **5.585** and occurs at a power factor of **0.45** (lag).

**Example 32.24.** Calculate the percentage voltage drop for a transformer with a percentage resistance of 2.5% and a percentage reactance of 5% of rating 500 kVA when it is delivering 400 kVA at 0.8 p.f. lagging. **(Elect. Machinery-I, Indore Univ. 1987)**

**Solution.** 
$$\% \text{ drop} = \frac{(\%R) I \cos \phi}{I_f} + \frac{(\%X) I \sin \phi}{I_f}$$

where  $I_f$  is the full-load current and  $I$  the actual current.

$$\therefore \% \text{ drop} = \frac{(\%R)kW}{kVA \text{ rating}} + \frac{(\%X) kVAR}{kVA \text{ rating}}$$

In the present case,  $kW = 400 \times 0.8 = 320$  and  $kVAR = 400 \times 0.6 = 240$

$$\therefore \% \text{ drop} = \frac{2.5 \times 320}{500} + \frac{5 \times 240}{500} = 4\%$$

### 32.18. Equivalent Circuit

The transformer shown diagrammatically in Fig. 32.37 (a) can be resolved into an equivalent circuit in which the resistance and leakage reactance of the transformer are imagined to be external to the winding whose only function then is to transform the voltage (Fig. 32.37 (b)). The no-load

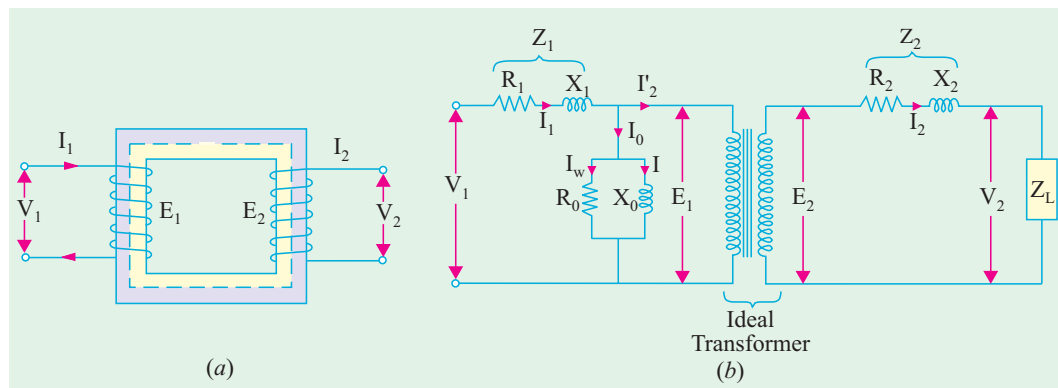

Fig. 32.37

current  $I_0$  is simulated by pure inductance  $X_0$  taking the magnetising component  $I_\mu$  and a non-inductive resistance  $R_0$  taking the working component  $I_w$  connected in parallel across the primary circuit. The value of  $E_1$  is obtained by subtracting vectorially  $I_1 Z_1$  from  $V_1$ . The value of  $X_0 = E_1/I_0$  and of  $R_0 = E_1/I_w$ . It is clear that  $E_1$  and  $E_2$  are related to each other by expression

$$E_2/E_1 = N_2/N_1 = K.$$

To make transformer calculations simpler, it is preferable to transfer voltage, current and impedance

either to the primary or to the secondary. In that case, we would have to work in one winding only which is more convenient.

The primary equivalent of the secondary induced voltage is  $E_2' = E_2/K = E_1$ .

Similarly, primary equivalent of secondary terminal or output voltage is  $V_2' = V_2/K$ .

Primary equivalent of the secondary current is  $I_2' = KI_2$ .

For transferring secondary impedance to primary  $K^2$  is used.

$$R_2' = R_2/K^2, X_2' = X_2/K^2, Z_2' = Z_2/K^2$$

The same relationship is used for shifting an external load impedance to the primary.

The secondary circuit is shown in Fig. 32.38 (a) and its equivalent primary values are shown in Fig. 32.38 (b).

Fig. 32.38

The total equivalent circuit of the transformer is obtained by adding in the primary impedance as shown in Fig. 32.39. This is known as the exact equivalent circuit but it presents a somewhat harder circuit problem to solve. A simplification can be made by transferring the exciting circuit across the terminals as in Fig. 32.40 or in Fig. 32.41 (a). It should be noted that in this case  $X_0 = V_1/I_\mu$ .

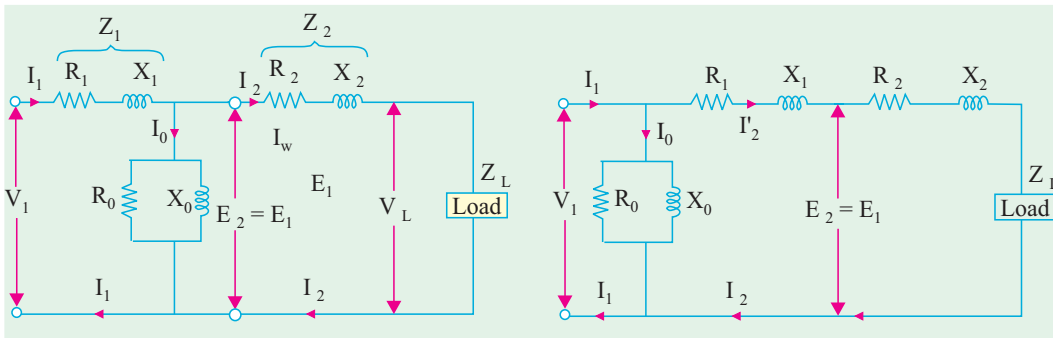

Fig. 32.39

Fig. 32.40

Further simplification may be achieved by omitting  $I_0$  altogether as shown in Fig. 32.41 (b).

From Fig. 32.39 it is found that total impedance between the input terminal is

$$Z = Z_1 + Z_m || (Z_2' + Z_L') = \left( Z_1 + \frac{Z_m (Z_2' + Z_L')}{Z_m + (Z_2' + Z_L')} \right)$$

where  $Z_2' = R_2' + jX_2'$  and  $Z_m$  = impedance of the exciting circuit.

This is so because there are two parallel circuits, one having an impedance of  $Z_m$  and the other having  $Z_2'$  and  $Z_L'$  in series with each other.

$$\therefore V_1 = I_1 \left[ Z_1 + \frac{Z_m (Z_2' + Z_L')}{Z_m + (Z_2' + Z_L')} \right]$$

Fig. 32.41 (a)

Fig. 32.41 (b)

**Example 32.25.** The parameters of a 2300/230 V, 50-Hz transformer are given below :

$$R_1 = 0.286 \Omega \quad R_2' = 0.319 \Omega \quad R_0 = 250 \Omega$$

$$X_1 = 0.73 \Omega \quad X_2' = 0.73 \Omega \quad X_0 = 1250 \Omega$$

The secondary load impedance  $Z_L = 0.387 + j 0.29$ . Solve the exact equivalent circuit with normal voltage across the primary.

**Solution.**

$$K = 230/2300 = 1/10; \quad Z_L = 0.387 + j0.29$$

$$Z_L' = Z_L/K^2 = 100(0.387 + j0.29) = 38.7 + j29 = 48.4 \angle 36.8^\circ$$

$$\therefore Z_2' + Z_L' = (38.7 + 0.319) + j(29 + 0.73) = 39.02 + j29.73 = 49.0 \angle 37.3^\circ$$

$$Y_m = (0.004 - j0.0008); \quad Z_m = 1/Y_m = 240 + j48 = 245 \angle 11.3^\circ$$

$$Z_m + (Z_2' + Z_L') = (240 + j48) + (39 + j29.7) = 279 \angle 15.6^\circ$$

$$\therefore I_1 = \frac{V_1}{Z_1 + \frac{Z_m(Z_2' + Z_L')}{Z_m + (Z_2' + Z_L')}} = \left[ \frac{2300 \angle 0^\circ}{0.286 + j0.73 + 41.4 \angle 33^\circ} \right]$$

$$= \frac{2300 \angle 0^\circ}{42 \angle 33.7^\circ} = 54.8 \angle -33.7^\circ$$

Now 
$$I_2' = I_1 \times \frac{Z_m}{(Z_2' + Z_L') + Z_m} = 54.8 \angle -33.7^\circ \times \frac{245 \angle 11.3^\circ}{290 \angle 15.6^\circ}$$

$$= 54.8 \angle -33.7^\circ \times 0.845 \angle -4.3^\circ = 46.2 \angle -38^\circ$$

$$I_0 = I_1 \times \frac{(Z_2' + Z_L')}{Z_m + (Z_2' + Z_L')} = 54.8 \angle -33.7^\circ \times \frac{49 \angle 37.3^\circ}{290 \angle 15.6^\circ}$$

$$= 54.8 \angle -33.7^\circ \times 0.169 \angle 21.7^\circ = 9.26 \angle -12^\circ$$

Input power factor

$$= \cos 33.7^\circ = 0.832 \text{ lagging}$$

Power input

$$= V_1 I_1 \cos \phi_1 = 2300 \times 54.8 \times 0.832 = 105 \text{ kW}$$

Power output

$$= 46.2^2 \times 38.7 = 82.7 \text{ kW}$$

Primary Cu loss

$$= 54.8^2 \times 0.286 = 860 \text{ W}$$

Secondary Cu loss

$$= 46.2^2 \times 0.319 = 680 \text{ W}; \quad \text{Core loss} = 9.26^2 \times 240 = 20.6 \text{ kW}$$

$$\eta = (82.7/105) \times 100 = 78.8\%; \quad V_2' = I_2' Z_L' = 46.2 \times 48.4 = 2,240 \text{ V}$$

$$\therefore \text{Regulation} = \frac{2300 - 2240}{2240} \times 100 = 2.7\%$$

**Example 32.26.** A transformer has a primary winding with a voltage-rating of 600 V. Its secondary-voltage rating is 1080 V with an additional tap at 720 V. An 8 kW resistive load is connected across 1080-V output terminals. A purely inductive load of 10kVA is connected across the tapping point and common secondary terminal so as to get 720 V. Calculate the primary current and its power-factor. Correlate it with the existing secondary loads. Neglect losses and magnetizing current. (Nagpur University, Winter 1999)

**Solution.** Loads are connected as shown in Fig. 32.42.

$$I_{r_2} = \frac{8000}{1080} = 7.41 \text{ at unity p.f.}$$

$$I_{L_2} = 10000/720 = 13.89 \text{ at zero lagging p.f.}$$

These are reflected on to the primary sides with appropriate ratios of turns, with corresponding power-factors. If the corresponding transformed currents are represented by the above symbols modified by dashed superscripts,

$$I'_{r_2} = 7.41 \times 1080/600 = 13.34 \text{ A at unity p.f.}$$

$$I'_{L_2} = 13.89 \times 720/600 = 16.67 \text{ A at zero lag. p.f.}$$

Hence,

$$I_{r_2} = [I'^2_{r_2} + I'^2_{L_2}]^{0.5} = 21.35 \text{ A, at } 0.625 \text{ lag p.f.}$$

Fig. 32.42

**Correlation :** Since losses and magnetizing current are ignored, the calculations for primary current and its power-factor can also be made with data pertaining to the two Loads (in kW/kVAR), as supplied by the 600 V source.

$S$  = Load to be supplied : 8 kW at unity p.f. and 10 kVAR lagging

Thus,

$$S = P + jQ = 8 - j 10 \text{ kVA}$$

$$S = (8^2 + 10^2)^{0.5} = 12.8 \text{ kVA}$$

$$\text{Power - factor} = \cos \phi = 8/12.8 = 0.625 \text{ lag}$$

$$\text{Primary current} = 12.8 \times 1000/600 = 21.33 \text{ A}$$

### 32.19. Transformer Tests

As shown in Ex 32.25, the performance of a transformer can be calculated on the basis of its equivalent circuit which contains (Fig. 32.41) four main parameters, the equivalent resistance  $R_{01}$  as referred to primary (or secondary  $R_{02}$ ), the equivalent leakage reactance  $X_{01}$  as referred to primary (or secondary  $X_{02}$ ), the core-loss conductance  $G_0$  (or resistance  $R_0$ ) and the magnetising susceptance  $B_0$  (or reactance  $X_0$ ). These constants or parameters can be easily determined by two tests (i) **open-circuit test** and (ii) **short-circuit test**. These tests are very economical and convenient, because they furnish the required information without actually loading the transformer. In fact, the testing of very large a.c. machinery consists of running two tests similar to the open and short-circuit tests of a transformer.

Small transformer

32.20. Open-circuit or No-load Test

The purpose of this test is to determine no-load loss or core loss and no-load  $I_0$  which is helpful in finding  $X_0$  and  $R_0$ .

One winding of the transformer – whichever is convenient but usually high voltage winding – is left open and the other is connected to its supply of normal voltage and frequency. A wattmeter  $W$ , voltmeter  $V$  and an ammeter  $A$  are connected in the low-voltage winding *i.e.* primary winding in the present case.

Fig. 32.43

With normal voltage applied to the primary, normal flux will be set up in the core, hence normal iron losses will occur which are recorded by the wattmeter. As the primary no-load current  $I_0$  (as measured by ammeter) is small (usually 2 to 10% of rated load current), Cu loss is negligibly small in primary and nil in secondary (it being open). Hence, the wattmeter reading represents practically the core loss under no-load condition (and which is the same for all loads as pointed out in Art. 32.9).

It should be noted that since  $I_0$  is itself very small, the pressure coils of the wattmeter and the voltmeter are connected such that the current in them does not pass through the current coil of the wattmeter.

Sometimes, a high-resistance voltmeter is connected across the secondary. The reading of the voltmeter gives the induced e.m.f. in the secondary winding. This helps to find transformation ratio  $K$ .

The no-load vector diagram is shown in Fig. 32.16. If  $W$  is the wattmeter reading (in Fig. 32.43), then

$$W = V_1 I_0 \cos \phi_0 \quad \therefore \quad \cos \phi_0 = W / V_1 I_0$$

$$\therefore \quad I_\mu = I_0 \sin \phi_0, \quad I_w = I_0 \cos \phi_0 \quad \therefore \quad X_0 = V_1 / I_\mu \quad \text{and} \quad R_0 = V_1 / I_w$$

Or since the current is practically all-exciting current when a transformer is on no-load (*i.e.*  $I_0 \cong I_\mu$ ) and as the voltage drop in primary leakage impedance is small\*, hence the exciting admittance  $Y_0$  of the transformer is given by  $I_0 = V_1 Y_0$  or  $Y_0 = I_0 / V_1$ .

$$\text{The exciting conductance } G_0 \text{ is given by } W = V_1^2 G_0 \text{ or } G_0 = W / V_1^2.$$

$$\text{The exciting susceptance } B_0 = \sqrt{(Y_0^2 - G_0^2)}$$

**Example. 32.27.** In no-load test of single-phase transformer, the following test data were obtained :

Primary voltage : 220 V ; Secondary voltage : 110 V ;

Primary current : 0.5 A ; Power input : 30 W.

Find the following :

(i) The turns ratio (ii) the magnetising component of no-load current (iii) its working (or loss) component (iv) the iron loss.

Resistance of the primary winding = 0.6 ohm.

Draw the no-load phasor diagram to scale.

(Elect. Machine A.M.I.E. 1990)

**Solution.** (i) Turn ratio,  $N_1 / N_2 = 220 / 110 = 2$

(ii)  $W = V_1 I_0 \cos \phi_0$ ;  $\cos \phi_0 = 30 / 220 \times 0.5 = 0.273$ ;  $\sin \phi_0 = 0.962$

$$I_\mu = I_0 \sin \phi_0 = 0.5 \times 0.962 = 0.48 \text{ A}$$

\* If it is not negligibly small, then  $I_0 = E_1 Y_0$  *i.e.* instead of  $V_1$  we will have to use  $E_1$ .

$$\begin{aligned} \text{(iii)} \quad I_w &= I_0 \cos \phi_0 = 0.5 \times 0.273 = 0.1365 \text{ A} \\ \text{(iv)} \quad \text{Primary Cu loss} &= I_0^2 R_1 = 0.5^2 \times 0.6 = 0.15 \text{ W} \\ \therefore \quad \text{Iron loss} &= 30 - 0.15 = 29.85 \text{ W} \end{aligned}$$

**Example 32.28.** A 5 kVA 200/1000 V, 50 Hz, single-phase transformer gave the following test results :

O.C. Test (L.V. Side) : 2000 V, 1.2 A, 90 W

S.C. Test (H.V. Side) : 50 V, 5A, 110 W

- (i) Calculate the parameters of the equivalent circuit referred to the L.V. side.  
(ii) Calculate the output secondary voltage when delivering 3 kW at 0.8 p.f. lagging, the input primary voltage being 200 V. Find the percentage regulation also.

(Nagpur University, November 1998)

**Solution.** (i) Shunt branch parameters from O.C. test (L.V. side) :

$$\begin{aligned} R_0 &= V^2/P_i = 200^2/90 = 444 \text{ ohms}, \quad I_{\omega} = 200/444 = 0.45 \text{ amp} \\ I_{\mu} &= (1.2^2 - 0.45^2)^{0.5} = 1.11 \text{ amp}, \quad X_m = 200/1.11 = 180.2 \text{ ohms} \end{aligned}$$

All these are referred to L.V. side.

(ii) Series-branch Parameters from S.C test (H.V side) :

Since the S.C. test has been conducted from H.V. side, the parameters will refer to H.V. side.

They should be converted to the parameters referred to L.V. side by transforming them suitably.

From S.C. Test readings,  $Z = 50/5 = 10 \text{ ohms}$

$$R = 110/25 = 4.40 \text{ ohms}, \quad X = (10^2 - 4.4^2)^{0.5} = 8.9 \text{ ohms}$$

These are referred to H.V. side.

For referring these to L.V. side, transform these using the ratio of turns, as follows :

$$\begin{aligned} r_1 &= 4.40 \times (200/1000)^2 = 0.176 \text{ ohm} \\ x_1 &= 8.98 \times (200/1000)^2 = 0.36 \text{ ohm} \end{aligned}$$

Equivalent circuit can be drawn with  $R_0$  and  $X_m$  calculated above and  $r_1$  and  $x_1$  as above.

L.V. Current at rated load =  $5000/200 = 25 \text{ A}$

L.V. Current at 3 kW at 0.8 lagging p.f. =  $(3000/0.8)/200 = 18.75 \text{ A}$

$$\begin{aligned} \text{Regulation at this load} &= 18.75 (r_1 \cos \phi + x_1 \sin \phi) \\ &= 18.75 (0.176 \times 0.80 + 0.36 \times 0.6) \\ &= +6.69 \text{ Volts} = + (6.69/200) \times 100\% = +3.345\% \end{aligned}$$

This is referred to L.V. side, and positive sign means voltage drop.

Regulation in volts ref. to H.V. side =  $6.69 \times 1000/200 = 33.45 \text{ V}$

With 200 V across primary (i.e. L.V. side), the secondary (i.e. H.V. side)

$$\text{terminal voltage} = 1000 - 33.45 = 966.55 \text{ V}$$

**Note:** Since approximate formula for voltage regulation has been used, the procedure is simpler, and faster.

### 32.21. Separation of Core Losses

The core loss of a transformer depends upon the frequency and the maximum flux density when the volume and the thickness of the core laminations are given. The core loss is made up of two parts (i) hysteresis loss  $W_h = PB_{\max}^{1.6} f$  as given by Steinmetz's empirical relation and (ii) eddy current loss  $W_e = QB_{\max}^2 f^2$  where  $Q$  is a constant. The total core-loss is given by

$$W_i = W_h + W_e = PB_{\max}^{1.6} f^2 + QB_{\max}^2 f^2$$

If we carry out two experiments using two different frequencies but the same maximum flux density, we should be able to find the constants  $P$  and  $Q$  and hence calculate hysteresis and eddy current losses separately.

**Example 32.29.** In a transformer, the core loss is found to be 52 W at 40 Hz and 90 W at 60 Hz measured at same peak flux density. Compute the hysteresis and eddy current losses at 50 Hz.

(Elect. Machines, Nagpur Univ. 1993)

**Solution.** Since the flux density is the same in both cases, we can use the relation

$$\text{Total core loss } W_i = Af + Bf^2 \quad \text{or} \quad W_i/f = A + Bf$$

$$\therefore 52/40 = A + 40B \quad \text{and} \quad 90/60 = A + 60B; \quad \therefore A = 0.9 \quad \text{and} \quad B = 0.01$$

At 50 Hz, the two losses are

$$W_h = Af = 0.9 \times 50 = 45 \text{ W}; \quad W_e = Bf^2 = 0.01 \times 50^2 = 25 \text{ W}$$

**Example 32.30.** In a power loss test on a 10 kg specimen of sheet steel laminations, the maximum flux density and waveform factor are maintained constant and the following results were obtained:

Frequency (Hz)	25	40	50	60	80
Total loss (watt)	18.5	36	50	66	104

Calculate the eddy current loss per kg at a frequency of 50 Hz.

(Elect. Measur. A.M.I.E. Sec B, 1991)

**Solution.** When flux density and wave form factor remain constant, the expression for iron loss can be written as

$$W_i = Af + Bf^2 \quad \text{or} \quad W_i/f = A + Bf$$

The values of  $W_i/f$  for different frequencies are as under :

$f$	25	40	50	60	80
$W_i/f$	0.74	0.9	1.0	1.1	1.3

The graph between  $f$  and  $W_i/f$  has been plotted in Fig. 32.44. As seen from it,  $A = 0.5$  and  $B = 0.01$

$$\therefore \text{Eddy current loss at 50 Hz} = Bf^2 = 0.01 \times 50^2 = 25 \text{ W}$$

$$\therefore \text{Eddy current loss/kg} = 25/10 = 2.5 \text{ W}$$

**Example 32.31.** In a test for the determination of the losses of a 440-V, 50-Hz transformer, the total iron losses were found to be 2500 W at normal voltage and frequency. When the applied voltage and frequency were 220 V and 25 Hz, the iron losses were found to be 850 W. Calculate the eddy-current loss at normal voltage and frequency.

(Elect. Inst. and Meas. Punjab Univ. 1991)

**Solution.** The flux density in both cases is the same because in second case voltage as well as frequency are halved. Flux density remaining the same, the eddy current loss is proportional to  $f^2$  and hysteresis loss  $\propto f$ .

$$\text{Hysteresis loss } \propto f = Af \quad \text{and} \quad \text{eddy current loss } \propto f^2 = Bf^2$$

where  $A$  and  $B$  are constants.

$$\text{Total iron loss} \quad W_i = Af + Bf^2 \quad \therefore \quad \frac{W_i}{f} = A + Bf \quad \dots(i)$$

Now, when  $f = 50 \text{ Hz} : W_i = 2500 \text{ W}$

and when  $f = 25 \text{ Hz} ; W_i = 850 \text{ W}$

Using these values in (i) above, we get, from Fig. 32.44

$$2,500/50 = A + 50B \quad \text{and} \quad 850/25 = A + 25B \quad \therefore \quad B = 16/25 = 0.64$$

Hence, at normal p.d. and frequency

$$\text{eddy current loss} = Bf^2 = 0.64 \times 50^2 = \mathbf{1600 \text{ W}}$$

$$\text{Hysteresis loss} = 2500 - 1600 = 900 \text{ W}$$

Fig. 32.44

**Example 32.32.** When a transformer is connected to a 1000-V, 50-Hz supply the core loss is 1000 W, of which 650 is hysteresis and 350 is eddy current loss. If the applied voltage is raised to 2,000 V and the frequency to 100 Hz, find the new core losses.

**Solution.** Hysteresis loss  $W_h \propto B_{\max}^{1.6} f = PB_{\max}^{1.6} f$

Eddy current loss  $W_e \propto B_{\max}^2 f^2 = QB_{\max}^2 f^2$

From the relation  $E = 4.44 fNB_{\max}$  A volt, we get  $B_{\max} \propto E/f$

Putting this value of  $B_{\max}$  in the above equations, we have

$$W_h = P \left( \frac{E}{f} \right)^{1.6} f = PE^{1.6} f^{-0.6} \quad \text{and} \quad W_e = Q \left( \frac{E}{f} \right)^2 f^2 = QE^2$$

In the first case,

$$E = 1000 \text{ V}, f = 50 \text{ Hz}, W_h = 650 \text{ W}, W_e = 350 \text{ W}$$

$$\therefore 650 = P \times 1000^{1.6} \times 50^{-0.6} \quad \therefore P = 650 \times 1000^{-1.6} \times 50^{0.6}$$

Similarly,

$$350 = Q \times 1000^2 \quad \therefore Q = 350 \times 1000^{-2}$$

Hence, constants  $P$  and  $Q$  are known.

Using them in the second case, we get

$$W_h = (650 \times 1000^{-1.6} \times 50^{0.6}) \times 2000^{1.6} \times 100^{-0.6} = 650 \times 2 = 1,300 \text{ W}$$

$$W_e = (350 \times 1000^{-2}) \times 2,000^2 = 350 \times 4 = 1,400 \text{ W}$$

$$\therefore \text{Core loss under new condition is} = 1,300 + 1,400 = \mathbf{2700 \text{ W}}$$

#### Alternative Solution

Here, both voltage and frequency are doubled, leaving the flux density unchanged.

#### With 1000 V at 50 Hz

$$W_h = Af \text{ or } 650 = 50A; A = 13$$

$$W_e = Bf^2 \text{ or } 350 = B \times 50^2; B = 7/50$$

#### With 2000 V at 100 Hz

$$W_h = Af = 13 \times 100 = 1300 \text{ W and}$$

$$W_e = Bf^2 = (7/50) \times 100^2 = 1400 \text{ W}$$

$$\therefore \text{New core loss} = 1300 + 1400 = \mathbf{2700 \text{ W}}$$

**Example 32.33.** A transformer with normal voltage impressed has a flux density of 1.4 Wb/m<sup>2</sup> and a core loss comprising of 1000 W eddy current loss and 3000 W hysteresis loss. What do these losses become under the following conditions ?

- increasing the applied voltage by 10% at rated frequency.
- reducing the frequency by 10% with normal voltage impressed.
- increasing both impressed voltage and frequency by 10 per cent.

(Electrical Machinery-I, Madras Univ. 1985)

**Solution.** As seen from Ex. 32.32

$$W_h = PE^{1.6} f^{-0.6} \quad \text{and} \quad W_e = QE^2$$

$$\text{From the given data, we have } 3000 = PE^{1.6} f^{-0.6} \quad \dots(i)$$

$$\text{and } 1000 = QE^2 \quad \dots(ii)$$

where  $E$  and  $f$  are the normal values of primary voltage and frequency.

$$(a) \text{ Here voltage becomes } = E + 10\% E = 1.1 E$$

$$\text{The new hysteresis loss is } W_h = P(1.1 E)^{1.6} f^{-0.6} \quad \dots(iii)$$

$$\text{Dividing Eq. (iii) by (i), we get } \frac{W_h}{3000} = 1.1^{1.6}; W_h = 3000 \times 1.165 = \mathbf{3495 \text{ W}}$$

The new eddy-current loss is

$$W_e = Q (1.1 \cdot E)^2 \quad \therefore \quad \frac{W_e}{1000} = 1.1^2$$

$$\therefore \quad W_e = 1000 \times 1.21 = \mathbf{1210 \text{ W}}$$

(b) As seen from Eq. (i) above eddy-current loss would not be effected. The new hysteresis loss is

$$W_h = PE^{1.6} (0.9 f)^{-0.6} \dots (iv)$$

From (i) and (iv), we get  $\frac{W_h}{3000} = 0.9^{-0.6}$ ,  $W_h = 3000 \times 1.065 = \mathbf{3,196 \text{ W}}$

(c) In this case, both  $E$  and  $f$  are increased by 10%. The new losses are as under :

$$W_h = P (1.1 E)^{1.6} (1.1 f)^{-0.6}$$

$$\therefore \quad \frac{W_h}{3000} = 1.1^{1.6} \times 1.1^{-0.6} = 1.165 \times 0.944$$

$$\therefore \quad W_h = 3000 \times 1.165 \times 0.944 = \mathbf{3,299 \text{ W}}$$

As  $W_e$  is unaffected by changes in  $f$ , its value is the same as found in (a) above i.e. **1210 W**

**Example 32.34.** A transformer is connected to 2200 V, 40 Hz supply. The core-loss is 800 watts out of which 600 watts are due to hysteresis and the remaining, eddy current losses. Determine the core-loss if the supply voltage and frequency are 3300 V and 60 Hz respectively.

(Bharathiar Univ. Nov. 1997)

**Solution.** For constant flux density (i.e. constant  $V/f$  ratio), which is fulfilled by 2200/40 or 3300/60 figures in two cases,

$$\text{Core-loss} = Af + Bf^2$$

First term on the right-hand side represents hysteresis-loss and the second term represents the eddy-current loss.

At 40 Hz,  $800 = 600 + \text{eddy current loss}$ .

Thus,  $Af = 600$ , or  $A = 15$

$$Bf^2 = 200, \text{ or } B = 200/1600 = 0.125$$

At 60 Hz,  $\text{core-loss} = 15 \times 60 + 0.125 \times 60^2$

$$= 900 + 450$$

$$= 1350 \text{ watts}$$

### 32.22 Short-Circuit or Impedance Test

This is an economical method for determining the following :

(i) Equivalent impedance ( $Z_{01}$  or  $Z_{02}$ ), leakage reactance ( $X_{01}$  or  $X_{02}$ ) and total resistance ( $R_{01}$  or  $R_{02}$ ) of the transformer as referred to the winding in which the measuring instruments are placed.

(ii) Cu loss at full load (and at any desired load). This loss is used in calculating the efficiency of the transformer.

(iii) Knowing  $Z_{01}$  or  $Z_{02}$ , the total voltage drop in the transformer as referred to primary or secondary can be calculated and hence regulation of the transformer determined.

In this test, one winding, usually the low-voltage winding, is solidly short-circuited by a thick conductor (or through an ammeter which may serve the additional purpose of indicating rated load current) as shown in Fig. 32.45.

Fig. 32.45

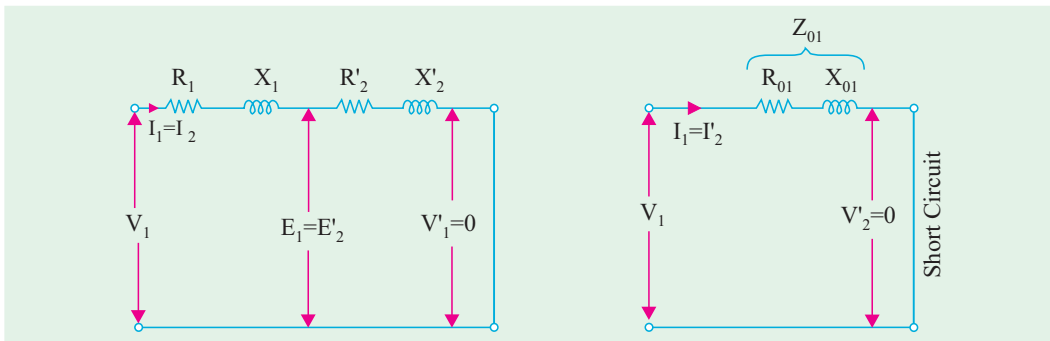

Fig. 32.46

A low voltage (usually 5 to 10% of normal primary voltage) at correct frequency (though for Cu losses it is not essential) is applied to the primary and is cautiously increased till full-load currents are flowing both in primary and secondary (as indicated by the respective ammeters).

Since, in this test, the applied voltage is a small percentage of the normal voltage, the mutual flux  $\Phi$  produced is also a small percentage of its normal value (Art. 32.6). Hence, core losses are very small with the result that the wattmeter reading represent the full-load Cu loss or  $I^2R$  loss for the whole transformer *i.e.* both primary Cu loss and secondary Cu loss. The equivalent circuit of the transformer under short-circuit condition is shown in Fig. 32.46. If  $V_{sc}$  is the voltage required to circulate rated load currents, then  $Z_{01} = V_{sc}/I_1$

Also  $W = I_1^2 R_{01}$

$\therefore R_{01} = W/I_1$

$\therefore X_{01} = \sqrt{(Z_{01}^2 - R_{01}^2)}$

In Fig. 32.47 (a) the equivalent circuit vector diagram for the short-circuit test is shown. This diagram is the same as shown in Fig. 32.34 except that all the quantities are referred to the primary side. It is obvious that the entire voltage  $V_{sc}$  is consumed in the impedance drop of the two windings.

Fig. 32.47

If  $R_1$  can be measured, then knowing

$R_{01}$ , we can find  $R_2' = R_{01} - R_1$ . The impedance triangle can then be divided into the appropriate equivalent triangles for primary and secondary as shown in Fig. 32.47 (b).

### 32.23. Why Transformer Rating in kVA ?

As seen, Cu loss of a transformer depends on current and iron loss on voltage. Hence, total transformer loss depends on volt-ampere (VA) and not on phase angle between voltage and current *i.e.* it is independent of load power factor. That is why rating of transformers is in kVA and not in kW.

**Example 32.35.** The primary and secondary windings of a 30 kVA 76000/230, V, 1-phase transformer have resistance of 10 ohm and 0.016 ohm respectively. The reactance of the transformer referred to the primary is 34 ohm. Calculate the primary voltage required to circulate full-load current when the secondary is short-circuited. What is the power factor on short circuit ?

(Elect. Machines AMIE Sec. B 1991)

**Solution.**

$$K = 230/6000 = 23/600, X_{01} = 34 \Omega,$$

$$R_{01} = R_1 + R_2/K^2 = 10 + 0.016 (600/23)^2 = 20.9 \Omega$$

$$Z_{01} = \sqrt{R_{01}^2 + X_{01}^2} = \sqrt{20.9^2 + 34^2} = 40 \Omega$$

$$\text{F.L., } I_1 = 30,000/6000 = 5 \text{ A ; } V_{SC} = I_1 Z_{01} = 5 \times 40 = 200 \text{ V}$$

$$\text{Short circuit p.f.} = R_{01}/Z_{01} = 20.9/40 = 0.52$$

**Example 32.36.** Obtain the equivalent circuit of a 200/400-V, 50-Hz, 1-phase transformer from the following test data :

O.C test : 200 V, 0.7 A, 70 W – on L.V. side

S.C. test : 15 V, 10 A, 85 W – on H.V. side

Calculate the secondary voltage when delivering 5 kW at 0.8 p.f. lagging, the primary voltage being 200V. (Electrical Machinery-I, Madras Univ. 1987)

**Solution. From O.C. Test**

$$V_1 I_0 \cos \phi_0 = W_0$$

$$\therefore 200 \times 0.7 \times \cos \phi_0 = 70$$

$$\cos \phi_0 = 0.5 \text{ and } \sin \phi_0 = 0.866$$

$$I_w = I_0 \cos \phi_0 = 0.7 \times 0.5 = 0.35 \text{ A}$$

$$I_\mu = I_0 \sin \phi_0 = 0.7 \times 0.866 = 0.606 \text{ A}$$

$$R_0 = V_1/I_w = 200/0.35 = 571.4 \Omega$$

$$X_0 = V_1/I_\mu = 200/0.606 = 330 \Omega$$

As shown in Fig. 32.48, these values refer to primary i.e. low-voltage side.

Fig. 32.48

**From S.C. Test**

It may be noted that in this test, instruments have been placed in the secondary i.e. high-voltage winding whereas the low-voltage winding i.e. primary has been short-circuited.

Now, as shown in Art. 32.32

$$Z_{02} = V_{sc}/I_2 = 15/10 = 1.5 \Omega ; K = 400/200 = 2$$

$$Z_{01} = Z_{02}/K^2 = 1.5/4 = 0.375 \Omega$$

Also  $I_2^2 R_{02} = W ; R_{02} = 85/100 = 0.85 \Omega$

$$R_{01} = R_{02}/K^2 = 0.85/4 = 0.21 \Omega$$

$$X_{01} = \sqrt{Z_{01}^2 - R_{01}^2} = \sqrt{0.375^2 - 0.21^2} = 0.31 \Omega$$

$$\text{Output kVA} = 5/0.8 ; \text{ Output current } I_2 = 5000/0.8 \times 400 = 15.6 \text{ A}$$

This value of  $I_2$  is approximate because  $V_2$  (which is to be calculated as yet) has been taken equal to 400 V (which, in fact, is equal to  $E_2$  or  $V_2$ ).

Now,  $Z_{02} = 1.5 \Omega, R_{02} = 0.85 \Omega \therefore X_{02} = \sqrt{1.5^2 - 0.85^2} = 1.24 \Omega$

Total transformer drop as referred to secondary

$$= I_2 (R_{02} \cos \phi_2 + X_{02} \sin \phi_2) = 15.6 (0.85 \times 0.8 + 1.24 \times 0.6) = 22.2 \text{ V}$$

$$\therefore V_2 = 400 - 22.2 = \mathbf{377.8 \text{ V}}$$

**Example 32.37.** Starting from the ideal transformer, obtain the approximate equivalent circuit of a commercial transformer in which all the constants are lumped and represented on one side.

A 1-phase transformer has a turn ratio of 6. The resistance and reactance of primary winding are 0.9  $\Omega$  and 5  $\Omega$  respectively and those of the secondary are 0.03  $\Omega$  and 0.13  $\Omega$  respectively. If 330 -V at 50-Hz be applied to the high voltage winding with the low-voltage winding short-circuited, find the current in the low-voltage winding and its power factor. Neglect magnetising current.

**Solution.**

$$\text{Here } K = 1/6; R_{01} = R_1 + R'_2 = 0.9 + (0.03 \times 36) = 1.98 \Omega$$

$$X_{01} = X_1 + X'_2 = 5 + (0.13 \times 36) = 9.68 \Omega$$

$$\therefore Z_{01} = \sqrt{(9.68^2 + 1.98^2)} = 9.9 \Omega; V_{SC} = 330 \text{ V}$$

$$\therefore \text{Full-load primary current } I_1 = V_{sc}/Z_{01} = 330/9.9 = 100/3 \text{ A}$$

$$\text{As } I_0 \text{ is negligible, hence } I_1 = I'_2 = 100/3 \text{ A. Now, } I'_2 = KI_2$$

$$\text{F.L. secondary current } I_2 = I'_2 K = (100/3) \times 6 = 200 \text{ A}$$

$$\text{Now, Power input on short-circuit} = V_{SC} I_1 \cos \phi_{SC} = \text{Cu loss} = I_1^2 R_{01}$$

$$\therefore (100/3)^2 \times 1.98 = 330 \times (100/3) \times \cos \phi_{SC}; \cos \phi_{SC} = \mathbf{0.2}$$

**Example 32.38.** A 1-phase, 10-kVA, 500/250-V, 50-Hz transformer has the following constants:

Reactance : primary 0.2  $\Omega$ ; secondary 0.5  $\Omega$

Resistance : primary 0.4  $\Omega$ ; secondary 0.1  $\Omega$

Resistance of equivalent exciting circuit referred to primary,  $R_0 = 1500 \Omega$

Reactance of equivalent exciting circuit referred to primary,  $X_0 = 750 \Omega$

What would be the reading of the instruments when the transformer is connected for the open-circuit and short-circuit tests ?

**Solution.** While solving this question, reference may please be made to Art. 30.20 and 30.22.

**O.C. Test**

$$I_\mu = V_1/X_0 = 500/750 = 2/3 \text{ A}; I_w = V_1/R_0 = 500/1500 = 1/3 \text{ A}$$

$$\therefore I_0 = \sqrt{[(1/3)^2 + (2/3)^2]} = 0.745 \text{ A}$$

$$\text{No-load primary input} = V_1 I_w = 500 \times 1/3 = 167 \text{ W}$$

Instruments used in primary circuit are : voltmeter, ammeter and wattmeter, their readings being 500 V, 0.745 A and 167 W respectively.

**S.C. Test**

Suppose S.C. test is performed by short-circuiting the l.v. winding i.e. the secondary so that all instruments are in primary.

$$R_{01} = R_1 + R'_2 = R_1 + R_2/K^2; \text{ Here } K = 1/2 \quad \therefore R_{01} = 0.2 + (4 \times 0.5) = 2.2 \Omega$$

$$\text{Similarly, } X_{01} = X_1 + X'_2 = 0.4 + (4 \times 0.1) = 0.8 \Omega$$

$$Z_{01} = \sqrt{(2.2^2 + 0.8^2)} = 2.341 \Omega$$

Full-load primary current

$$I_1 = 10,000/500 = 20 \text{ A} \quad \therefore V_{SC} = I_1 Z_{01} = 20 \times 2.341 = 46.8 \text{ V}$$

$$\text{Power absorbed} = I_1^2 R_{01} = 20^2 \times 2.2 = 880 \text{ W}$$

Primary instruments will read : **46.8 V, 20 A, 880 W.**

**Example 32.39.** The efficiency of a 1000-kVA, 110/220 V, 50-Hz, single-phase transformer, is 98.5 % at half full-load at 0.8 p.f. leading and 98.8 % at full-load unity p.f. Determine (i) iron loss (ii) full-load copper loss and (iii) maximum efficiency at unity p.f.

(Elect. Engg. AMIETE Sec. A Dec. 1991)

**Solution.** Output at F.L. unity p.f. = 1000  $\times$  1 = 1000 kW

$$\text{F.L. input} = 1000/0.988 = 1012.146 \text{ kW}$$

$$\text{F.L. losses} = 1012.146 - 1000 = 12.146 \text{ kW}$$

If F.L. Cu and iron losses are  $x$  and  $y$  respectively then

$$x + y = 12.146 \text{ kW} \quad \dots(i)$$

Input at half F.L. 0.8 p.f. =  $500 \times 0.8/0.985 = 406.091$  kW

Total losses at half F.L. =  $406.091 - 400 = 6.091$  kW

Cu loss at half-load =  $x (1/2)^2 = x/4$

$\therefore x/4 + y = 6.091$  ... (ii)

From Eqn. (i) and (ii), we get (i)  $x = 8.073$  kW and (ii)  $y = 4.073$  kW

(iii) kVA for  $\eta_{max} = 1000 \times \sqrt{4.073/8.073} = 710.3$  kVA

Output at u.p.f. =  $710.3 \times 1 = 710.3$  kW

Cu loss = iron loss =  $4.037$  kW ; Total loss =  $2 \times 4.037 = 8.074$  kW

$\therefore \eta_{max} = 710.3/(710.3 + 8.074) = 0.989$  or 98.9 %

**Example 32.40.** The equivalent circuit for a 200/400-V step-up transformer has the following parameters referred to the low-voltage side.

Equivalent resistance =  $0.15 \Omega$  ; Equivalent reactance =  $0.37 \Omega$

Core-loss component resistance =  $600 \Omega$  ; Magnetising reactance =  $300 \Omega$

When the transformer is supplying a load at 10 A at a power factor of 0.8 lag, calculate (i) the primary current (ii) secondary terminal voltage. (Electrical Machinery-I, Bangalore Univ. 1989)

**Solution.** We are given the following :

$R_{01} = 0.15 \Omega, X_{01} = 0.37 \Omega ; R_0 = 600 \Omega, X_0 = 300 \Omega$

Using the approximate equivalent circuit of Fig. 32.41, we have,

$I_\mu = V_1/X_0 = 200/300 = (2/3)$  A

$I_w = V_1/R_0 = 200/600 = (1/3)$  A

$I_0 = \sqrt{I_\mu^2 + I_w^2} = \sqrt{(2/3)^2 + (1/3)^2} = 0.745$  A

As seen from Fig. 32.49

$\tan \theta = \frac{I_w}{I_\mu} = \frac{1/3}{2/3} = \frac{1}{2} ; \theta = 26.6^\circ$

$\therefore \phi_0 = 90^\circ - 26.6^\circ = 63.4^\circ$  ; Angle between  $I_0$  and

$I'_2 = 63.4^\circ - 36.9^\circ = 26.5^\circ ; K = 400/200 = 2$

$I'_2 = KI_2 = 2 \times 10 = 20$  A

(i)  $I_1 = (0.745^2 + 20^2 + 2 \times 0.745 \times 20 \times \cos 26.5^\circ)^{1/2}$   
= **20.67 A**

(ii)  $R_{02} = K^2 R_{01} = 2^2 \times 0.15 = 0.6 \Omega$

$X_{02} = 2^2 \times 0.37 = 1.48 \Omega$

Approximate voltage drop

=  $I_2 (R_{02} \cos \phi + X_{02} \sin \phi)$

=  $10(0.6 \times 0.8 + 1.48 \times 0.6) = 13.7$  V

$\therefore$  Secondary terminal voltage =  $400 - 13.7$

= **386.3 V**

Fig. 32.49

**Example 32.41.** The low voltage winding of a 300-kVA, 11,000/2500-V, 50-Hz transformer has 190 turns and a resistance of 0.06. The high-voltage winding has 910 turns and a resistance of 1.6  $\Omega$ . When the l.v. winding is short-circuited, the full-load current is obtained with 550-V applied to the h.v. winding. Calculate (i) the equivalent resistance and leakage reactance as referred to h.v. side and (ii) the leakage reactance of each winding.

**Solution.** Assuming a full-load efficiency of 0.985, the full-load primary current is

$$= 300,000/0.985 \times 11,000 = 27.7\text{A}$$

$$\therefore Z_{01} = 550/27.7 = 19.8 \Omega ; R'_2 = R^2/K^2 = 0.06 (910/190)^2 = 1.38 \Omega$$

$$\therefore R_{01} = R_1 + R'_2 = 1.6 + 1.38 = 2.98 \Omega$$

$$X_{01} = \sqrt{(Z_{01}^2 - R_{01}^2)} = \sqrt{(19.8^2 - 2.98^2)} = 19.5 \Omega$$

Let us make another assumption that for each winding the ratio (reactance/resistance) is the same, then

$$X_1 = 19.5 \times 1.6/2.98 = 10.5 \Omega$$

$$X'_2 = 19.5 \times 1.38/2.98 = 9.0 \Omega ; X_2 = 9(190/910)^2 = 0.39 \Omega$$

(a)  $R_{01} = 2.98 \Omega ; X_{01} = 19.5 \Omega$  (b)  $X_1 = 10.5 \Omega ; X_2 = 0.39 \Omega$

**Example 32.42.** A 230/115 volts, single phase transformer is supplying a load of 5 Amps, at power factor 0.866 lagging. The no-load current is 0.2 Amps at power factor 0.208 lagging. Calculate the primary current and primary power factor.  
(Nagpur University Summer 2000)

**Solution.** L.V. current of 5 amp is referred to as a 2.5 amp current on the primary (= H.V.) side, at 0.866 lagging p.f. To this, the no load current should be added, as per the phasor diagram in Fig. 32.50. The phase angle of the load-current is 30° lagging. The no load current has a phase angle of 80° lagging. Resultant of these two currents has to be worked out. Along the reference, active components are added.

Fig. 32.50. Phasor diagram for Currents

$$\text{Active components of currents} = 2.5 \times 0.866 + 0.2 \times 0.208$$

$$= 2.165 + 0.0416$$

$$= 2.2066 \text{ amp}$$

Along the perpendicular direction, the reactive components get added up.

$$\text{Reactive component} = 2.5 \times 0.5 + 0.2 \times 0.9848$$

$$= 1.25 + 0.197 = 1.447 \text{ amp.}$$

$$I_1 = 2.2066 - j 1.447$$

$$\phi = \tan^{-1} \frac{1.447}{2.2066} = 33.25^\circ ; \text{ as shown}$$

### Tutorial Problems 32.3

- The S.C. test on a 1-phase transformer, with the primary winding short-circuited and 30 V applied to the secondary gave a wattmeter reading of 60 W and secondary current of 10 A. If the normal applied primary voltage is 200, the transformation ratio 1 :2 and the full-load secondary current 10 A, calculate the secondary terminal p.d. at full-load current for (a) unity power factor (b) power factor 0.8 lagging. If any approximations are made, they must be explained. [394 V, 377.6 V]
- A single-phase transformer has a turn ratio of 6, the resistances of the primary and secondary windings are 0.9 Ω and 0.025 Ω respectively and the leakage reactances of these windings are 5.4 Ω and 0.15 Ω respectively. Determine the voltage to be applied to the low-voltage winding to obtain a current of 100 A in the short-circuited high voltage winding. Ignore the magnetising current. [82 V]
- Draw the equivalent circuit for a 3000/400-V, I-phase transformer on which the following test results were obtained. Input to high voltage winding when 1.v. winding is open-circuited : 3000 V, 0.5 A, 500

W. Input to l.v. winding when h.v. winding is short-circuited : 11 V, 100 A, 500 W. Insert the appropriate values of resistance and reactance.

$$[R_0 = 18,000 \Omega, X_0 = 6,360 \Omega, R_{01} = 2.81 \Omega, X_{01} = 5.51 \Omega] \text{ (I.E.E. London)}$$

4. The iron loss in a transformer core at normal flux density was measured at frequencies of 30 and 50 Hz, the results being 30 W and 54 W respectively. Calculate (a) the hysteresis loss and (b) the eddy current loss at 50 Hz. [44 W, 10 W]
  5. An iron core was magnetised by passing an alternating current through a winding on it. The power required for a certain value of maximum flux density was measured at a number of different frequencies. Neglecting the effect of resistance of the winding, the power required per kg of iron was 0.8 W at 25 Hz and 2.04 W at 60 Hz. Estimate the power needed per kg when the iron is subject to the same maximum flux density but the frequency is 100 Hz. [3.63 W]
  6. The ratio of turns of a 1-phase transformer is 8, the resistances of the primary and secondary windings are  $0.85 \Omega$  and  $0.012 \Omega$  respectively and leakage reactances of these windings are  $4.8 \Omega$  and  $0.07 \Omega$  respectively. Determine the voltage to be applied to the primary to obtain a current of 150 A in the secondary circuit when the secondary terminals are short-circuited. Ignore the magnetising current. [176.4 W]
  7. A transformer has no-load losses of 55 W with a primary voltage of 250 V at 50 Hz and 41 W with a primary voltage of 200 V at 40 Hz. Compute the hysteresis and eddy current losses at a primary voltage of 300 volts at 60 Hz of the above transformer. Neglect small amount of copper loss at no-load. [43.5 W ; 27 W] (Elect. Machines AMIE Sec. B. (E-3) Summer 1992)
  8. A 20 kVA, 2500/250 V, 50 Hz, 1-phase transformer has the following test results :  
O.C. Test (l.v. side) : 250 V, 1.4 A, 105 W  
S.C. Test (h.v. side) : 104 V, 8 A, 320 W  
Compute the parameters of the approximate equivalent circuit referred to the low voltage side and draw the circuit. ( $R_0 = 592.5 \Omega$  ;  $X_0 = 187.2 \Omega$  ;  $R_{02} = 1.25 \Omega$  ;  $X_{12} = 3 \Omega$ )  
(Elect. Machines A.M.I.E. Sec. B Summer 1990)
  9. A 10-kVA, 2000/400-V, single-phase transformer has resistances and leakage reactances as follows :  
 $R_1 = 5.2 \Omega$ ,  $X_1 = 12.5 \Omega$ ,  $R_2 = 0.2 \Omega$ ,  $X_2 = 0.5 \Omega$   
Determine the value of secondary terminal voltage when the transformer is operating with rated primary voltage with the secondary current at its rated value with power factor 0.8 lag. The no-load current can be neglected. Draw the phasor diagram. [376.8 V] (Elect. Machines, A.M.I.E. Sec B, 1989)
  10. A 1000-V, 50-Hz supply to a transformer results in 650 W hysteresis loss and 400 W eddy current loss. If both the applied voltage and frequency are doubled, find the new core losses. [ $W_h = 1300 \text{ W}$  ;  $W_e = 1600 \text{ W}$ ] (Elect. Machine, A.M.I.E. Sec. B, 1993)
  11. A 50 kVA, 2200/110 V transformer when tested gave the following results :  
O.C. test (L.V. side) : 400 W, 10 A, 110 V.  
S.C. test (H.V. side) : 808 W, 20.5 A, 90 V.  
Compute all the parameters of the equivalent ckt. referred to the H.V. side and draw the resultant ckt. (Rajiv Gandhi Technical University, Bhopal 2000)
- [Shunt branch :  $R_0 = 12.1 \text{ k-ohms}$ ,  $X_m = 4.724 \text{ k-ohms}$  Series branch :  $r = 1.923 \text{ ohms}$ ,  $x = 4.39 \text{ ohms}$ ]

### 32.24. Regulation of a Transformer

1. When a transformer is loaded with a *constant primary voltage*, the secondary voltage decreases\* because of its internal resistance and leakage reactance.

Let  ${}_0V_2 =$  secondary terminal voltage at *no-load*.

---

\* Assuming lagging power factor. It will increase if power factor is leading.

=  $E_2 = EK_1 = K V_1$  because at no-load the impedance drop is negligible.

$V_2$  = secondary terminal voltage on full-load.

The change in secondary terminal voltage from no-load to full-load is  $= {}_0V_2 - V_2$ . This change divided by  ${}_0V_2$  is known as regulation 'down'. If this change is divided by  $V_2$ , i.e., full-load secondary terminal voltage, then it is called regulation 'up'.

$$\therefore \quad \% \text{ regn 'down'} = \frac{{}_0V_2 - V_2}{{}_0V_2} \times 100 \quad \text{and} \quad \% \text{ regn 'up'} = \frac{{}_0V_2 - V_2}{V_2} \times 100$$

In further treatment, unless stated otherwise, regulation is to be taken as regulation 'down'.

We have already seen in Art. 32.16 (Fig. 32.35) that the change in secondary terminal voltage from no-load to full-load, expressed as a percentage of no-load secondary voltage is,

$$= v_r \cos \phi \pm v_x \sin \phi \quad (\text{approximately})$$

Or more accurately

$$= (v_r \cos \phi \pm v_x \sin \phi) + \frac{1}{200} (v_x \cos \phi \mp v_r \sin \phi)^2$$

$$\therefore \quad \% \text{ regn} = v_r \cos \phi \pm v_x \sin \phi \quad \dots \text{approximately.}$$

The lesser this value, the better the transformer, because a good transformer should keep its secondary terminal voltage as constant as possible under all conditions of load.

(2) The regulation may also be explained in terms of primary values.

In Fig. 32.51 (a) the approximate equivalent circuit of a transformer is shown and in Fig. 32.51 (b), (c) and (d) the vector diagrams corresponding to different power factors are shown.

The secondary *no-load* terminal voltage as referred to primary is  $E'_2 = E_2/K = E_1 = V_1$  and if the secondary full-load voltage as referred to primary is  $V'_2 (= V_2/K)$  then

$$\% \text{ regn} = \frac{V_1 - V'_2}{V_1} \times 100$$

Fig. 32.51

From the vector diagram, it is clear that if angle between  $V_1$  and  $V'_2$  is neglected, then the value of numerical difference  $V_1 - V'_2$  is given by  $(I_1 R_{01} \cos \phi + I_1 X_{01} \sin \phi)$  for lagging p.f.

$$\therefore \quad \% \text{ regn} = \frac{I_1 R_{01} \cos \phi + I_1 X_{01} \sin \phi}{V_1} \times 100 = v_r \cos \phi + v_x \sin \phi$$

where  $\frac{I_1 R_{01} \times 100}{V_1} = v_r$  and  $\frac{I_1 X_{01} \times 100}{V_1} = v_x$  ...Art. 32.16

As before, if angle between  $V_1$  and  $V'_2$  is not negligible, then

$$\% \text{ regn} = (v_r \cos \phi \pm v_x \sin \phi) + \frac{1}{200} (v_x \cos \phi \mp v_r \sin \phi)^2$$

(3) In the above definitions of regulation, *primary voltage was supposed to be kept constant* and the changes in secondary terminal voltage were considered.

As the transformer is loaded, the secondary terminal voltage falls (for a lagging p.f.). Hence, to keep the output voltage constant, the primary voltage must be increased. The rise in primary voltage required to maintain rated output voltage from no-load to full-load at a given power factor expressed as percentage of rated primary voltage gives the regulation of the transformer.

Suppose primary voltage has to be raised from its rated value  $V_1$  to  $V_1'$ , then

$$\% \text{ regn.} = \frac{V_1' - V_1}{V_1} \times 100$$

**Example 32.43.** A-100 kVA transformer has 400 turns on the primary and 80 turns on the secondary. The primary and secondary resistances are 0.3  $\Omega$  and 0.01  $\Omega$  respectively and the corresponding leakage reactances are 1.1 and 0.035  $\Omega$  respectively. The supply voltage is 2200 V. Calculate (i) equivalent impedance referred to primary and (ii) the voltage regulation and the secondary terminal voltage for full load having a power factor of 0.8 leading.

(Elect. Machines, A.M.I.E. Sec. B, 1989)

**Solution.**  $K = 80/400 = 1/5$ ,  $R_1 = 0.3 \Omega$ ,  $R_{01} = R_1 + R_2/K^2 = 0.3 + 0.01/(1/5)^2 = 0.55 \Omega$

$$X_{01} = X_1 + X_2/K^2 = 1.1 + 0.035/(1/5)^2 = 1.975 \Omega$$

(i)  $Z_{01} = 0.55 + j 1.975 = 2.05 \angle 74.44^\circ$

(ii)  $Z_{02} = K^2 Z_{01} = (1/5)^2 (0.55 + j 1.975) = (0.022 + j 0.079)$

No-load secondary voltage =  $K V_1 = (1/5) \times 2200 = 440 \text{ V}$ ,  $I_2 = 10 \times 10^3/440 = 227.3 \text{ A}$

Full-load voltage drop as referred to secondary

$$= I_2 (R_{02} \cos \phi - X_{02} \sin \phi)$$

$$= 227.3 (0.022 \times 0.8 - 0.079 \times 0.6) = -6.77 \text{ V}$$

$$\% \text{ regn.} = -6.77 \times 100/440 = -1.54$$

Secondary terminal voltage on load =  $440 - (-6.77) = 446.77 \text{ V}$

**Example 32.44.** The corrected instrument readings obtained from open and short-circuit tests on 10-kVA, 450/120-V, 50-Hz transformer are :

O.C. test :  $V_1 = 120 \text{ V}$ ;  $I_1 = 4.2 \text{ A}$ ;  $W_1 = 80 \text{ W}$ ;  $V_1$ ,  $W_1$  and  $I_1$  were read on the low-voltage side.

S.C. test :  $V_1 = 9.65 \text{ V}$ ;  $I_1 = 22.2 \text{ A}$ ;  $W_1 = 120 \text{ W}$  - with low-voltage winding short-circuited

Compute :

- (i) the equivalent circuit (approximate) constants,
- (ii) efficiency and voltage regulation for an 80% lagging p.f. load,
- (iii) the efficiency at half full-load and 80% lagging p.f. load.

(Electrical Engineering-I, Bombay Univ. 1988)

**Solution.** It is seen from the O.C. test, that with primary open, the secondary draws a no-load current of 4.2 A. Since  $K = 120/450 = 4/15$ , the corresponding no-load primary current  $I_0 = 4.2 \times 4/15 = 1.12 \text{ A}$ .

(i) Now,  $V_1 I_0 \cos \phi_0 = 80 \therefore \cos \phi_0 = 80/450 \times 1.12 = 0.159$

$\therefore \phi_0 = \cos^{-1}(0.159) = 80.9^\circ$ ;  $\sin \phi_0 = 0.987$

$I_w = I_0 \cos \phi_0 = 1.12 \times 0.159 = 0.178 \text{ A}$  and  $I_\mu = 1.12 \times 0.987 = 1.1 \text{ A}$

$\therefore R_0 = 450/0.178 = 2530 \Omega$  and  $X_0 = 450/1.1 = 409 \Omega$

During S.C. test, instruments have been placed in primary.

$\therefore Z_{01} = 9.65/22.2 = 0.435 \Omega$

$R_{01} = 120/22.2^2 = 0.243 \Omega$

$X_{01} = \sqrt{0.435^2 - 0.243^2} = 0.361 \Omega$

The equivalent circuit is shown in Fig. 32.52.

(ii) Total approximate voltage drop as referred to primary is  $I_1 (R_{01} \cos \phi + X_{01} \sin \phi)$ .

\* Assuming  $\phi_1 = \phi_2 = \cos^{-1}(0.8)$ .

Now, full-load  $I_1 = 10,000/450 = 22.2 \text{ A}$   
 $\therefore \text{Drop} = 22.2 (0.243 \times 0.8 + 0.361 \times 0.6) = 9.2 \text{ V}$   
 Regulation  $= 9.2 \times 100/450 = 2.04\%$   
 F.L. losses  $= 80 + 120 = 200 \text{ W};$   
 F.L. output  $= 10,000 \times 0.8 = 8000 \text{ W}$   
 $\eta = 8000/8200 = 0.9757$  or **97.57%**

(iii) Half-load

Iron loss  $= 80 \text{ W}; \text{Cu loss} = (1/2)^2 \times 120 = 30 \text{ W}$   
 Total losses  $= 110 \text{ W}; \text{Output} = 5000 \times 0.8 = 4000 \text{ W}$   
 $\therefore \eta = 4000/4110 = 0.9734$  or **97.34%**

Fig. 32.52

**Example 32.45.** Consider a 20 kVA, 2200/220 V, 50 Hz transformer. The O.C./S.C. test results are as follows :

O.C. test : 220 V, 4.2 A, 148 W (l.v. side)

S.C. test : 86 V, 10.5 A, 360 W (h.v. side)

Determine the regulation at 0.8 p.f. lagging and at full load. What is the p.f. on short-circuit ?

(Elect. Machines Nagpur Univ. 1993)

**Solution.** It may be noted that O.C. data is not required in this question for finding the regulation. Since during S.C. test instruments have been placed on the h.v. side i.e. primary side.

$$\therefore Z_{01} = 86/10.5 = 8.19 \Omega; R_{01} = 360/10.5^2 = 3.26 \Omega$$

$$X_{01} = \sqrt{8.19^2 - 3.26^2} = 7.5 \Omega$$

F.L. primary current,  $I_1 = 20,000/2200 = 9.09 \text{ A}$

Total voltage drop as referred to primary  $= I_1 (R_{01} \cos \phi + X_{01} \sin \phi)$

Drop  $= 9.09 (3.26 \times 0.8 + 7.5 \times 0.6) = 64.6 \text{ V}$

% age regn.  $= 64.6 \times 100/2200 = 2.9\%$ , p.f. on short-circuit  $= R_{01}/Z_{01} = 3.26/8.19 = 0.4 \text{ lag}$

**Example 32.46.** A short-circuit test when performed on the h.v. side of a 10 kVA, 2000/400 V single phase transformer, gave the following data ; 60 V, 4 A, 100 W.

If the l.v. side is delivering full load current at 0.8 p.f. lag and at 400 V, find the voltage applied to h.v. side.

(Elect. Machines-I, Nagpur Univ. 1993)

**Solution.** Here, the test has been performed on the h.v. side i.e. primary side.

$$Z_{01} = 60/4 = 15 \Omega; R_{01} = 100/4^2 = 6.25 \Omega; X_{01} = \sqrt{15^2 - 6.25^2} = 13.63 \Omega$$

FL.  $I_1 = 10,000/2000 = 5 \text{ A}$

Total transformer voltage drop as referred to primary is

$$I_1 (R_{01} \cos \phi + X_{01} \sin \phi) = 5 (6.25 \times 0.8 + 13.63 \times 0.6) = 67 \text{ V}$$

Hence, primary voltage has to be raised from 2000 V to 2067 V in order to compensate for the total voltage drop in the transformer. In that case secondary voltage on load would remain the same as on no-load.

**Example 32.47.** A 250/500-V transformer gave the following test results :

Short-circuit test : with low-voltage winding short-circuited :

20 V; 12 A, 100 W

Open-circuit test : 250 V, 1 A, 80 W on low-voltage side.

Determine the circuit constants, insert these on the equivalent circuit diagram and calculate applied voltage and efficiency when the output is 10 A at 500 volt and 0.8 power factor lagging.

(Elect. Machines, Nagpur Univ. 1993)

**Solution. Open-circuit Test :**

$$V_1 I_0 \cos \phi_0 = 80 \quad \therefore \cos \phi_0 = 80/250 \times I = 0.32$$

$$I_w = I_0 \cos \phi_0 = I \times 0.32 = 0.32 \text{ A}, I_\mu = \sqrt{(1^2 - 0.32^2)} = 0.95 \text{ A}$$

$$R_0 = V_1 / I_w = 250/0.32 = 781.3 \Omega, X_0 = V_1 / I_\mu = 250/0.95 = 263.8 \Omega$$

The circuit is shown in Fig. 32.53 (a).

**Short-circuit Test :**

As the primary is short-circuited, all values refer to secondary winding.

Fig. 32.53 (a)

Fig. 32.53 (b)

$$\therefore R_{02} = \frac{\text{short-circuit power}}{\text{F.L. secondary current}} = \frac{100}{12^2} = 0.694 \Omega$$

$$Z_{02} = 20/12 = 1.667 \Omega; X_{02} = \sqrt{(1.667^2 - 0.694^2)} = 1.518 \Omega$$

As  $R_0$  and  $X_0$  refer to primary, hence we will transfer these values to primary with the help of transformation ratio.

$$K = 500/250 = 2 \quad \therefore R_{01} = R_{02}/K^2 = 0.694/4 = 0.174 \Omega$$

$$X_{01} = X_{02}/K^2 = 1.518/4 = 0.38 \Omega; Z_{01} = Z_{02}/K^2 = 1.667/4 = 0.417 \Omega$$

The equivalent circuit is shown in Fig. 32.53 (a).

**Efficiency**

$$\text{Total Cu loss} = I_2^2 R_{02} = 100 \times 0.694 = 69.4 \text{ W}; \text{Iron loss} = 80 \text{ W}$$

$$\text{Total loss} = 69.4 + 80 = 149.4 \text{ W} \quad \therefore \eta = \frac{5000 \times 0.8 \times 100}{4000 + 149.4} = 96.42\%$$

The applied voltage  $V_1'$  is the vector sum of  $V_1$  and  $I_1 Z_{01}$  as shown in Fig. 32.53 (b).

$$I_1 = 20 \text{ A}; I_1 R_{01} = 20 \times 0.174 = 3.84 \text{ V}; I_1 X_{01} = 20 \times 0.38 = 7.6 \text{ V}$$

Neglecting the angle between  $V_1$  and  $V_1'$ , we have

$$\begin{aligned} V_1'^2 &= OC^2 = ON^2 + NC^2 = (OM + MN)^2 + (NB + BC)^2 \\ &= (250 \times 0.8 + 3.48)^2 + (250 \times 0.6 + 7.6)^2 \\ V_1'^2 &= 203.5^2 + 157.6^2 \quad \therefore V_1' = 257.4 \text{ V} \end{aligned}$$

**Example 32.48.** A 230/230 V, 3 kVA transformer gave the following results :

O.C. Test : 230 V, 2 amp, 100 W

S.C. Test : 15 V, 13 amp, 120 W

Determine the regulation and efficiency at full load 0.80 p.f. lagging.

(Sambalpur University, 1998)

**Solution.** This is the case of a transformer with turns ratio as 1 : 1. Such a transformer is mainly required for isolation.

$$\begin{aligned} \text{Rated Current} &= \frac{3000}{230} = 13 \text{ amp} \\ \text{Cu-losses at rated load} &= 120 \text{ watts, from S.C. test} \\ \text{Core losses} &= 100 \text{ watts, from O.C. test} \\ \text{At full load, VA output} &= \mathbf{3000} \\ \text{At 0.8 lag p.f., Power output} &= 3000 \times 0.8 = 2400 \text{ watts} \\ \text{Required efficiency} &= \frac{2400}{2400 + 220} \times 100\% = 91.6\% \\ \text{From S.C. test, } Z &= \frac{15}{13} = 1.154 \text{ ohms} \\ R &= \frac{120}{15 \times 15} = 0.53 \text{ ohm, } X = \sqrt{1.154^2 - 0.53^2} = 1.0251 \text{ ohm} \\ \text{Approximate voltage regulation} &= IR \cos \phi + IX \sin \phi = 13[0.53 \times 0.8 + 1.0251 \times 0.6] \\ &= 13[0.424 + 0.615] = 13.51 \text{ volts} \end{aligned}$$

$$\text{In terms of \% , the voltage regulation} = \frac{13.51}{230} \times 100\% = \mathbf{5.874\%}$$

**Example 32.49.** A 10 kVA, 500/250 V, single-phase transformer has its maximum efficiency of 94% when delivering 90% of its rated output at unity p.f. Estimate its efficiency when delivering its full-load output at p.f. of 0.8 lagging. (Nagpur University, November 1998)

**Solution.** Rated output at unity p.f. = 10000 W. Hence, 90% of rated output = 9,000 W

$$\text{Input with 94\% efficiency} = 9000/0.94 \text{ W}$$

$$\text{Losses} = 9000((1/0.94) - 1) = 574 \text{ W}$$

At maximum efficiency, variable copper-loss = constant = Core loss = 574/2 = 287 W

At rated current, Let the copper-loss =  $P_c$  watts

At 90% load with unity p.f., the copper-loss is expressed as  $0.90^2 \times P_c$ .

$$\text{Hence, } P_c = 287/0.81 = 354 \text{ W}$$

(b) Output at full-load, 0.8 lag p.f. = 10,000 × 0.80 = 8000 W

At the corresponding load, Full Load copper-loss = 354 W

$$\text{Hence, efficiency} = 8000/(8000 + 354 + 287) = 0.926 = \mathbf{92.6\%}$$

**Example 32.50.** Resistances and Leakage reactance of 10 kVA, 50 Hz, 2300/230 V single phase distribution transformer are  $r_1 = 3.96$  ohms,  $r_2 = 0.0396$  ohms,  $x_1 = 15.8$  ohms,  $x_2 = 0.158$  ohm. Subscript 1 refers to HV and 2 to LV winding (a) transformer delivers rated kVA at 0.8 p.f. Lagging to a load on the L.V. side. Find the H.V. side voltage necessary to maintain 230 V across Load-terminals. Also find percentage voltage regulation. (b) Find the power-factor of the rated load-current at which the voltage regulation will be zero, hence find the H.V. side voltage.

(Nagpur University, November 1997)

**Solution.** (a) Rated current on L.V. side = 10,000/230 = 43.5 A. Let the total resistance and total leakage reactance be referred to L.V. side. Finally, the required H.V. side voltage can be worked out after transformation.

$$\begin{aligned} \text{Total resistance, } r &= r_1' + r_2 = 3.96 \times (230/2300)^2 + 0.0396 \\ &= 0.0792 \text{ ohms} \end{aligned}$$

$$\begin{aligned} \text{Total leakage-reactance, } x &= x_1' + x_2 = 15.8 \times (230/2300)^2 + 0.158 \\ &= 0.316 \text{ ohm} \end{aligned}$$

For purpose of calculation of voltage-magnitudes, approximate formula for voltage regulation can be used. For the present case of 0.8 lagging p.f.

$$\begin{aligned} V_1' &= V_2 + I [r \cos \phi + x \sin \phi] \\ &= 230 + 43.5 [(0.0792 \times 0.8) + (0.316 \times 0.6)] \\ &= 230 + 43.5 [0.0634 + 0.1896] = 230 + 11 = 241 \text{ volts} \end{aligned}$$

Hence,  $V_1 = 241 \times (2300/230) = 2410 \text{ volts.}$

It means that H.V. side terminal voltage must be 2410 for keeping 230 V at the specified load.

(b) Approximate formula for voltage regulation is :  $V_1' - V_2 = I [r \cos \phi \pm x \sin \phi]$

With Lagging p.f., +ve sign is retained. With leading power-factor, the -ve sign is applicable. For the voltage-regulation to be zero, only leading P.f. condition can prevail.

Thus,  $r \cos \phi - x \sin \phi = 0$

or  $\tan \phi = r/x = 0.0792/0.316 = 0.25$

or  $\phi = 14^\circ, \cos \phi = 0.97 \text{ leading}$

Corresponding  $\sin \phi = \sin 14^\circ = 0.243$

H.V. terminal voltage required is 2300 V to maintain 230 V at Load, since Zero regulation condition is under discussion.

**Example 32.51.** A 5 kVA, 2200/220 V, single-phase transformer has the following parameters.

H.V. side :  $r_1 = 3.4 \text{ ohms}, x_1 = 7.2 \text{ ohms}$

L.V. side :  $r_2 = 0.028 \text{ ohms}, x_2 = 0.060 \text{ ohms}$

Transformer is made to deliver rated current at 0.8 lagging P.f. to a load connected on the L.V. side. If the load voltage is 220 V, calculate the terminal voltage on H.V. side

(Neglect the exciting current). (Rajiv Gandhi Technical University, Bhopal, Summer 2001)

**Solution.** Calculations may be done referring all the parameters the L.V. side first. Finally, the voltage required on H.V. side can be obtained after transformation.

Rated current ref. to L.V. side =  $5000/220 = 22.73 \text{ A}$

Total winding resistance ref. to L.V. side =  $r_1' + r_2 = (220/2200)^2 \times 3.4 + 0.028$

Total winding-leakage-reactance ref. to L.V. side =  $x_1' + x_2$   
 $= (220/2200)^2 \times 7.2 + 0.060 = 0.132 \text{ ohm}$

Fig. 32.53(c)

In the phasor diagram of Fig. 32.53 (c).

$QA = V_2 = 220 \text{ volts}, I = 22.73 \text{ A at lagging phase angle of } 36.87^\circ$

$AB = Ir, AD = Ir \cos \phi = 22.73 \times 0.062 \times 0.80 = 1.127 \text{ V}$

$DC = Ix \sin \phi = 22.73 \times 0.132 \times 0.60 = 1.80 \text{ V}$

$$\begin{aligned}
 OC &= 220 + 1.127 + 1.80 = 222.93 \text{ volts} \\
 BD &= Ir \sin \phi = 0.85 \text{ V} \\
 B'F &= x \cos \phi = 2.40 \text{ V} \\
 CF &= 2.40 - 0.85 = 1.55 \text{ V} \\
 V_1' &= OF = (222.93^2 + 1.55^2)^{0.50} = 222.935 \text{ volts}
 \end{aligned}$$

Required terminal voltage of H.V. side =  $V_1 = 222.935 \times (2200/220) = 2229.35$  volts

[Note. In approximate and fast calculations,  $CF$  is often ignored for calculation of magnitude of  $V_1'$ . The concerned expression is :  $V_1' = V_2 + Ir \cos \phi + Ix \sin \phi$ , for lagging P.f.]

**Example 32.52.** A 4-kVA, 200/400 V, single-phase transformer takes 0.7 amp and 65 W on Open-circuit. When the low-voltage winding is short-circuited and 15 V is applied to the high-voltage terminals, the current and power are 10 A and 75 W respectively. Calculate the full-load efficiency at unity power factor and full-load regulation at 0.80 power-factor lagging.

(Nagpur University April 1999)

**Solution.** At a load of 4 kVA, the rated currents are :

$$\begin{aligned}
 \text{L.V. side:} & \quad 4000/200 = 20 \text{ amp} \\
 \text{And H.V. side:} & \quad 4000/400 = 10 \text{ amp} \\
 \text{From the test data, full-load copper-loss} &= 75 \text{ W} \\
 \text{And constant core-loss} &= 65 \text{ W}
 \end{aligned}$$

$$\begin{aligned}
 \text{From S.C. test,} & \quad Z = 15/10 = 1.5 \text{ ohms} \\
 & \quad R = 75/100 = 0.75 \text{ ohm}
 \end{aligned}$$

$$\text{Hence} \quad x = \sqrt{1.5^2 - 0.75^2} = 1.30 \text{ ohms}$$

All these series-parameters are referred to the H.V. side, since the S.C. test has been conducted from H.V. side.

$$\begin{aligned}
 \text{Full-load efficiency at unity p.f.} &= 4000 / (4000 + 65 + 75) \\
 &= 0.966 = 96.6\%
 \end{aligned}$$

$$\begin{aligned}
 \text{Full load voltage regulation at 0.80 lagging p.f.} & \\
 &= Ir \cos \phi + Ix \sin \phi \\
 &= 10 (0.75 \times 0.80 + 1.30 \times 0.60) = 16.14 \text{ Volts}
 \end{aligned}$$

Thus, due to loading, H.V. side voltage will drop by 16.14 volts (*i.e.* terminal voltage for the load will be 383.86 volts), when L.V. side is energized by 200-V source.

### 32.25. Percentage Resistance, Reactance and Impedance

These quantities are usually measured by the voltage drop at full-load current expressed as a percentage of the normal voltage of the winding on which calculations are made.

(i) Percentage resistance at full-load

$$\begin{aligned}
 \% R &= \frac{I_1 R_{01}}{V_1} \times 100 = \frac{I_1^2 R_{01}}{V_1 I_1} \times 100 \\
 &= \frac{I_2^2 R_{02}}{V_2 I_2} \times 100 = \% \text{ Cu loss at full-load} \\
 \% R &= \% \text{ Cu loss} = v_r \qquad \dots \text{Art.32.16}
 \end{aligned}$$

(ii) Percentage reactance at full-load

$$\% X = \frac{I_1 X_{01}}{V_1} \times 100 = \frac{I_2 X_{02}}{V_2} \times 100 = v_x$$

(iii) Percentage impedance at full-load

$$\% Z = \frac{I_1 Z_{01}}{V_1} \times 100 = \frac{I_2 Z_{02}}{V_2} \times 100$$

(iv) 
$$\% Z = \sqrt{(\% R^2 + \% X^2)}$$

It should be noted from above that the reactances and resistances in ohm can be obtained thus :

$$R_{01} = \frac{\% R \times V_1}{100 \times I_1} = \frac{\% \text{ Cu loss} \times V_1}{100 \times I_1} ; \text{ Similarly } R_{02} = \frac{\% R \times V_2}{100 \times I_2} = \frac{\% \text{ Cu loss} \times V_2}{100 \times I_2}$$

$$X_{01} = \frac{\% X \times V_1}{100 \times I_1} = \frac{v_z \times V_1}{100 \times I_1} ; \text{ Similarly } X_{02} = \frac{\% X \times V_2}{100 \times I_2} = \frac{v_x \times V_2}{100 \times I_2}$$

It may be noted that percentage resistance, reactance and impedance have the same value whether referred to primary or secondary.

**Example 32.53.** A 3300/230 V, 50-kVA, transformer is found to have impedance of 4% and a Cu loss of 1.8% at full-load. Find its percentage reactance and also the ohmic values of resistance, reactance and impedance as referred to primary. What would be the value of primary short-circuit current if primary voltage is assumed constant ?

**Solution.** 
$$\% X = \sqrt{(\% Z^2 - \% R^2)} = \sqrt{(4^2 - 1.8^2)} = 3.57\% (\because \text{Cu loss} = \% R)$$

Full load  $I_1 = 50,000/3300 = 15.2 \text{ A}$  (assuming 100% efficiency). Considering primary winding, we have

$$\% R = \frac{R_{01} I_1 \times 100}{V_L} = 1.8 \quad \therefore R_{01} = \frac{1.8 \times 3300}{100 \times 15.2} = 3.91 \Omega$$

Similarly 
$$\% X = \frac{X_{01} I_1 \times 100}{V_1} = 3.57 \quad \therefore X_{01} = \frac{3.57 \times 3300}{100 \times 15.2} = 7.76 \Omega$$

Similarly 
$$Z_{01} = \frac{4 \times 3300}{100 \times 15.2} = 8.7 \Omega$$

Now 
$$\frac{\text{Short-circuit current}^*}{\text{Full load current}} = \frac{100}{4} \quad \therefore \text{S.C. current} = 15.2 \times 25 = 380 \text{ A}$$

**Example 32.54.** A 20-kVA, 2200/220-V, 50-Hz distribution transformer is tested for efficiency and regulation as follows :

O.C. test : 220 V      4.2 A, 148 W      -l.v side

S.C. test : 86 V      10.5 A, 360 W      -l.v side

Determine (a) core loss (b) equivalent resistance referred to primary (c) equivalent resistance referred to secondary (d) equivalent reactance referred to primary (e) equivalent reactance referred to secondary (f) regulation of transformer at 0.8 p.f. lagging current (g) efficiency at full-load and half the full-load at 0.8 p.f. lagging current.

**Solution.** (a) As shown in Art 32.9, no-load primary input is practically equal to the core loss. Hence, core loss as found from no-load test, is **148 W**.

(b) From S.C. test, 
$$R_{01} = 360/10.5^2 = 3.26 \Omega$$

(c) 
$$R_{02} = K^2 R_{01} = (220/2200)^2 \times 3.26 = 0.0326 \Omega$$

\* Short circuit

$$I_{SC} = \frac{V_1}{Z_{01}} \quad \text{Now, } Z_{01} = \frac{V_1 \times \% Z}{100 \times I_1}$$

$$I_{SC} = \frac{V_1 \times 100 \times I_1}{V_1 \times \% Z} = \frac{100 \times I_1}{\% Z} \quad \therefore \frac{I_{SC}}{I_1} = \frac{100}{\% Z}$$

$$(d) \quad Z_{10} = \frac{V_{SC}}{I_{SC}} = \frac{86}{10.5} = 8.19 \, \Omega$$

$$X_{01} = \sqrt{(8.19^2 - 3.26^2)} = 7.51 \, \Omega$$

$$(e) \quad X_{02} = K^2 X_{01} = (220/2200)^2 \times 7.51 = 0.0751 \, \Omega$$

(f) We will use the definition of regulation as given in Art. 32.24 (3).

We will find the rise in primary voltage necessary to maintain the output terminal voltage constant from no-load to full-load.

$$\text{Rated primary current} = 20,000/2200 = 9.1 \, \text{A}$$

$$V_1' = \sqrt{[2200 \times 0.8 + 9.1 \times 3.26]^2 + (2200 \times 0.6 + 9.1 \times 7.51)^2} = 2265 \, \text{V}$$

$$\therefore \quad \% \text{ regn} = \frac{2265 - 2200}{2200} \times 100 = 2.95\%$$

We would get the same result by working in the secondary. Rated secondary current = 91 A.

$${}_0V_2 = \sqrt{(220 \times 0.8 + 91 \times 0.0326)^2 + (220 \times 0.6 + 91 \times 0.0751)^2} = 226.5 \, \text{V}$$

$$\therefore \quad \% \text{ regns.} = \frac{226.5 - 220}{220} \times 100 = 2.95\%$$

(g) Core loss = 1.48 W. It will be the same for all loads.

Cu loss at full load =  $I_1^2 R_{01} = 9.1^2 \times 3.26 = 270 \, \text{W}$

Cu loss at half full-load =  $4.55^2 \times 3.26 = 67.5 \, \text{W}$  (or F.L. Cu loss/4)

$$\therefore \quad \eta \text{ at full-load} = \frac{22,000 \times 0.8 \times 100}{20,000 \times 0.8 + 148 + 270} = 97.4\%$$

$$\therefore \quad \eta \text{ at half-load} = \frac{10,000 \times 0.8 \times 100}{10,000 \times 0.8 + 148 + 67.5} = 97.3\%$$

**Example 32.55.** Calculate the regulation of a transformer in which the ohmic loss is 1% of the output and the reactance drop is 5% of the voltage, when the power factor is (i) 0.80 Lag (ii) unity (iii) 0.80 Leading. (Madras University, 1997)

**Solution.** When 1% of output is the ohmic loss, p.u. resistance of the transformer,  $\epsilon_r = 0.01$

When 5% is the reactance drop, p.u. reactance of the transformer  $\epsilon_x = 0.05$

(i) Per Unit regulation of the transformer at full-load, 0.8 Lagging p.f.

$$= 0.01 \times \cos \phi + 0.05 \times \sin \phi = 0.01 \times 0.8 + 0.05 \times 0.6 = 0.038 \text{ or } 3.8\%$$

(ii) Per Unit regulation at unity p.f. =  $0.01 \times 1 = 0.01$  or 1%

(iii) Per Unit regulation at 0.8 Leading p.f. =  $0.01 \times 0.8 - 0.05 \times 0.6 = -0.022$  or -2.2%

**Example 32.56.** The maximum efficiency of a 500 kVA, 3300/500 V, 50 Hz, single phase transformer is 97% and occurs at 3/4<sup>th</sup> full-load u.p.f. If the impedance is 10% calculate the regulation at fullload, 0.8 p.f. Lag. (Madurai Kamraj University, November 1997)

**Solution.** At unity p.f. with 3/4<sup>th</sup> full load, the output of the transformer

$$= 500 \times 0.75 \times 1 \, \text{kW} = 375 \, \text{kW}$$

$$0.97 = \frac{375}{375 + 2 P_i}$$

where  $P_i$  = core loss in kW, at rated voltage.

At maximum efficiency,  $x^2 P_c = P_i$

$$(0.75)^2 P_c = P_i$$

where  $x = 0.75$ , i.e. 3/4<sup>th</sup> which is the fractional loading of the transformer

$P_c$  = copper losses in kW, at rated current

$$P_i = \frac{1}{2} \left\{ (375) \times \left( \frac{1}{0.97} - 1 \right) \right\} = \frac{1}{2} \times 375 \times \frac{3}{97} = 5.8 \text{ kW}$$

$$P_c = 5.8 / (0.75)^2 = 10.3 \text{ kW}$$

$$\text{Full load current in primary (H.V.) winding} = \frac{500 \times 1000}{3300} = \mathbf{151.5 \text{ amp}}$$

Total winding resistance ref. to primary

$$= \frac{10.3 \times 1000}{(151.5)^2} = 0.44876 \text{ ohm}$$

$$\epsilon_r = \% \text{ resistance} = \frac{151.5 \times 0.44876}{3300} \times 100 \% = \mathbf{2.06\%}$$

$$\epsilon_z = \% \text{ Impedance} = 10\%$$

$$\epsilon_x = \% \text{ reactance} = \sqrt{100 - 4.244} = \mathbf{9.7855\%}$$

By Approximate formula at 0.8 p.f. lag

$$\begin{aligned} \% \text{ regulation} &= \epsilon_r \cos \phi + \epsilon_x \sin \phi \\ &= 2.06 \times 0.8 + 9.7855 \times 0.6 \\ &= 1.648 + 5.87 = \mathbf{7.52\%} \end{aligned}$$

**Example 32.57.** A transformer has copper-loss of 1.5% and reactance-drop of 3.5% when tested at full-load. Calculate its full-load regulation at (i) u.p.f. (ii) 0.8 p.f. Lagging and (iii) 0.8 p.f. Leading. (Bharathithasan Univ. April 1997)

**Solution.** The test-data at full-load gives following parameters :

$$\text{p.u. resistance} = 0.015, \quad \text{p.u. reactance} = 0.035$$

(i) Approximate Voltage – Regulation at unity p.f. full load

$$\begin{aligned} &= 0.015 \cos \phi + 0.035 \sin \phi \\ &= 0.015 \text{ per unit} = \mathbf{1.5\%} \end{aligned}$$

(ii) Approximate Voltage – Regulation at 0.80 Lagging p.f.

$$= (0.015 \times 0.8) + (0.035 \times 0.6) = 0.033 \text{ per unit} = \mathbf{3.3\%}$$

(iii) Approximate Voltage Regulation at 0.8 leading p.f.

$$\begin{aligned} &= I_r \cos \phi - I_x \sin \phi \\ &= (0.015 \times 0.8) - (0.035 \times 0.6) = -0.009 \text{ per unit} = \mathbf{-0.9\%} \end{aligned}$$

### 32.26. Kapp Regulation Diagram

It has been shown that secondary terminal voltage falls as the load on the transformer is increased when p.f. is lagging and it increases when the power factor is leading. In other words, secondary terminal voltage not only depends on the load but on power factor also (Art. 32.16). For finding the voltage drop (or rise) which is further used in determining the regulation of the transformer, a graphical construction is employed which was proposed by late Dr. Kapp.

For drawing Kapp regulation diagram, it is necessary to know the equivalent resistance and reactance as referred to secondary *i.e.*  $R_{02}$  and  $X_{02}$ . If  $I_2$  is the secondary load current, then secondary terminal voltage on load  $V_2$ , is obtained by subtracting  $I_2 R_{02}$  and  $I_2 X_{02}$  voltage drops vectorially from secondary no-load voltage  ${}_0V_2$ .

Now,  ${}_0V_2$  is constant, hence it can be represented by a circle of constant radius  $OA$  as in Fig. 32.54. This circle is known as no-load or open-circuit e.m.f. circle. For a given load,  $OI_2$  represents the load current and is taken as the reference vector,  $CB$  represents  $I_2 R_{02}$  and is parallel to  $OI_2$ ,  $AB$  represents  $I_2 X_{02}$  and is drawn at right angles to  $CB$ . Vector  $OC$  obviously represents  $I_2 X_{02}$  and is drawn at right

angles to  $CB$ . Vector  $OC$  obviously represents secondary terminal voltage  $V_2$ . Since  $I_2$  is constant, the drop triangle  $ABC$  remains constant in size. It is seen that end point  $C$  of  $V_2$  lies on another circle whose centre is  $O'$ . This point  $O'$  lies at a distance of  $I_2 X_{02}$  vertically below the point  $O$  and a distance of  $I_2 R_{02}$  to its left as shown in Fig. 32.54.

Suppose it is required to find the voltage drop on full-load at a lagging power factor of  $\cos \phi$ , then a radius  $OLP$  is drawn inclined at an angle of  $\phi$  with  $OX$ .  $LM = I_2 R_{02}$  and is drawn horizontal  $MN = I_2 X_{02}$  and is drawn perpendicular to  $LM$ . Obviously,  $ON$  is no-load voltage  ${}_0V_2$ . Now,  $ON = OP = {}_0V_2$ . Similarly,  $OL$  is  $V_2$ . The voltage drop =  $OP - OL = LP$ .

Fig. 32.54

$$\text{Hence, percentage regulation 'down' is} = \frac{OP - OL}{OP} \times 100 = \frac{LP}{OP} \times 100$$

It is seen that for finding voltage drop, triangle  $LMN$  need not be drawn, but simply the radius  $OLP$ .

The diagram shows clearly how the secondary terminal voltage falls as the angle of lag increases. Conversely, for a leading power factor, the fall in secondary terminal voltage decreases till for an angle of  $\phi_0$  leading, the fall becomes zero; hence  $V_2 = {}_0V_2$ . For angles greater than  $\phi_0$ , the secondary terminal voltage  $V_2$  becomes greater than  ${}_0V_2$ .

The Kapp diagram is very helpful in determining the variation of regulation with power factor but it has the disadvantage that since the lengths of the sides of the impedance triangle are very small as compared to the radii of the circles, the diagram has to be drawn on a very large scale, if sufficiently accurate results are desired.

### 32.27. Sumpner of Back-to-Back Test

This test provides data for finding the regulation, efficiency and heating under load conditions and is employed only when two similar transformers are available. One transformer is loaded on the other and both are connected to supply. The power taken from the supply is that necessary for supplying the losses of both transformers and the negligibly small loss in the control circuit.

As shown in Fig. 32.55, primaries of the two transformers are connected in parallel across the same a.c. supply. With switch  $S$  open, the wattmeter  $W_1$  reads the core loss for the two transformers.

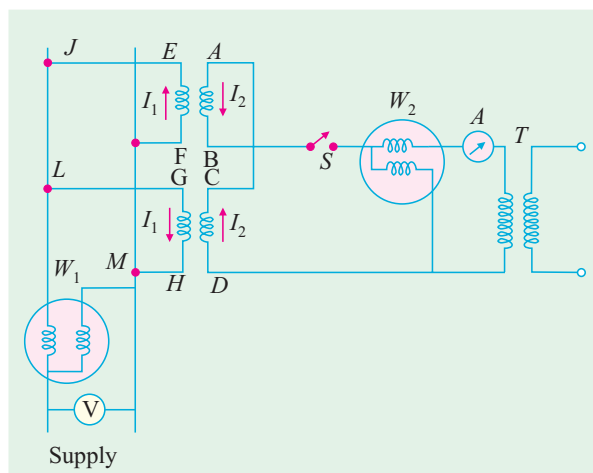

Fig. 32.55

The secondaries are so connected that their potentials are in opposition to each other. This would so if  $V_{AB} = V_{CD}$  and  $A$  is joined to  $C$  whilst  $B$  is joined to  $D$ . In that case, there would be no secondary current flowing around the loop formed by the two secondaries.  $T$  is an auxiliary low-voltage transformer which can be adjusted to give a variable voltage and hence current in the secondary loop circuit. By proper adjustment of  $T$ , full-load secondary current  $I_2$  can be made to flow as shown. It is seen, that  $I_2$  flows from  $D$  to  $C$  and then from  $A$  to  $B$ . Flow of  $I_1$  is confined to the loop  $FEJLGHMF$  and it does not pass through  $W_1$ . Hence,  $W_1$  continues to read the core loss and  $W_2$  measures full-load Cu loss (or at any other load current value  $I_2$ ). Obviously, the power taken in is twice the losses of a single transformer.

**Example 32.58.** Two similar 250-kVA, single-phase transformers gave the following results when tested by back-to-back method :

Mains wattmeter,  $W_1 = 5.0 \text{ kW}$

Primary series circuit wattmeter,  $W_2 = 7.5 \text{ kW}$  (at full-load current).

Find out the individual transformer efficiencies at 75% full-load and 0.8 p.f. lead.

(Electrical Machines-III, Gujarat Univ. 1986)

**Solution.** Total losses for both transformers =  $5 + 7.5 = 12.5 \text{ kW}$

F.L. loss for each transformer =  $12.5/2 = 6.25 \text{ kW}$

$$\text{Copper-loss at 75\% load} = \left(\frac{3}{4}\right)^2 \times \frac{7.5}{2} \text{ kW} = 2.11 \text{ kW}$$

Output of each transformer at 75% F.L. and 0.8 p.f. =  $(250 \times 0.75) \times 0.8 = 150 \text{ kW}$

$$\eta = \frac{150}{150 + 2.5 + 2.11} = 97\%$$

### 32.28. Losses in a Transformer

In a static transformer, there are no friction or windage losses. Hence, the only losses occurring are :

(i) **Core or Iron Loss :** It includes both hysteresis loss and eddy current loss. Because the core flux in a transformer remains practically constant for all loads (its variation being

Typical 75kVA Transformer Losses vs. Load

1 to 3% from no-load to full-load). The core loss is practically the same at all loads.

Hysteresis loss  $W_h = \eta B_{\text{max}}^{1.6} f V$  watt; eddy current loss  $W_e = PB_{\text{max}}^2 f^2 t^2$  watt

These losses are minimized by using steel of high silicon content for the core and by using very thin

laminations. Iron or core loss is found from the *O.C.* test. *The input of the transformer when on no-load measures the core loss.*

(ii) **Copper loss.** This loss is due to the ohmic resistance of the transformer windings. Total Cu loss =  $I_1^2 R_1 + I_2^2 R_2 = I_1^2 R_{01} + I_2^2 R_{02}$ . It is clear that Cu loss is proportional to (current)<sup>2</sup> or kVA<sup>2</sup>. In other words, Cu loss at half the full-load is one-fourth of that at full-load.

The value of Cu loss is found from the short-circuit test (Art. 32.22).

### 32.29. Efficiency of a Transformer

As is the case with other types of electrical machines, the efficiency of a transformer at a particular load and power factor is defined as the output divided by the input—the two being measured in the same units (either watts or kilowatts).

$$\text{Efficiency} = \frac{\text{Output}}{\text{Input}}$$

But a transformer being a highly efficient piece of equipment, has very small loss, hence it is impractical to try to measure transformer efficiency by measuring input and output. These quantities are nearly of the same size. A better method is to determine the losses and then to calculate the efficiency from ;

$$\text{Efficiency} = \frac{\text{Output}}{\text{Output} + \text{losses}} = \frac{\text{Output}}{\text{Output} + \text{Cu loss} + \text{iron loss}}$$

or

$$\eta = \frac{\text{Input} - \text{Losses}}{\text{Input}} = 1 - \frac{\text{losses}}{\text{Input}}$$

It may be noted here that efficiency is based on power output in watts and not in volt-amperes, although losses are proportional to VA. Hence, at any volt-ampere load, the efficiency depends on power factor, being maximum at a power factor of unity.

Efficiency can be computed by determining core loss from no-load or open-circuit test and Cu loss from the short-circuit test.

### 32.30. Condition for Maximum Efficiency

$$\text{Cu loss} = I_1^2 R_{01} \quad \text{or} \quad I_2^2 R_{02} = W_{cu}$$

$$\text{Iron loss} = \text{Hysteresis loss} + \text{Eddy current loss} = W_h + W_e = W_i$$

Considering primary side,

$$\text{Primary input} = V_1 I_1 \cos \phi_1$$

$$\begin{aligned} \eta &= \frac{V_1 I_1 \cos \phi_1 - \text{losses}}{V_1 I_1 \cos \phi_1} = \frac{V_1 I_1 \cos \phi_1 - I_1^2 R_{01} - W_i}{V_1 I_1 \cos \phi_1} \\ &= 1 - \frac{I_1 R_{01}}{V_1 \cos \phi_1} - \frac{W_i}{V_1 I_1 \cos \phi_1} \end{aligned}$$

Differentiating both sides with respect to  $I_1$ , we get

$$\frac{d\eta}{dI_1} = 0 - \frac{R_{01}}{V_1 \cos \phi_1} + \frac{W_i}{V_1 I_1^2 \cos \phi_1}$$

For  $\eta$  to be maximum,  $\frac{d\eta}{dI_1} = 0$ . Hence, the above equation becomes

$$\frac{R_{01}}{V_1 \cos \phi_1} = \frac{W_i}{V_1 I_1^2 \cos \phi_1} \quad \text{or} \quad W_i = I_1^2 R_{01} \quad \text{or} \quad I_2^2 R_{02}$$

or

$$\text{Cu loss} = \text{Iron loss}$$

The output current corresponding to maximum efficiency is  $I_2 = \sqrt{(W_i/R_{02})}$ .

It is this value of the output current which will make the Cu loss equal to the iron loss. By proper design, it is possible to make the maximum efficiency occur at any desired load.

**Note. (i)** If we are given iron loss and full-load Cu loss, then the load at which two losses would be equal (i.e. corresponding to maximum efficiency) is given by

$$= \text{Full load} \times \sqrt{\left(\frac{\text{Iron loss}}{\text{F.L. Cu loss}}\right)}$$

In Fig. 32.56, Cu losses are plotted as a percentage of power input and the efficiency curve as deduced from these is also shown. It is obvious that the point of intersection of the Cu and iron loss curves gives the point of maximum efficiency. It would be seen that the efficiency is high and is practically constant from 15% full-load to 25% overload.

Fig. 32.56

(ii) The efficiency at any load is given by

$$\eta = \frac{x \times \text{full-load kVA} \times \text{p.f.}}{(x \times \text{full-load kVA} \times \text{p.f.}) + W_{cu} + W_i} \times 100$$

where  $x$  = ratio of actual to full-load kVA

$W_i$  = iron loss in kW ;  $W_{cu}$  = Cu loss in kW.

**Example 32.59.** In a 25-kVA, 2000/200 V, single-phase transformer, the iron and full-load copper losses are 350 and 400 W respectively. Calculate the efficiency at unity power factor on (i) full load (ii) half full-load.

(Elect. Engg. & Electronic, Bangalore Univ. 1990 and Similar example in U.P. Technical University 2001)

**Solution. (i) Full-load Unity p.f.**

$$\text{Total loss} = 350 + 400 = 750 \text{ W}$$

$$\text{F.L. output at u.p.f.} = 25 \times 1 = 25 \text{ kW} ; \eta = 25/25.75 = 0.97 \text{ or } 97\%$$

(ii) Half F.L. Unity p.f.

Cu loss =  $400 \times (1/2)^2 = 100 \text{ W}$ . Iron loss remains constant at 350 W, Total loss =  $100 + 350 = 450 \text{ W}$ .

Half-load output at u.p.f. = 12.5 kW

$$\therefore \eta = 12.5/(12.5 + 0.45) = 96.52\%$$

**Example 32.60.** If  $P_1$  and  $P_2$  be the iron and copper losses of a transformer on full-load, find the ratio of  $P_1$  and  $P_2$  such that maximum efficiency occurs at 75% full-load.

(Elect. Machines AMIE Sec. B, Summer 1992)

**Solution.** If  $P_2$  is the Cu loss at full-load, its value at 75% of full-load is  $= P_2 \times (0.75)^2 = 9P_2/16$ . At maximum efficiency, it equals the iron loss  $P_1$  which remains constant throughout. Hence, at maximum efficiency.

$$P_1 = 9P_2/16 \text{ or } P_1/P_2 = 9/16.$$

**Example 32.61.** A 11000/230 V, 150-kVA, 1-phase, 50-Hz transformer has core loss of 1.4 kW and F.L. Cu loss of 1.6 kW. Determine

(i) the kVA load for max. efficiency and value of max. efficiency at unity p.f.

(ii) the efficiency at half F.L. 0.8 p.f. leading (Basic Elect. Machine, Nagpur Univ. 1993)

**Solution. (i)** Load kVA corresponding to maximum efficiency is

$$= \text{F.L. kVA} \times \sqrt{\frac{\text{Iron loss}}{\text{F.L. Cu loss}}} = 250 \times \sqrt{\frac{1.6}{1.4}} = 160 \text{ kVA}$$

Since Cu loss equals iron loss at maximum efficiency, total loss = 1.4 + 1.4 = 2.8 kW ;  
output = 160 × 1 = 160 kW

$$\eta_{max} = 160/162.8 = 0.982 \text{ or } \mathbf{98.2\%}$$

**(ii)** Cu loss at half full-load =  $1.6 \times (1/2)^2 = 0.4 \text{ kW}$  ; Total loss = 1.4 + 0.4 = 1.8 kW

Half F.L. output at 0.8 p.f. =  $(150/2) \times 0.8 = 60 \text{ kW}$

∴ Efficiency =  $60/(60 + 1.8) = 0.97$  or **97%**

**Example 32.62.** A 5-kVA, 2,300/230-V, 50-Hz transformer was tested for the iron losses with normal excitation and Cu losses at full-load and these were found to be 40 W and 112 W respectively. Calculate the efficiencies of the transformer at 0.8 power factor for the following kVA outputs :

1.25                  2.5                  3.75                  5.0                  6.25                  7.5

Plot efficiency vs kVA output curve.

**(Elect. Engg. -I, Bombay Univ. 1987)**

**Solution.** F.L. Cu loss = 112 W ; Iron loss = 40 W

**(i)** Cu loss at 1.25 kVA =  $112 \times (1.25/5)^2 = 7 \text{ W}$

Total loss = 40 + 7 = 47 W    Output =  $1.25 \times 0.8 = 1 \text{ kW} = 1,000 \text{ W}$

$$\eta = 100 \times 1,000/1,047 = \mathbf{95.51\%}$$

**(ii)** Cu loss at 2.5 kVA =  $112 \times (2.5/5)^2 = 28 \text{ W}$

Total loss = 40 + 28 = 68 W

Output =  $2.5 \times 0.8 = 2 \text{ kW}$

$$\eta = 2,000 \times 100/2,068 = \mathbf{96.71\%}$$

**(iii)** Cu loss at 3.75 kVA

$$= 112 \times (3.75/5)^2 = 63 \text{ W}$$

Total loss = 40 + 63 = 103 W

$$\eta = 3,000 \times 100/3,103 = \mathbf{96.68\%}$$

**(iv)** Cu loss at 5 kVA

$$= 112 \text{ W}$$

Total loss = 152 W = 0.152 kW

Output =  $5 \times 0.8 = 4 \text{ kW}$

$$\eta = 4 \times 100/4.142 = \mathbf{96.34\%}$$

**(v)** Cu loss at 6.25 kVA

$$= 112 \times (6.25/5)^2 = 175 \text{ W}$$

Total loss = 125 W = 0.125 kW ; Output =  $6.25 \times 0.8 = 5 \text{ kW}$

$$\eta = 5 \times 100/5.215 = \mathbf{95.88\%}$$

**(vi)** Cu loss at 7.5 kVA =  $112 \times (7.5/5)^2 = 252 \text{ W}$

Total loss = 292 W = 0.292 kW ; Output =  $7.5 \times 0.8 = 6 \text{ kW}$

$$\eta = 6 \times 100/6.292 = \mathbf{95.36\%}$$

The curve is shown in Fig. 32.57.

**Fig. 32.57**

**Example 32.63.** A 200-kVA transformer has an efficiency of 98% at full load. If the max. efficiency occurs at three quarters of full-load, calculate the efficiency at half load. Assume negligible magnetizing current and p.f. 0.8 at all loads. **(Elect. Technology Punjab Univ. Jan. 1991)**

**Solution.** As given, the transformer has a F.L. efficiency of 98 % at 0.8 p.f.

$$\text{F.L. output} = 200 \times 0.8 = 160 \text{ kW} ; \text{F.L. input} = 160/0.98 = 163.265 \text{ kW}$$

$$\text{F.L. losses} = 163.265 - 160 = 3.265 \text{ kW}$$

This loss consists of F.L. Cu loss  $x$  and iron loss  $y$ .

$$\therefore x + y = 3.265 \text{ kW} \quad \dots(i)$$

It is also given that  $\eta_{max}$  occurs at three quarters of full-load when Cu loss becomes equal to iron loss.

$$\therefore \text{Cu loss at 75 \% of F.L.} = x (3/4)^2 = 9x/16$$

$$\text{Since } y \text{ remains constant, hence } 9x/16 = y \quad \dots(ii)$$

$$\text{Substituting the value of } y \text{ in Eqn. (i), we get } x + 9x/16 = 3265 \text{ or } x = 2090 \text{ W; } y = 1175 \text{ W}$$

**Half-load Unity p.f.**

$$\text{Cu loss} = 2090 \times (1/2)^2 = 522 \text{ W} ; \text{total loss} = 522 + 1175 = 1697 \text{ W}$$

$$\text{Output} = 100 \times 0.8 = 80 \text{ kW} ; \eta = 80/81.697 = 0.979 \text{ or } \mathbf{97.9 \%}$$

**Example 32.64.** A 25-kVA, 1-phase transformer, 2,200 volts to 220 volts, has a primary resistance of 1.0  $\Omega$  and a secondary resistance of 0.01  $\Omega$ . Find the equivalent secondary resistance and the full-load efficiency at 0.8 p.f. if the iron loss of the transformer is 80% of the full-load Cu loss.

(Elect. Technology, Utkal Univ. 1998)

**Solution.**  $K = 220/2,200 = 1/10$  ;  $R_{02} = R_2 + K^2 R_1 = 0.01 + 1/100 = \mathbf{0.02 \Omega}$

$$\text{Full-load } I_2 = 25,000/220 = 113.6 \text{ A} ; \text{F.L. Cu loss} = I_2^2 R_{02} = 113.6^2 \times 0.02 = 258 \text{ W.}$$

$$\text{Iron loss} = 80\% \text{ of } 258 = 206.4 \text{ W} ; \text{Total loss} = 258 + 206.4 = 464.4 \text{ W}$$

$$\text{F.L. output} = 25 \times 0.8 = 20 \text{ kW} = 20,000 \text{ W}$$

$$\text{Full-load } \eta = 20,000 \times 100 / (20,000 + 464.4) = \mathbf{97.7 \%}$$

**Example 32.65.** A 4-kVA, 200/400-V, 1-phase transformer has equivalent resistance and reactance referred to low-voltage side equal to 0.5  $\Omega$  and 1.5  $\Omega$  respectively. Find the terminal voltage on the high-voltage side when it supplies 3/4th full-load at power factor of 0.8, the supply voltage being 220 V. Hence, find the output of the transformer and its efficiency if the core losses are 100 W.

(Electrical Engineering ; Bombay Univ. 1985)

**Solution.** Obviously, primary is the low-voltage side and the secondary, the high voltage side.

Here,  $R_{01} = 0.5 \Omega$  and  $X_{01} = 1.5 \Omega$ . These can be transferred to the secondary side with the help of the transformation ratio.

$$K = 400/200 = 2 ; R_{02} = K^2 R_{01} = 2^2 \times 0.5 = 2 \Omega ; X_{02} = K^2 X_{01} = 4 \times 1.5 = 6 \Omega$$

$$\text{Secondary current when load is 3/4 the, full-load is} = (1,000 \times 4 \times 3/4) / 400 = 7.5 \text{ A}$$

Total drop as referred to transformer secondary is

$$= I_2 (R_{02} \cos \phi + X_{02} \sin \phi)^* = 7.5 (2 \times 0.8 + 6 \times 0.6) = 39 \text{ V}$$

$\therefore$  Terminal voltage on high-voltage side under given load condition is

$$= 400 - 39 = \mathbf{361 \text{ V}}$$

$$\text{Cu loss} = I_2^2 R_{02} = 7.5^2 \times 2 = 112.5 \text{ W}$$

$$\text{Iron loss} = 100 \text{ W}$$

$$\text{Total loss} = 212.5 \text{ W}$$

$$\text{output} = (4 \times 3/4) \times 0.8 = \mathbf{2.4 \text{ kW}}$$

$$\text{Input} = 2,400 + 212.5 = 2,612.5 \text{ W}$$

$$\eta = 2,400 \times 100 / 2,612.5 = \mathbf{91.87 \%}$$

**Example 32.66.** A 20-kVA, 440/220 V, I- $\phi$ , 50 Hz transformer has iron loss of 324 W. The Cu loss is found to be 100 W when delivering half full-load current. Determine (i) efficiency when

\* Assuming a lagging power factor

delivering full-load current at 0.8 lagging p.f. and (ii) the percent of full-load when the efficiency will be maximum. **(Electrotechnique-II, M.S. Univ., Baroda 1987)**

**Solution.** F.L. Cu loss =  $2^2 \times 100 = 400$  W ; Iron loss = 324 W

$$(i) \quad \text{F.L. efficiency at 0.8 p.f.} = \frac{20 \times 0.8}{(20 \times 0.8) + 0.724} \times 100 = \mathbf{95.67\%}$$

$$(ii) \quad \frac{\text{kVA for maximum}}{\text{F.L. kVA}} = \sqrt{\frac{\text{Iron loss}}{\text{F.L. Cu loss}}} = \sqrt{\frac{324}{400}} = 0.9$$

Hence, efficiency would be maximum at **90%** of F.L.

**Example 32.67.** Consider a 4-kVA, 200/400 V single-phase transformer supplying full-load current at 0.8 lagging power factor. The O.C./S.C. test results are as follows :

O.C. test : 200 V, 0.8 A, 70 W (I.V. side)

S.C. test : 20 V, 10 A, 60 (H.V. side)

Calculate efficiency, secondary voltage and current into primary at the above load.

Calculate the load at unity power factor corresponding to maximum efficiency.

**(Elect. Machines Nagpur Univ. 1993)**

**Solution.** Full-load,  $I_2 = 4000/400 = 10$  A

It means that S.C. test has been carried out with full secondary flowing. Hence, 60 W represents full-load Cu loss of the transformer.

Total F.L. losses =  $60 + 70 = 130$  W ; F.L. output =  $4 \times 0.8 = 3.2$  kW

F.L.  $\eta = 3.2/3.33 = 0.96$  or **96%**

**S.C. Test**

$$Z_{02} = 20/10 = 2 \Omega ; I_2^2 R_{02} = 60 \text{ or } R_{02} = 60/10^2 = 0.6 \Omega ; X_{02} = \sqrt{2^2 - 0.6^2} = 1.9 \Omega$$

Transformer voltage drop as referred to secondary

$$= I_2 (R_{02} \cos \phi + X_{02} \sin \phi) = 10 (0.6 \times 0.8 + 1.9 \times 0.6) = 16.2 \text{ V}$$

$$\therefore V_2 = 400 - 16.2 = 383.8 \text{ V}$$

Primary current =  $4000/200 = 20$  A

kVA corresponding to  $\eta_{max} = 4 \times \sqrt{70/60} = 4.32$  kVA

$\therefore$  Load at u.p.f. corresponding to  $\eta_{max} = 4.32 \times 1 = \mathbf{4.32}$  kW

**Example 32.68.** A 600 kVA, 1-phase transformer has an efficiency of 92 % both at full-load and half-load at unity power factor. Determine its efficiency at 60 % of full-load at 0.8 power factor lag.

**(Elect. Machines, A.M.I.E. Sec. B, 1992)**

**Solution.**

$$\eta = \frac{x \times kVA \times \cos \phi}{(x \times kVA) \times \cos \phi + W_i + x^2 W_{Cu}} \times 100$$

where  $x$  represents percentage of full-load

$W_i$  is iron loss and  $W_{Cu}$  is full-load Cu loss.

**At F.L. u.p.f.** Here  $x = 1$

$$\therefore 92 = \frac{1 \times 600 \times 1}{1 \times 600 \times 1 + W_i + 1^2 W_{Cu}} \times 100, W_i + W_{Cu} = 52.174 \text{ kW} \quad \dots(i)$$

At half F.L. UPF. Here  $x = 1/2$

$$92 = \frac{1/2 \times 600 \times 1}{(1/2) \times 600 \times 1 + W_i + (1/2)^2 W_{Cu}} \times 100 ;$$

$$\therefore W_i + 0.25 W_{Cu} = 26.087 \text{ kW} \quad \dots(ii)$$

From (i) and (ii), we get,  $W_i = 17.39 \text{ kW}$ ,  $W_{Cu} = 34.78 \text{ kW}$

**60 % F.L. 0.8 p.f. (lag)** Here,  $x = 0.6$

$$\eta = \frac{0.6 \times 600 \times 0.8 \times 100}{(0.6 \times 600 \times 0.8) + 17.39 + (0.6)^2 34.78} = \mathbf{85.9 \%}$$

**Example 32.69.** A 600-kVA, 1-ph transformer when working at u.p.f. has an efficiency of 92 % at full-load and also at half-load. Determine its efficiency when it operates at unity p.f. and 60 % of full-load. **(Electric Machines, Kerala Univ. 1987)**

**Solution.** The fact that efficiency is the same i.e. 92 % at both full-load and half-load will help us to find the iron and copper losses.

**At full-load**

Output = 600 kW ; Input =  $600/0.92 = 652.2 \text{ kW}$  ; Total loss =  $652.2 - 600 = 52.2 \text{ kW}$

Let  $x =$  Iron loss – It remains constant at all loads.  
 $y =$  F.L. Cu loss – It is  $\propto (\text{kVA})^2$ .  $\therefore x + y = 52.2 \quad \dots(i)$

**At half-load**

Output = 300 kW ; Input =  $300/0.92$   $\therefore$  Losses =  $(300/0.92 - 300) = 26.1 \text{ kW}$

Since Cu loss becomes one-fourth of its F.L. value, hence

$$x + y/4 = 26.1$$

Solving for  $x$  and  $y$ , we get  $x = \mathbf{17.4 \text{ kW}}$  ;  $y = 34.8 \text{ kW} \quad \dots(ii)$

**At 60 % full-load**

Cu loss =  $0.62 \times 34.8 = 12.53 \text{ kW}$  ; Total loss =  $17.4 + 12.53 = 29.93 \text{ kW}$

Output =  $600 \times 0.6 = 360 \text{ kW}$   $\therefore \eta = 360/389.93 = 0.965$  or **96.5 %**

**Example 32.70.** The maximum efficiency of a 100-kVA, single phase transformer is 98% and occurs at 80% of full load at 8 p.f. If the leakage impedance of the transformer is 5 %, find the voltage regulation at rated load of 0.8 power factor lagging.

**(Elect. Machines-I, Nagpur Univ. 1993)**

**Solution.** Since maximum efficiency occurs at 80 percent of full-load at 0.8 p.f.,

Output at  $\eta_{max} = (100 \times 0.8) \times 0.8 = 64 \text{ kW}$  ; Input =  $64/0.98 = 65.3 \text{ kW}$

$\therefore$  Total loss =  $65.3 - 64 = 1.3 \text{ kW}$ . This loss is divided equally between Cu and iron.

$\therefore$  Cu loss at 80 % of full-load =  $1.3/2 = 0.65 \text{ kW}$

Cu loss at full-load =  $0.65/0.8^2 = 1 \text{ kW}$

$$\% R = \frac{\text{Cu loss}}{V_2 I_2} \times 100 = 1 \times \frac{100}{100} = 1 \% = v_r ; v_x = 5 \%$$

$$\therefore \% \text{ age regn.} = (1 \times 0.8 + 5 \times 0.6) + \frac{1}{200} (5 \times 0.8 - 1 \times 0.6)^2 = \mathbf{0.166 \%}$$

**Example 32.71.** A 10 kVA, 5000/440-V, 25-Hz single phase transformer has copper, eddy current and hysteresis losses of 1.5, 0.5 and 0.6 per cent of output on full load. What will be the percentage losses if the transformer is used on a 10-kV, 50-Hz system keeping the full-load current constant ? Assume unity power factor operation. Compare the full load efficiencies for the two cases.

**(Elect. Machines, A.M.I.E., Sec. B, 1991)**

**Solution.** We know that  $E_1 = 4.44 f N_1 B_1 A$ . When both excitation voltage and frequency are doubled, flux remains unchanged.

F.L. output at upf =  $10 \text{ kVA} \times 1 = 10 \text{ kW}$

$$\begin{aligned} \text{F.L. Cu loss} &= 1.5 \times 10/100 = 0.15 \text{ kW} ; \text{ Eddy current loss} \\ &= 0.5 \times 10/100 = 0.05 \text{ kW} ; \text{ Hysteresis loss} = 0.6 \times 10/100 = 0.06 \text{ kW} \end{aligned}$$

Now, full-load current is kept constant but voltage is increased from 5000 V to 10,000 V. Hence, output will be doubled to 20 kW. Due to constant current, Cu loss would also remain constant.

$$\text{New Cu loss} = 0.15 \text{ kW}, \% \text{ Cu loss} = (0.15/20) \times 100 = 0.75 \%$$

Now, eddy current loss  $\propto f^2$  and hysteresis loss  $\propto f$ .

$$\text{New eddy current loss} = 0.05 (50/25)^2 = 0.2 \text{ kW}, \% \text{ eddy current loss} = (0.2/20) \times 100 = 1 \%$$

$$\text{Now, } W_h = 0.06 \times (50/25) = 0.12 \text{ kW}, \% W_h = (0.12/20) \times 100 = 0.6 \%$$

$$\eta_1 = \frac{10}{10 + 0.15 + 0.05 + 0.06} \times 100 = \mathbf{87.4 \%$$

$$\eta_2 = \frac{20}{20 + 0.15 + 0.2 + 0.12} \times 100 = \mathbf{97.7 \%$$

**Example 32.72.** A 300-kVA, single-phase transformer is designed to have a resistance of 1.5 % and maximum efficiency occurs at a load of 173.2 kVA. Find its efficiency when supplying full-load at 0.8 p.f. lagging at normal voltage and frequency. (Electrical Machines-I, Gujarat Univ. 1985)

$$\text{Solution. } \% R = \frac{\text{F.L. Cu loss}}{\text{Full-load } V_2 I_2} \times 100 ; 1.5 = \frac{\text{F.L. Cu loss}}{300 \times 1000} \times 100$$

$$\therefore \text{F.L. Cu loss} = 1.5 \times 300 \times 1000/100 = 4500 \text{ W}$$

$$\text{Also, } 173.2 = 300 \sqrt{\frac{\text{Iron Loss}}{4500}} ; \text{ Iron loss} = 1500 \text{ W}$$

$$\text{Total F.L. loss} = 4500 + 1500 = 6 \text{ kW}$$

$$\text{F.L. } \eta \text{ at } 0.8 \text{ p.f.} = \frac{300 \times 0.8}{(300 \times 0.8) + 6} \times 100 = \mathbf{97.6 \%$$

**Example 32.73.** A single phase transformer is rated at 100-kVA, 2300/230-V, 50 Hz. The maximum flux density in the core is 1.2 Wb/m<sup>2</sup> and the net cross-sectional area of the core is 0.04 m<sup>2</sup>. Determine

(a) The number of primary and secondary turns needed.

(b) If the mean length of the magnetic circuit is 2.5 m and the relative permeability is 1200, determine the magnetising current. Neglect the current drawn for the core loss.

(c) On short-circuit with full-load current flowing, the power input is 1200 W and an open-circuit with rated voltage, the power input was 400 W. Determine the efficiency of the transformer at 75 % of full-load with 0.8 p.f. lag.

(d) If the same transformer is connected to a supply of similar voltage but double the frequency (i.e., 100 Hz). What is the effect on its efficiency? (Elect. Engg., Bombay Univ. 1988)

**Solution.** (a) Applying e.m.f. equation of the transformer to the primary, we have

$$2300 = 4.44 \times 50 \times N_1 \times (1.2 \times 0.04) \quad \therefore N_1 = \mathbf{216}$$

$$K = 230/2300 = 1/10 \quad N_2 = KN_1 = 216/10 = 21.6 \text{ or } \mathbf{22}$$

$$(b) \quad AT = H \times l = \frac{B}{\mu_0 \mu_r} \times l = \frac{1.2 \times 2.5}{4\pi \times 10^{-7} \times 1200} = 1989 \quad \therefore I = \frac{1989}{216} = \mathbf{9.21 \text{ A}}$$

$$(c) \quad \text{F.L. Cu loss} = 1200 \text{ W} - \text{S.C. test} ; \text{ Iron loss} = 400 \text{ W} - \text{O.C. test}$$

$$\text{Cu loss at } 75 \% \text{ of F.L.} = (0.75)^2 \times 1200 = 675 \text{ W}$$

$$\text{Total loss} = 400 + 675 = 1075 \text{ kW}$$

$$\text{Output} = 100 \times (3/4) \times 0.8 = 60 \text{ kW} ; \eta = (60/61.075) \times 100 = \mathbf{98.26 \%$$

(d) When frequency is doubled, iron loss is increased because

(i) hysteresis loss is doubled –  $W_h \propto f$

(ii) eddy current loss is quadrupled –  $W_e \propto f^2$

Hence, efficiency will be decreased.

**Example 32.74.** A transformer has a resistance of 1.8 % and a reactance of 5.4 %. (a) At full load, what is the power-factor at which the regulation will be : (i) Zero, (ii) positive-maximum ? (b) If its maximum efficiency occurs at full-load (at unity p.f.), what will be the efficiency under these conditions ?

**Solution :** Approximate percentage regulation is given, in this case, by the relationship

$$1.8 \cos \phi \pm 5.4 \sin \phi.$$

(a) **Regulation :**

(i) If regulation is zero, negative sign must be applicable. This happens at leadings p.f.

$$\text{Corresponding p.f.} = \tan \phi = 1.8/5.4 = 0.333 \text{ leading}$$

$$\phi = 18.44^\circ \text{ leading}$$

(ii) For maximum positive regulation, lagging p.f. is a must. From phasor diagram, the result can be obtained.

$$\text{Corresponding } \tan \phi = 5.4/1.8 = 3, \phi = 71.56^\circ \text{ lagging}$$

$$\% \text{ Voltage regulation} = 1.8 \cos \phi + 5.4 \sin \phi = 5.7\%$$

(b) **Efficiency :** Maximum efficiency occurs at such a load when

$$\text{Iron losses} = \text{Copper losses}$$

This means Iron-losses are 1.8 %.

$$\text{Efficiency} = 100/(100 + 1.8 + 1.8) = 96.52\%$$

**Example 32.75.** A 10 kVA, 1 phase, 50 Hz, 500/250 V transformer gave following test results :

OC test (LV) side : 250 V, 3.0 A, 200 W

SC test (LV) side : 15 V, 30 A, 300 W.

Calculate efficiency and regulation at full load, 0.8 p.f. lagging.

(Nagpur University, Summer 2000)

**Solution.** For efficiency calculations, full load current should be calculated, on the L.V. side in this case,

$$\text{F.L. Current} = \frac{10,000}{250} = 40 \text{ amp}$$

Short-circuit test data have been given at 30 A current on the L.V. side.

$$i^2 r \text{ losses at 40 A L.V. side} = \left(\frac{40}{30}\right)^2 \times 300 \text{ Watts} = 533.3 \text{ Watts}$$

At rated voltage, iron losses (from O.C. test) = 200 Watts

F.L. Output at 0.8 P.F. = 10,000 × 0.8 = 8000 Watts

$$\text{Hence, } \eta = \frac{8000}{8000 + 4733.3} \times 100\% = 91.6\%$$

For regulation, series resistance and reactance parameters of the equivalent circuit have to be evaluated, from the S.C. test.

$$\text{Series Impedance, } Z = \frac{15}{30} = 0.5 \text{ ohm}$$

$$\text{Series resistance, } r = \frac{300}{30 \times 30} = 0.333 \text{ ohm}$$

$$\text{Series reactance, } x = \sqrt{0.5^2 - 0.333^2} = 0.373 \text{ ohm}$$

By Approximate formula,

p.u. regulation at full load, 0.8 p.f. lagging

$$= \frac{40}{250} [0.333 \times 0.8 - 0.373 \times 0.6] = 6.82 \times 10^{-3} \text{ p.u.}$$

When converted into volts, this is  $6.82 \times 10^{-3} \times 250 = 1.70 \text{ volt}$

**Example 32.76.** A 40 kVA, 1-ph, transformer has an iron loss of 400 W, and full copper loss of 800 W. Find the load at which maximum efficiency is achieved at unity power factor.

(Amravati University, Winter 1999)

**Solution.** If  $x$  = fraction of rated load at which the efficiency is maximum.

$$P_i = \text{Iron-loss} = 400 \text{ W}$$

$$P_c = \text{F.L. copper-loss} = 800 \text{ W}$$

Then

$$x^2 P_c = P_i$$

On substitution of numerical values of  $P_i$  and  $P_c$ , we get

$$x = 0.707$$

Hence, the efficiency is maximum, at unity p.f. and at 70.7 % of the rated Load. At this load, copper-loss = Iron-loss = 0.40 kW

$$\begin{aligned} \text{Corresponding output} &= 40 \times 0.707 \times 1 \\ &= 28.28 \text{ kW} \end{aligned}$$

$$\text{Corresponding efficiency} = \frac{28.28}{28.28 + 0.4 + 0.4} = 97.25 \%$$

**Extension to Question : (a)** At what load (s) at unity p.f. the efficiency will be 96.8 % ?

Fig. 32.58. Efficiency variation with load

**Solution.** Let  $x$  = Fractional load at which the concerned efficiency occurs, at unity p.f.

$$\frac{40x}{40x + 0.8x^2 + 0.40} = 0.968$$

This gives the following values of  $x$  :

$$x_1 = 1.25$$

$$x_2 = 0.40$$

Thus, at 40 % and at 125 % of the rated load, the efficiency will be **96.8 %** as marked on the graph, in Fig. 32.58.

**(b) How will maximum-efficiency condition be affected if the power factor is 0.90 lagging ?**

**Solution.**

The condition for efficiency-variation-statement is that the power factor remains constant. Thus, for 0.90 lagging p.f., another curve (Lower curve in Fig. 32.58) will be drawn for which the maximum efficiency will occur at the same value of  $x (= 0.707)$ , but

$$\begin{aligned} \text{Maximum efficiency} &= \frac{40 x \cos \phi}{40 \cos \phi + 0.80 x^2 + 0.40} \\ &= \frac{28.28 \times 0.90}{(28.28 \times 0.90) + 0.80} = \mathbf{97 \%} \end{aligned}$$

**Example 32.77.** A 10 kVA, 500/250 V, single-phase transformer gave the following test results:  
 S.C. Test (H.V. side) : 60 V, 20 A, 150 W  
 The maximum efficiency occurs at unity power factor and at 1.20 times full-load current. Determine full-load efficiency at 0.80 p.f. Also calculate the maximum efficiency.

**(Rajiv Gandhi Technical University, Bhopal, Summer 2001)**

**Solution.** Full-load current on H.V. side = 10,000/500 = 20 Amp

S.C. test has been conducted from H.V. side only. Hence, full-load copper-loss, at unity p.f. = 150 watts

**(a)** Maximum efficiency occurs at 1.2 times full-load current, at unity p.f. corresponding copper-loss =  $(1.2)^2 \times 150 = 216$  watts

At maximum efficiency, copper-loss = core-loss = 216 watts

Corresponding Power-output =  $1.2 \times 10,000 \times 1.0 = 12$  kW

Hence, maximum efficiency at unity P.f. =  $(12)/(12 + 0.216 + 0.2160) = 0.9653 = 96.53 \%$

**(b)** Full-load efficiency at 0.80 P.f.

Output Power at full-load, 0.80 P.f. =  $10,000 \times 0.8 = 8000$  W, constant core-loss = 216 W

Corresponding copper-loss = 150 W

Total losses = 366 W

Hence, efficiency =  $(8000/8366) \times 100 \% = 95.63 \%$ .

### 32.31. Variation of Efficiency with Power Factor

The efficiency of a transformer is given by

$$\begin{aligned} \eta &= \frac{\text{Output}}{\text{Input}} = \frac{\text{Input} - \text{Losses}}{\text{Input}} \\ &= 1 - \frac{\text{Losses}}{\text{Input}} = 1 - \frac{\text{Losses}}{(V_2 I_2 \cos \phi + \text{losses})} \end{aligned}$$

Let, losses/ $V_2 I_2 = x$

$$\begin{aligned} \therefore \eta &= 1 - \frac{\text{losses}/V_2 I_2}{\cos \phi + (\text{losses}/V_2 I_2)} \\ &= 1 - \frac{x}{(\cos \phi + x)} = 1 - \frac{x/\cos \phi}{1 + (x/\cos \phi)} \end{aligned}$$

The variations of efficiency with power factor at different loadings on a typical transformer are shown in Fig. 32.59.

Fig. 32.59

## Tutorial Problems 32.4

1. A 200-kVA transformer has an efficiency of 98 % at full-load. If the maximum efficiency occurs at three-quarters of full-load, calculate (a) iron loss at F.L. (b) Cu loss at F.L. (c) efficiency at half-load. Ignore magnetising current and assume a p.f. of 0.8 at all loads.  
 [(a) 1.777 kW (b) 2.09 kW (c) 97.92%]
2. A 600 kVA, 1-ph transformer has an efficiency of 92 % both at full-load and half-load at unity power factor. Determine its efficiency at 60 % of full load at 0.8 power factor lag.  
 [90.59%] (*Elect. Machines, A.M.I.E. Sec. B, 1992*)
3. Find the efficiency of a 150 kVA transformer at 25 % full load at 0.8 p.f. lag if the copper loss at full load is 1600 W and the iron loss is 1400 W. Ignore the effects of temperature rise and magnetising current.  
 [96.15%] (*Elect. Machines, A.M.I.E. Sec. B, 1991*)
4. The F.L. Cu loss and iron loss of a transformer are 920 W and 430 W respectively. (i) Calculate the loading of the transformer at which efficiency is maximum (ii) what would be the losses for giving maximum efficiency at 0.85 of full-load if total full-load losses are to remain unchanged ?  
 [(a) 68.4% of F.L. (ii)  $W_i = 565 \text{ W}$  ;  $W_{cu} = 785 \text{ W}$ ]
5. At full-load, the Cu and iron losses in a 100-kVA transformer are each equal to 2.5 kW. Find the efficiency at a load of 65 kVA, power factor 0.8.  
 [93.58%] (*City & Guilds London*)
6. A transformer, when tested on full-load, is found to have Cu loss 1.8% and reactance drop 3.8%. Calculate its full-load regulation (i) at unity p.f. (ii) 0.8 p.f. lagging (iii) 0.8 p.f. leading.  
 [(i) 1.80% (ii) 3.7 % (iii) -0.88%]
7. With the help of a vector diagram, explain the significance of the following quantities in the open-circuit and short-circuit tests of a transformer (a) power consumed (b) input voltage (c) input current. When a 100-kVA single-phase transformer was tested in this way, the following data were obtained : On open circuit, the power consumed was 1300 W and on short-circuit the power consumed was 1200 W. Calculate the efficiency of the transformer on (a) full-load (b) half-load when working at unity power factor.  
 [(a) 97.6% (b) 96.9%] (*London Univ.*)
8. An 11,000/230-V, 150-kVA, 50-Hz, 1-phase transformer has a core loss of 1.4 kW and full-load Cu loss of 1.6 kW. Determine (a) the kVA load for maximum efficiency and the minimum efficiency (b) the efficiency at half full-load at 0.8 power factor lagging.  
 [140.33 kVA, 97.6% ; 97%]
9. A single-phase transformer, working at unity power factor has an efficiency of 90 % at both half-load and a full-load of 500 kW. Determine the efficiency at 75 % of full-load. [90.5%] (*I.E.E. London*)
10. A 10-kVA, 500/250-V, single-phase transformer has its maximum efficiency of 94 % when delivering 90 % of its rated output at unity power factor. Estimate its efficiency when delivering its full-load output at p.f. of 0.8 lagging.  
 [92.6%] (*Elect. Machinery, Mysore Univ, 1979*)
11. A single-phase transformer has a voltage ratio on open-circuit of 3300/660-V. The primary and secondary resistances are  $0.8 \Omega$  and  $0.03 \Omega$  respectively, the corresponding leakage reactance being  $4 \Omega$  and  $0.12 \Omega$ . The load is equivalent to a coil of resistance  $4.8 \Omega$  and inductive reactance  $3.6 \Omega$ . Determine the terminal voltage of the transformer and the output in kW.  
 [636 V, 54 kW]
12. A 100-kVA, single-phase transformer has an iron loss of 600 W and a copper loss of 1.5 kW at full-load current. Calculate the efficiency at (a) 100 kVA output at 0.8 p.f. lagging (b) 50 kVA output at unity power factor.  
 [(a) 97.44% (b) 98.09%]
13. A 10-kVA, 440/3300-V, 1-phase transformer, when tested on open circuit, gave the following figures on the primary side : 440V ; 1.3 A ; 115 W. When tested on short-circuit with full-load current flowing, the power input was 140 W. Calculate the efficiency of the transformer at (a) full-load unity p.f. (b) one quarter full-load 0.8 p.f.  
 [(a) 97.51% (b) 94.18%] (*Elect. Engg-I, Sd. Patel Univ. June 1977*)
14. A 150-kVA single-phase transformer has a core loss of 1.5 kW and a full-load Cu loss of 2 kW. Calculate the efficiency of the transformer (a) at full-load, 0.8 p.f. lagging (b) at one-half full-load

unity p.f. Determine also the secondary current at which the efficiency is maximum if the secondary voltage is maintained at its rated value of 240 V. **[(a) 97.17% (b) 97.4% ; 541 A]**

15. A 200-kVA, 1-phase, 3300/400-V transformer gave the following results in the short-circuit test. With 200 V applied to the primary and the secondary short-circuited, the primary current was the full-load value and the input power 1650 W. Calculate the secondary p.d. and percentage regulation when the secondary load is passing 300 A at 0.707 p.f. lagging with normal primary voltage. **[380 V ; 480%]**
16. The primary and secondary windings of a 40-kVA, 6600/250-V, single-phase transformer have resistances of  $10\ \Omega$  and  $0.02\ \Omega$  respectively. The leakage reactance of the transformer referred to the primary is  $35\ \Omega$ . Calculate
- the primary voltage required to circulate full-load current when the secondary is short-circuited.
  - the full-load regulations at (i) unity (ii) 0.8 lagging p.f. Neglect the no-load current.
- [(a) 256 V (b) (i) 2.2% (ii) 3.7%] (Elect. Technology, Kerala Univ. 1979)**
17. Calculate :
- F.L. efficiency at unity p.f.
  - The secondary terminal voltage when supplying full-load secondary current at p.f. (i) 0.8 lag (ii) 0.8 lead for the 4-kVA, 200/400 V, 50 Hz, 1-phase transformer of which the following are the test figures :
- Open circuit with 200 V supplied to the primary winding-power 60 W. Short-circuit with 16 V applied to the h.v. winding-current 8 A, power 40 W. **[0.97 ; 383 V ; 406 V]**
18. A 100-kVA, 6600/250-V, 50-Hz transformer gave the following results :
- O.C. test : 900 W, normal voltage.  
S.C. test (data on h.v. side) : 12 A, 290 V, 860 W
- Calculate
- the efficiency and percentage regulation at full-load at 0.8 p.f. lagging.
  - the load at which maximum efficiency occurs and the value of this efficiency at p.f. of unity, 0.8 lag and 0.8 lead. **[(a) 97.3%, 4.32% (b) 81 kVA, 97.8%, 97.3% ; 97.3%]**
19. The primary resistance of a 440/110-V transformer is  $0.5\ \Omega$  and the secondary resistance is  $0.04\ \Omega$ . When 440 V is applied to the primary and secondary is left open-circuited, 200 W is drawn from the supply. Find the secondary current which will give maximum efficiency and calculate this efficiency for a load having unity power factor. **[53 A ; 93.58%] (Basic Electricity & Electronics. Bombay Univ. 1981)**
20. Two tests were performed on a 40-kVA transformer to predetermine its efficiency. The results were:
- Open circuit : 250 V at 500 W  
Short circuit : 40 V at F.L. current, 750 W both tests from primary side.
- Calculate the efficiency at rated kVA and 1/2 rated kVA at (i) unity p.f. (ii) 0.8 p.f. **[96.97% ; 96.68% ; 96.24% ; 95.87%]**
21. The following figures were obtained from tests on a 30-kVA, 3000/110-V transformer :
- O.C. test : 3000 V 0.5 A 350 W ; S.C. test ; 150 V 10 A 500 W
- Calculate the efficiency of the transformer at
- full-load, 0.8 p.f.
  - half-load, unity p.f.
- Also, calculate the kVA output at which the efficiency is maximum. **[96.56% ; 97% ; 25.1 kVA]**
22. The efficiency of a 400 kVA, 1-phase transformer is 98.77 % when delivering full load at 0.8 power factor, and 99.13 % at half load and unity power factor. Calculate (a) the iron loss, (b) the full load copper loss. **[(a) 1012 W (b) 2973 W] (Rajiv Gandhi Technical University, 2000)**

### 32.32. All-day Efficiency

The ordinary or commercial efficiency of a transformer is given by the ratio

$$\frac{\text{Output in watts}}{\text{Input in watts}}$$

But there are certain types of transformers whose performance cannot be judged by this efficiency. Transformers used for supplying lighting and general network *i.e.*, distribution transformers have their primaries energised all the twenty-four hours, although their secondaries supply little or no-load much of the time during the day except during the house lighting period. It means that whereas core loss occurs throughout the day, the Cu loss occurs only when the transformers are loaded. Hence, it is considered a good practice to design such transformers so that core losses are very low. The Cu losses are relatively less important, because they depend on the load. The performance of such is compared on the basis of *energy* consumed during a certain time period, usually a day of 24 hours.

$$\therefore \eta_{\text{all-day}} = \frac{\text{Output in kWh (For 24 hours)}}{\text{Input in kWh}}$$

This efficiency is always less than the commercial efficiency of a transformer.

To find this all-day efficiency or (as it is also called) energy efficiency, we have to know the load cycle on the transformer *i.e.*, how much and how long the transformer is loaded during 24 hours. Practical calculations are facilitated by making use of a **load factor**.

**Example 32.78.** Find the all-day efficiency of 500-kVA distribution transformer whose copper loss and iron loss at full load are 4.5 kW and 3.5 kW respectively. During a day of 24 hours, it is loaded as under :

No. of hours	Loading in kW	Power factor
6	400	0.8
10	300	0.75
4	100	0.8
4	0	–

(Elect. Machines, Nagpur Univ. 1993)

**Solution.** It should be noted that a load of 400 kW at 0.8 p.f. is equal to  $400/0.8 = 500$  kVA. Similarly, 300 kW at 0.75 p.f. means  $300/0.75 = 400$  kVA and 100 kW at 0.8 p.f. means  $100/0.8 = 125$  kVA *i.e.*, one-fourth of the full-load.

$$\text{Cu loss at F.L. of 500 kVA} = 4.5 \text{ kW}$$

$$\text{Cu loss at 400 kVA} = 4.5 \times (400/500)^2 = 2.88 \text{ kW}$$

$$\text{Cu loss at 125 kVA} = 4.5 \times (125/500)^2 = 0.281 \text{ kW}$$

$$\begin{aligned} \text{Total Cu loss in 24 hrs} &= (6 \times 4.5) + (10 \times 2.88) + (4 \times 0.281) + (4 \times 0) \\ &= 56.924 \text{ kWh} \end{aligned}$$

The iron loss takes place throughout the day irrespective of the load on the transformer because its primary is energized all the 24 hours.

The world first 5,000 KVA amorphous transformer commissioned in August 2001 in Japan

$$\begin{aligned} \therefore \text{Iron loss in 24 hours} &= 24 \times 3.5 = 84 \text{ kWh} \\ \text{Total transformer loss} &= 56.924 + 84 = 140.924 \text{ kWh} \\ \text{Transformer output in 24 hrs} &= (6 \times 400) + (10 \times 300) + (4 \times 100) = 5800 \text{ kWh} \\ \therefore \eta_{\text{all-day}} &= \frac{\text{output}}{\text{output} + \text{losses}} = \frac{5800}{5800 + 140.924} = 0.976 \text{ or } \mathbf{97.6\%} \end{aligned}$$

**Example 32.79.** A 100-kVA lighting transformer has a full-load loss of 3 kW, the losses being equally divided between iron and copper. During a day, the transformer operates on full-load for 3 hours, one half-load for 4 hours, the output being negligible for the remainder of the day. Calculate the all-day efficiency. (Elect. Engg. Punjab Univ. 1990)

**Solution.** It should be noted that lighting transformers are taken to have a load p.f. of unity.

$$\begin{aligned} \text{Iron loss for 24 hour} &= 1.5 \times 24 = 36 \text{ kWh ; F.L. Cu loss} = 1.5 \text{ kW} \\ \therefore \text{Cu loss for 3 hours on F.L.} &= 1.5 \times 3 = 4.5 \text{ kWh} \\ \text{Cu loss at half full-load} &= 1.5/4 \text{ kW} \\ \text{Cu loss for 4 hours at half the load} &= (1.5/4) \times 4 = 1.5 \text{ kWh} \\ \text{Total losses} &= 36 + 4.5 + 1.5 = 42 \text{ kWh} \\ \text{Total output} &= (100 \times 3) + (50 \times 4) = 500 \text{ kWh} \\ \therefore \eta_{\text{all-day}} &= 500 \times 100/542 = \mathbf{92.26\%} \\ \text{Incidentally, ordinary or commercial efficiency of the transformer is} & \\ &= 100/(100 + 3) = 0.971 \text{ or } \mathbf{97.1\%} \end{aligned}$$

**Example 32.80.** Two 100-kW transformers each has a maximum efficiency of 98 % but in one the maximum efficiency occurs at full-load while in the other, it occurs at half-load. Each transformer is on full-load for 4 hours, on half-load for 6 hours and on one-tenth load for 14 hours per day. Determine the all-day efficiency of each transformer. (Elect. Machines-I, Vikram Univ. 1988)

**Solution.** Let  $x$  be the iron loss and  $y$  the full-load Cu loss. If the ordinary efficiency is a maximum at  $1/m$  of full-load, then  $x = y/m^2$ .

$$\begin{aligned} \text{Now,} \quad \text{output} &= 100 \text{ kW ; Input} = 100/0.98 \\ \therefore \text{Total losses} &= 100/0.98 - 100 = 2.04 \text{ kW} \\ \therefore y + x/m^2 &= 2.04 \end{aligned}$$

**1st Transformer**

$$\begin{aligned} \text{Here } m = 1 ; \quad y + y &= 2.04 ; y = 1.02 \text{ kW and } x = 1.02 \text{ kW} \\ \text{Iron loss for 24 hours} &= 1.02 \times 24 = 24.48 \text{ kWh} \\ \text{Cu loss for 24 hours} &= 4 \times 1.02 + 6 \times (1.02/4) + 14 (1.02/10^2) = 5.73 \text{ kWh} \\ \text{Total loss} &= 24.48 + 5.73 = 30.21 \text{ kWh} \\ &= 4 \times 100 + 6 \times 50 + 14 \times 10 = 840 \text{ kWh} \\ \therefore \eta_{\text{all-day}} &= 840/870.21 = 0.965 \text{ or } \mathbf{96.5\%} \end{aligned}$$

**2nd Transformer**

$$\begin{aligned} \text{Here} \quad 1/m &= 1/2 \text{ or } m = 2 \therefore y + y/4 = 2.04 \\ \text{or} \quad y &= 1.63 \text{ kW ; } x = 0.14 \text{ kW} \\ \text{Output} &= 840 \text{ kWh} \quad \dots\text{as above} \\ \text{Iron loss for 24 hours} &= 0.14 \times 24 = 3.36 \text{ kWh} \\ \text{Cu loss for 24 hours} &= 4 \times 1.63 + 6 (1.63/4) + 14 (1.63/10^2) = 9.19 \text{ kWh} \\ \text{Total loss} &= 3.36 + 9.19 = 12.55 \text{ kWh} \\ \therefore \eta_{\text{all-day}} &= 840/852.55 = 0.974 \text{ or } \mathbf{97.4\%} \end{aligned}$$

**Example 32.81.** A 5-kVA distribution transformer has a full-load efficiency at unity p.f. of 95%, the copper and iron losses then being equal. Calculate its all-day efficiency if it is loaded throughout the 24 hours as follows :

No load for 10 hours      Quarter load for 7 hours  
Half load for 5 hours      Full load for 2 hours

Assume load p.f. of unity.

(Power Apparatus-I, Delhi Univ. 1987)

**Solution.** Let us first find out the losses from the given commercial efficiency of the transformer.

Output =  $5 \times 1 = 5$  kW ; Input =  $5/0.95 = 5.264$  kW

Losses =  $(5.264 - 5.000) = 0.264$  kW = 264W

Since efficiency is maximum, the losses are divided equally between Cu and iron.

$\therefore$  Cu loss at F.L. of 5 kVA =  $264/2 = 132$  W ; Iron loss = 132 W

Cu loss at one-fourth F.L. =  $(1/4)^2 \times 132 = 8.2$  W

Cu loss at one-half F.L. =  $(1/2)^2 \times 132 = 33$  W

Quarter load Cu loss for 7 hours =  $7 \times 8.2 = 57.4$  Wh

Half-load Cu loss for 5 hours =  $5 \times 33 = 165$  Wh

F.L. Cu loss for 2 hours =  $2 \times 132 = 264$  Wh

Total Cu loss during one day =  $57.4 + 165 + 264 = 486.4$  Wh = 0.486 kWh

Iron loss in 24 hours =  $24 \times 132 = 3168$  Wh = 3.168 kWh

Total losses in 24 hours =  $3.168 + 0.486 = 3.654$  kWh

Since load p.f. is to be assumed as unity.

F.L. output =  $5 \times 1 = 5$  kW ; Half F.L. output =  $(5/2) \times 1 = 2.5$  kW

Quarter load output =  $(5/4) \times 1 = 1.25$  kW

Transformer output in a day of 24 hours =  $(7 \times 1.25) + (5 \times 2.5) + (2 \times 5) = 31.25$  kWh

$$\eta_{\text{all-day}} = \frac{31.25}{(31.25 + 3.654)} \times 100 = 89.53 \%$$

**Example 32.82.** Find “all day” efficiency of a transformer having maximum efficiency of 98% at 15 kVA at unity power factor and loaded as follows :

12 hours – 2 kW at 0.5 p.f. lag

6 hours – 12 kW at 0.8 p.f. lag

6 hours – at no load.

(Elect. Machines-I, Nagpur Univ. 1993)

**Solution.**

Output =  $15 \times 1 = 15$  kW, input =  $15/0.98$

Losses =  $(15/0.98 - 15) = 0.306$  kW = 306 W

Since efficiency is maximum, the losses are divided equally between Cu and iron.

$\therefore$  Cu loss at 15 kVA =  $306/2 = 153$  W, Iron loss = 153 W

2 kW at 0.5 p.f. =  $2/0.5 = 4$  kVA, 12 kW at 0.8 p.f. =  $12/0.8 = 15$  kVA

Cu loss at 4 kVA =  $153 (4/15)^2 = 10.9$  W ; Cu loss at 15 kVA = 153 W.

Cu loss in 12 hrs =  $12 \times 10.9 = 131$  Wh ; Cu loss in 6 hr =  $6 \times 153 = 918$  Wh.

Total Cu loss for 24 hr =  $131 + 918 = 1050$  Wh = 1.05 kWh

Iron loss for 24 hrs =  $24 \times 153 = 3,672$  Wh = 3.672 kWh

Output in 24 hrs =  $(2 \times 12) + (6 \times 12) = 96$  kWh

Input in 24 hrs =  $96 + 1.05 + 3.672 = 100.72$  kWh

$\therefore$   $\eta_{\text{all-day}} = 96 \times 100/100.72 = 95.3 \%$

**Example 32.83.** A 150-kVA transformer is loaded as follows :

Load increases from zero to 100 kVA in 3 hours from 7 a.m. to 10.00 a.m., stays at 100 kVA from 10 a.m. to 6 p.m. and then the transformer is disconnected till next day. Assuming the load to be resistive and core-loss equal to full-load copper loss of 1 kW, determine the all-day efficiency and the ordinary efficiency of the transformer. **(Electrical Machines-II, Indore Univ. 1990)**

**Solution.** Since load is resistive, its p.f. is unity.

Average load from 7 a.m. to 10 a.m. =  $(0 + 100)/2 = 50$  kVA *i.e.*, one-third F.L.

Load from 10 a.m. to 6 p.m. = 100 kVA *i.e.*, 2/3 of F.L.

#### Ordinary Efficiency

In this case, load variations are not relevant.

Output =  $150 \times 1 = 150$  kW ; Iron loss = Cu loss = 1 kW ; Total loss = 2 kW.

$\therefore$  Ordinary  $\eta = 150/(150 + 2) = 0.9868$  or **98.68 %**

#### All-day Efficiency

Cu loss from 7-10 a.m. =  $3 \times (1/3)^2 \times 1 = 0.333$  kWh

Cu loss from 10 a.m. to 6 p.m. =  $8 \times (2/3)^2 \times 1 = 3.555$  kWh

Total Cu loss for 24 hrs =  $0.333 + 3.555 = 3.888$  kWh

Total iron loss for 24 hrs =  $24 \times 1 = 24$  kWh

Losses for a day of 24 hrs = 27.888 kWh

Output for 24 hrs =  $3 \times (50 \times 1) + 8 (100 \times 1) = 950$  kWh

$\therefore \eta_{\text{all-day}} = \frac{950 \times 100}{(950 + 27.888)} = \mathbf{97.15 \%}$

**Example 32.84.** Find the all-day efficiency of a 50 kVA distribution transformer having full load efficiency of 94 % and full-load copper losses are equal to the constant iron losses. The loading of the transformer is as follows, the power factor being 1.0.

(i) No load for 10 hours

(ii) Half load for 5 hours

(iii) 25 % load for 6 hours

(iv) Full load for 3 hours.

**(Sambalpur University, 1998)**

**Solution.** At full load unity p.f.

$$\text{efficiency} = 94 \% = \frac{50,000}{50,000 + 2P_i}$$

$$2P_i = \left[ \frac{50,000}{0.94} - 50,000 \right], \quad \text{or} \quad P_i = \frac{1}{2} \times 50,000 \left[ \frac{1 - 0.94}{0.94} \right],$$

$$P_i = 25,000 \times \frac{0.06}{0.94} = 1596 \text{ Watts}$$

Hence, full load Cu-losses = 1596 Watts

(a) Energy required in overcoming Cu-losses, during 24 hours

(i) No load for 10 hours : zero

(ii) At half load, Cu-losses =  $(0.5)^2 \times 1596$  Watts = 399

$$\text{Energy in 5 hours} = \frac{399 \times 5}{1000} \text{ kWh} = 1.995 \text{ kWh}$$

(iii) At 25 % load, Cu-loss =  $(0.25)^2 \times 1596 = 99.75$  Watts

$$\text{Energy in 6 hours} = \frac{6 \times 99.75}{1000} = 0.5985 \text{ kWh}$$

(iv) Energy lost during 3 hours of full load =  $\frac{1596 \times 3}{1000} = 4.788$  kWh

(b) Energy lost in constant core-losses for 24 hours =  $\frac{1596}{1000} \times 24 = 38.304$  kWh

(c) Energy required by the load =  $25 \times 5 + 12.5 \times 6 + 50 \times 3 = 125 + 75 + 150 = 350 \text{ kWh}$

$$\text{All-day efficiency} = \frac{350}{350 + 38.304 + 7.3815} \times 100 = 88.454 \%$$

**Example 32.85.** A 10 kVA, 1-ph transformer has a core-loss of 40 W and full load ohmic loss of 100 W. The daily variation of load on the transformer is as follows :

6 a.m. to 1 p.m. 3 kW at 0.60 p.f.  
 1 p.m. to 5 p.m. - 8kW at 0.8 p.f.  
 5 p.m. to 1 a.m. full load at u.p.f.  
 1 a.m. to 6 a.m. no load

Determine all day efficiency of the transformer

(Amravati University, 1999)

**Solution.** Fractional loading (=  $x$ ) and the output kWh corresponding to load variations can be worked out in tabular form, as below :

S.N.	Number of hours	$x = \frac{\text{load kVA}}{\text{Xmer Rating}}$	$x^2 P_c$ in kW	Output in kWh	Copper Loss in kWh
1	7	$\frac{3/0.6}{10} = 0.5$	$0.50^2 \times 0.10 = 0.025$	$3 \times 7 = 21$	$0.025 \times 7 = 0.175$
2	4	$\frac{8/0.8}{10} = 1.0$	0.10	$8 \times 4 = 32$	$0.1 \times 4 = 0.40$
3	8	$\frac{10/1}{10} = 1.0$	0.10	$10 \times 8 = 80$	$0.1 \times 8 = 0.8$
4	5	Zero	Zero	Zero	Zero
Output in kWh				$21 + 32 + 80 = 133$	
Ohmic Loss, in kWh					$0.175 + 0.40 + 0.80 = 1.375$
Core loss during 24 Hrs = $\frac{400}{1000} \times 24 = 0.96 \text{ kWh}$					

Hence, Energy efficiency (= All day Efficiency) =  $\frac{133}{133 + 1.375 + 0.96} \times 100 = 98.3 \%$

**Example 32.86.** A transformer has its maximum efficiency of 0.98 at 15 kVA at unity p.f. During a day, it is loaded as follows :

12 hours : 2 kW at 0.8 p.f.  
 6 hours : 12 kW at 0.8 p.f.  
 6 hours : 18 kW at 0.9 p.f.

Find the all day efficiency.

(Manomaniam Sundaranar Univ. April 1998)

**Solution.** Let 15 kVA be treated as full load.

Output at maximum efficiency =  $15000 \times 1$  watts

Input =  $15000/0.98$  watts

Losses = Input - Output =  $15000 (1/0.98 - 1) = 15000 \times 2/98 = 306$  Watts

At maximum efficiency, since the variable copper-loss and constant core-loss are equal.

Full load copper-loss = Constant core-loss =  $306/2 = 153$  Watts

Let the term  $x$  represents the ratio of required Load/Full load.

Output =  $15 \times \cos \phi$

Following tabular entries simplify the calculations for all-day efficiency.

S.N.	$x$	Hrs	$x^2 P_c$ in kW	Energy in Copper-loss in kWh	Output during the period in kWh
1	$\frac{2/0.5}{15} = \frac{4}{15}$	12	0.01088	0.131	24
2	$\frac{12/0.8}{15} = 1.0$	6	0.153	0.918	72
3	$\frac{18/0.9}{15} = 4/3$	6	0.272	1.632	108

Total output during the day = 204 kWh

Total copper-loss during the day = 2.681 kWh

Total core-loss during the day =  $0.153 \times 24 = 3.672$

All day efficiency =  $(204/210.353) \times 100 = 96.98\%$

### Tutorial Problems 32.5

1. A 100-kVA distribution transformer has a maximum efficiency of 98 % at 50 % full-load and unity power factor. Determine its iron losses and full-load copper losses.

The transformer undergoes a daily load cycle as follows :

Load	Power factor	Load duration
100 kVA	1.0	8 hrs
50 kVA	0.8	6 hrs
No load		10 hrs

Determine its all-day efficiency.

(Electrical Engineering, MS Univ. Baroda 1979)

2. What is meant by energy efficiency of a transformer ?

A 20-kVA transformer has a maximum efficiency of 98 percent when delivering three-fourth full-load at u.p.f. If during the day, the transformer is loaded as follows :

12 hours	No load
6 hours	12 kWh, 0.8 p.f.
6 hours	20 kW, u.p.f.

Calculate the energy efficiency of the transformer.

(Electrical Technology-III, Gwalior Univ., 1980)

### 32.33. Auto-transformer

It is a transformer with one winding only, part of this being common to both primary and secondary. Obviously, in this transformer the primary and secondary are not electrically *isolated* from each other as is the case with a 2-winding transformer. But its theory and operation are similar to those of a two-winding transformer. Because of one winding, it uses less copper and hence is cheaper. It is used where transformation ratio differs little from unity. Fig. 32.60 shows both step down and step-up auto-transformers.

As shown in Fig. 32.60 (a),  $AB$ , is primary winding having  $N_1$  turns and  $BC$  is secondary winding having  $N_2$  turns. Neglecting iron losses and no-load current.

$$\frac{V_2}{V_1} = \frac{N_2}{N_1} = \frac{I_1}{I_2} = K$$

The current in section *CB* is vector difference\* of  $I_2$  and  $I_1$ . But as the two currents are practically in phase opposition, the resultant current is  $(I_2 - I_1)$  where  $I_2$  is greater than  $I_1$ .

As compared to an ordinary 2-winding transformer of same output, an auto-transformer has higher efficiency but smaller size. Moreover, its voltage regulation is also superior.

**Saving of Cu**

Volume and hence weight of Cu, is proportional to the length and area of the cross-section of the conductors.

Now, length of conductors is proportional to the number of turns and cross-section depends on current. Hence, weight is proportional to the product of the current and number of turns.

With reference to Fig. 32.60,

Wt. of Cu in section *AC* is  $\propto (N_1 - N_2) I_1$ ; Wt. of Cu in section *BC* is  $\propto N_2 (I_2 - I_1)$ .

$\therefore$  Total Wt. of Cu in auto-transformer  $\propto (N_1 - N_2) I_1 + N_2 (I_2 - I_1)$

If a two-winding transformer were to perform the same duty, then

Wt. of Cu on its primary  $\propto N_1 I_1$ ; Wt. of Cu on secondary  $\propto N_2 I_2$

Total Wt. of Cu  $\propto N_1 I_1 + N_2 I_2$

$$\begin{aligned} \therefore \frac{\text{Wt. of Cu in auto-transformer}}{\text{Wt. of Cu in ordinary transformer}} &= \frac{(N_1 - N_2) I_1 + N_2 (I_2 - I_1)}{N_1 I_1 + N_2 I_2} \\ &= 1 - \frac{2 \frac{N_2}{N_1}}{1 + \frac{N_2}{N_1} \times \frac{I_2}{I_1}} = 1 - \frac{2K}{2} = 1 - K \left( \because \frac{N_1}{N_2} = K ; \frac{I_2}{I_1} = \frac{1}{K} \right) \end{aligned}$$

Wt. of Cu in auto-transformer ( $W_a$ ) =  $(1 - K) \times$  (Wt. of Cu in ordinary transformer  $W_0$ )

$$\begin{aligned} \therefore \text{Saving} &= W_0 - W_a \\ &= W_0 - (1 - K) W_0 = K W_0 \end{aligned}$$

$\therefore$  Saving =  $K \times$  (Wt. of Cu in ordinary transformer)

Hence, saving will increase as  $K$  approaches unity.

It can be proved that power transformed **inductively** is input  $(1 - K)$ .

The rest of the power =  $(K \times$  input) is **conducted** directly from the source to the load *i.e.*, it is transferred **conductively** to the load.

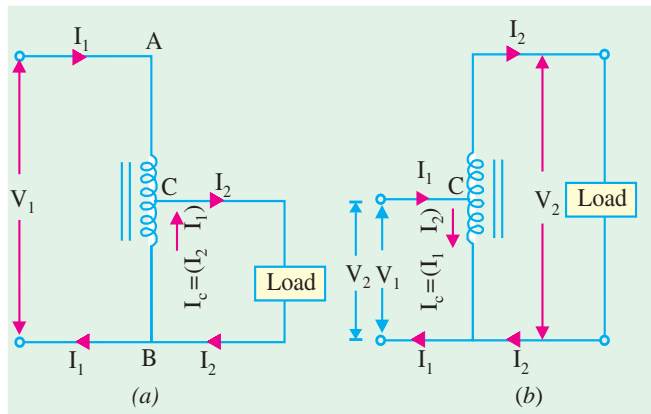

Fig. 32.60

Step up auto-transformer

\* In fact, current flowing in the common winding of the auto-transformer is always equal to the difference between the primary and secondary currents of an ordinary transformer.

**Uses**

As said earlier, auto-transformers are used when  $K$  is nearly equal to unity and where there is no objection to electrical connection between primary and secondary. Hence, such transformers are used :

1. to give small boost to a distribution cable to correct the voltage drop.
2. as auto-starter transformers to give upto 50 to 60 % of full voltage to an induction motor during starting.
3. as furnace transformers for getting a convenient supply to suit the furnace winding from a 230-V supply
4. as interconnecting transformers in 132 kV/330 kV system.
5. in control equipment for 1-phase and 3-phase electrical locomotives.

**Example 32.87.** An auto-transformer supplies a load of 3 kW at 115 volts at a unity power factor. If the applied primary voltage is 230 volts, calculate the power transferred to the load

(a) inductively and (b) conductively. (Basic Elect. Machines, Nagpur Univ, 1991)

**Solution.** As seen from Art 32.33

Power transferred inductively = Input  $(1 - K)$

Power transferred conductively = Input  $\times K$

Now,  $K = 115/230 = 1/2$ , input  $\cong$  output = 3 kW

$\therefore$  Inductively transferred power =  $3(1 - 1/2) = 1.5 \text{ kW}$

Conductively transferred power =  $(1/2) \times 3 = 1.5 \text{ kW}$

**Example 32.88.** The primary and secondary voltages of an auto-transformer are 500 V and 400 V respectively. Show with the aid of diagram, the current distribution in the winding when the secondary current is 100 A and calculate the economy of Cu in this particular case.

**Solution.** The circuit is shown in Fig. 30.61.

$$K = V_2/V_1 = 400/500 = 0.8$$

$$\therefore I_1 = KI_2 = 0.8 \times 100 = 80 \text{ A}$$

The current distribution is shown in Fig. 32.61.

Saving =  $K W_0 = 0.8 W_0$  - Art 32.33

$$\therefore \text{Percentage saving} = 0.8 \times 100 = 80$$

Fig. 32.61

**Example 32.89.** Determine the core area, the number of turns and the position of the tapping point for a 500-kVA, 50-Hz, single-phase, 6,600/5,000-V auto-transformer, assuming the following approximate values : e.m.f. per turn 8 V. Maximum flux density 1.3 Wb/m<sup>2</sup>.

**Solution.**

$$E = 4.44f\Phi_m N \text{ volt}$$

$$\Phi_m = \frac{E/N}{4.44f} = \frac{8}{4.44 \times 50} = 0.03604 \text{ Wb}$$

$$\text{Core area} = 0.03604/1.3 = 0.0277 \text{ m}^2 = 277 \text{ cm}^2$$

$$\text{Turns of h.v. side} = 6600/8 = 825 ; \text{Turns of L.V. side} = 5000/8 = 625$$

Hence, tapping should be 200 turns from high voltage end or 625 turns from the common end.

**32.34. Conversion of 2-Winding Transformer into Auto-transformer**

Any two-winding transformer can be converted into an auto-transformer either step-down or step-up. Fig. 32.62 (a) shows such a transformer with its polarity markings. Suppose it is a 20-kVA,

2400/240 V transformer. If we employ *additive* polarity between the high-voltage and low-voltage sides, we get a step-up auto-transformer. If, however, we use the *subtractive* polarity, we get a step-down auto-transformer.

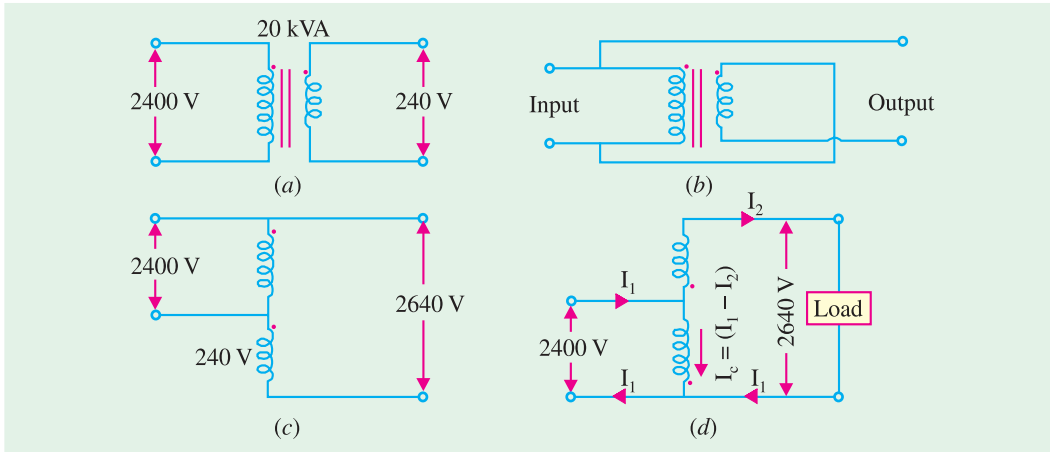

Fig. 32.62

**(a) Additive Polarity**

Connections for such a polarity are shown in Fig. 32.62 (b). The circuit is re-drawn in Fig. 32.62 (c) showing common terminal of the transformer at the top whereas Fig. 32.62 (d) shows the same circuit with common terminal at the bottom. Because of additive polarity,  $V_2 = 2400 + 240 = 2640$  V and  $V_1$  is 2400 V. There is a marked increase in the kVA of the auto-transformer (Ex. 32.90). As shown in Fig. 32.62 (d), common current flows *towards* the common terminal. The transformer acts as a step-up transformer.

**(b) Subtractive Polarity**

Such a connection is shown in Fig. 32.63 (a). The circuit has been re-drawn with common polarity at top in Fig. 32.63 (b) and at bottom in Fig. 32.63 (c). In this case, the transformer acts as a step-down auto-transformer.

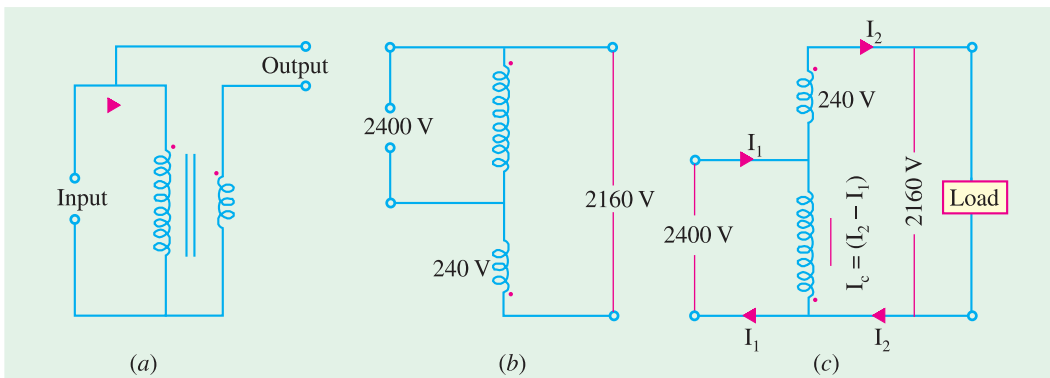

Fig. 32.63

The common current flows *away* from the common terminal. As will be shown in Example 32.91, in this case also, there is a very large increase in kVA rating of the auto-transformer though not as marked as in the previous case. Here,  $V_2 = 2400 - 240 = 2160$  V.

**Example 32.90.** For the 20-kVA, 2400/240-V two-winding step-down transformer shown in Fig. 32.63 (a) connected as an auto-transformer with additive polarity as shown in Fig. 30.61 (d), compute

- (i) original current capacity of HV-windings.
- (ii) original current capacity of LV-windings.
- (iii) kVA rating of auto-transformer using current capacity of current LV winding as calculated in (ii) above.
- (iv) per cent increase in kVA capacity of auto-transformer as compared to original two-winding transformer.
- (v) values of  $I_1$  and  $I_c$  in Fig. 30.61 (d) from value of  $I_2$  used in (iii) above.
- (vi) per cent overload of 2400-V winding when used as an auto-transformer.
- (vii) comment on the results obtained.

**Solution.** (i)  $I_1 = 20 \times 10^3 / 2400 = 8.33 \text{ A}$  (ii)  $I_2 = I_1 / K = 8.33 \times 10 = 83.3 \text{ A}$   
 (iii) kVA rating of auto-transformer  $V_2 I_2 = 2640 \times 83.3 \times 10^{-3} = 220 \text{ kVA}$   
 (iv) Per cent increase in kVA rating =  $\frac{220}{20} \times 100 = 1100\%$   
 (v)  $I_1 = 220 \times 10^3 / 2400 = 91.7 \text{ A}$ ,  $I_c = I_1 - I_2 = 91.7 - 83.3 = 8.4 \text{ A}$   
 (vi) Per cent overload of 2400 V winding =  $8.4 \times 100 / 8.33 = 100.8\%$   
 (vii) As an auto-transformer, the kVA has increased tremendously to 1100% of its original value with LV coil at its rated current capacity and HV coil at negligible overload i.e.  $1.008 \times$  rated load.

**Example 32.91.** Repeat Example 30.64 for subtractive polarity as shown in Fig. 32.62 (c).

**Solution.** (i)  $I_1 = 8.33 \text{ A}$  (ii)  $I_2 = 83.3 \text{ A}$   
 (iii) New kVA rating of auto-transformer is  $2160 \times 83.3 \times 10^{-3} = 180 \text{ kVA}$   
 (iv) Per cent increase in kVA rating =  $\frac{180}{20} \times 100 = 900\%$   
 (v)  $I_1 = 180 \times 10^3 / 2400 = 75 \text{ A}$ ,  $I_c = I_2 - I_1 = 83.3 - 75 = 8.3 \text{ A}$   
 (vi) Per cent overload of 2400V winding =  $8.3 \times 100 / 8.33 = 100\%$   
 (vii) In this case, kVA has increased to 900% of its original value as a two-winding transformer with both low-voltage and high-voltage windings carrying their rated currents.

The above phenomenal increase in kVA capacity is due to the fact that in an auto-transformer energy transfer from primary to secondary is by both conduction as well as induction whereas in a 2-winding transformer it is by induction only. This extra conductive link is mainly responsible for the increase in kVA capacity.

**Example 32.92.** A 5-kVA, 110/110-V, single-phase, 50-Hz transformer has full-load efficiency of 95% and an iron loss of 50 W. The transformer is now connected as an auto-transformer to a 220-V supply. If it delivers a 5-kW load at unity power factor to a 110-V circuit, calculate the efficiency of the operation and the current drawn by the high-voltage side.

(Electric Machinery-II, Bangalore Univ. 1991)

**Solution.** Fig. 32.64 (a) shows the normal connection for a 2-winding transformer. In Fig. 32.64 (b) the same unit has been connected as an auto transformer. Since the two windings are connected in series, voltage across each is 110 V.

The iron loss would

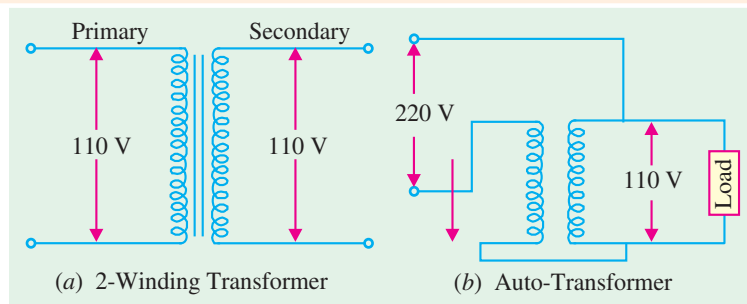

Fig. 32.64

remain the same in both connections. Since the auto-transformer windings will each carry but half the current as compared to the conventional two-winding transformer, the copper loss will be one-fourth of the previous value.

**Two-winding Transformer**

$$\eta = 0.95 \quad \therefore 0.95 = \frac{\text{output}}{\text{output} + \text{losses}} = \frac{5,000}{5,000 + 50 + \text{Cu loss}}$$

$$\therefore \text{Cu loss} = 212 \text{ W}$$

**Auto-transformer**

$$\text{Cu loss} = 212/4 = 53 \text{ W}; \text{ Iron loss} = 50 \text{ W} \quad \therefore \eta = \frac{5,000}{5,000 + 53 + 50} = 0.9797 \text{ or } \mathbf{97.97\%}$$

$$\text{Current of the h.v. side} = 5103/220 = \mathbf{23.2 \text{ A}}$$

**Example 32.93.** A transformer has a primary voltage rating of 11500 volts and secondary voltage rating of 2300 volts. Two windings are connected in series and the primary is connected to a supply of 11500 volts, to act as a step-up auto transformer. Determine the voltage output of the transformer.

*Question extended :* If the two winding transformer is rated at 115 kVA, what will be the kVA rating of the auto-transformer ? **(Madras University, 1997)**

**Solution.** As in Fig. 32.65 (a), 115 kVA, 11500/2300 V, transformer has the current ratings of 10 A and 50 A.

Referring to Fig. 32.65 (b), the step-up connections have been shown. Winding currents have to be at the same rated values. As in Fig. 32.65 (b), the voltage obtainable at  $B_1 - B_2$  is 13800 V, and from  $b_1$  a load-current of 50 A can be supplied.

$$\text{kVA rating} = 13800 \times 50 \times 10^{-3} = 690$$

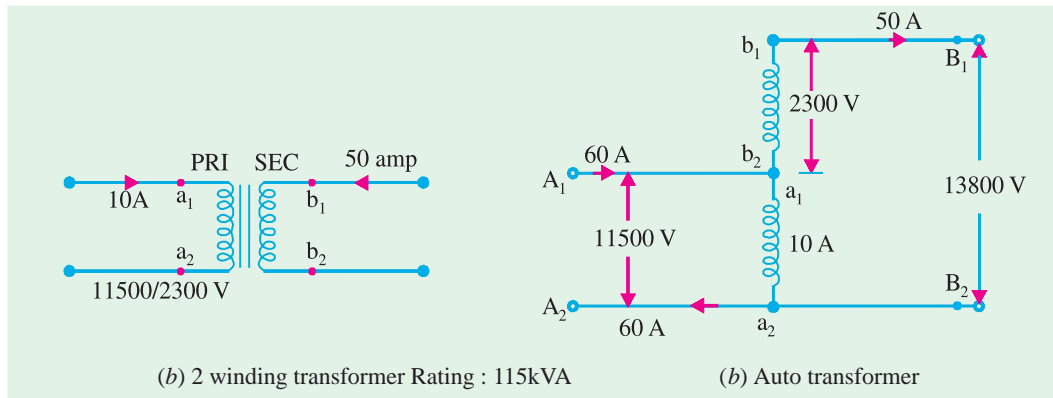

Fig. 32.65

**Example 32.94.** An 11500/2300 V transformer is rated at 100 kVA as a 2 winding transformer. If the two windings are connected in series to form an auto-transformer, what will be the possible voltage ratios ? **(Manonmaniam Sundaranar Univ. April 1998)**

**Solution.** Fig. 32.66 (a) shows this 2-winding transformer with rated winding currents marked.

Rated current of 11.5 kV winding =  $100 \times 100/11500 = 8.7$  Amp

Rated current of 2300 V winding = 43.5 Amp

Fig. 32.66 (b) and Fig. 32.66 (c) show autotransformer **Fig. 32.66 (a).** 2 winding transformer

connections. On H.V. side, they have a rating of 13.8 kV. On L.V. side, with connection as in Fig. 32.66 (b), the rating is 2300 V. On L.V. side of Fig. 32.66 (c), the output is at 11.5 kV.

Thus, possible voltage ratios are : 13800/2300 V and 13800/11500 V.

With both the connections, step-up or step-down versions are possible.

**Extension of Question :** Calculate kVA ratings in the two cases.

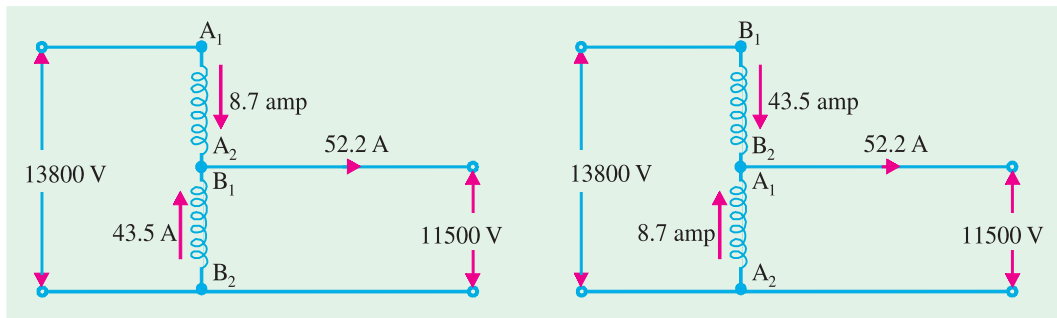

Fig. 32.66

Windings will carry the rated currents, while working out kVA outputs.

In Fig. 32.66 (b), Input current (into terminal  $A_1$  of windings  $A_1-A_2$ ) can be 8.7 Amp with H.V.-side-voltage ratings as 13.8 kV. Transformation ratio =  $13800/2300 = 6$

$$\text{Hence, kVA rating} = 13.8 \times 8.7 = 120$$

$$\text{Output current} = 120 \times 1000/2300 = 52.2 \text{ Amp}$$

$$\text{Current in the winding } B_1-B_2$$

$$= \text{Difference of Output current and Input current}$$

$$= 52.2 - 8.7 = 43.5 \text{ A, which is the rated current of the winding } B_1-B_2.$$

In Fig. 32.66 (c). Similarly, transformation ratio =  $13800/11500 = 1.2$

$$\text{kVA rating} = 13800 \times 43.5 \times 10^{-3} = 600$$

$$\text{Output current} = 600 \times 1000/11500 = 52.2 \text{ Amp}$$

Current carried by common winding =  $52.2 - 43.5 = 8.7 \text{ A}$ , which is rated current for the winding  $A_1-A_2$ . Thus, with the same two windings give, a transformation ratio closer to unity gives higher kVA rating as an auto transformer.

Thus, a 100 kVA two winding transformer is reconnected as an autotransformer of 120 kVA with transformation ratio as 6, and becomes a 600 kVA autotransformer with transformation ratio as 1.2.

**Example 32.95.** A two-winding transformer is rated at 2400/240 V, 50-kVA. It is re-connected as a step-up auto-transformer, with 2400 V input. Calculate the rating of the auto-transformer and the inductively and conductively transferred powers while delivering the rated output at unity power-factor.

(Nagpur University, Winter 1999)

**Solution.** With 50 kVA as the rating, the rated currents on the two sides are 20.8 A (2400-V side) and 208 A (240-V side). With the required re-connection, the 2400-V winding will work as a common winding. As shown in Fig. 32.67, the winding common to input and output can carry 20.8 A, the output current can be 208 A with a voltage of 2640 V, which means that the output of this auto

Fig. 32.67

transformer is  $(2640 \times 208) = 550 \text{ kVA}$ .

The corresponding input-current is  
 $(208 \times 2640/2400) = 229 \text{ A}$ .

The ratio of turns in this case is given by

$$k = 2640/2400 = 1.1$$

With the step-up job, and  $k = 1.1$

$$\frac{\text{Rating of Auto-transformer}}{\text{Rating as two-winding transformer}} = \frac{k}{k-1} = \frac{1.1}{0.1}$$

This gives the rating as auto-transformer of 550 kVA.

At unity power-factor, the rated load = 550 kW.

Out of this, the “*inductively*” transferred power

$$\begin{aligned} &= \text{Power handled by the common winding} \\ &= (2400 \text{ V}) \times (20.8 \text{ A}) \times 10^{-3} = 50 \text{ kW.} \\ &= \text{Rated output as a two-winding transformer.} \end{aligned}$$

$$\text{Remaining Power} = 550 \text{ kW} - 50 \text{ kW} = 500 \text{ kW.}$$

This power of 500 kW is “*conductively*” transferred as is clear from the division of currents at the input node. Out of the total current of 229 A from the source, 208 A goes straight to the output. The remaining current of 20.8 A is through the “*common*” and “*inductive*” path, as marked in the Fig. 32.67.

### 32.35. Parallel Operation of Single-phase Transformers

For supplying a load in excess of the rating of an existing transformer, a second transformer may be connected in parallel with it as shown in Fig. 32.68. It is seen that primary windings are connected to the supply bus bars and secondary windings are connected to the load bus-bars. In connecting two or more than two transformers in parallel, it is essential that their terminals of similar polarities are joined to the same bus-bars as in Fig. 32.68. If this is not done, the two e.m.fs. induced in the secondaries which are paralleled with incorrect polarities, will act together in the local secondary circuit even when supplying no load and will hence produce the equivalent of a dead short-circuit as shown in Fig. 32.69.

Fig. 32.68

There are certain definite conditions which must be satisfied in order to avoid any local circulating currents and to ensure that the transformers share the common load in proportion to their kVA ratings. The conditions are :

1. Primary windings of the transformers should be suitable for the supply system voltage and frequency.
2. The transformers should be properly connected with regard to polarity.
3. The voltage ratings of both primaries and secondaries should be identical. In other words, the transformers should have the same turn ratio *i.e.* transformation ratio.
4. The percentage impedances should be equal in magnitude and have the same X/R ratio in order to avoid circulating currents and operation at different power factors.

- 5. With transformers having different kVA ratings, the equivalent impedances should be inversely proportional to the individual kVA rating if circulating currents are to be avoided.

Of these conditions, (1) is easily comprehended ; condition (2) is absolutely essential (otherwise paralleling with incorrect polarities will result in dead short-circuit). There is some latitude possible with conditions (3) and (4). If condition (3) is not exactly satisfied *i.e.* the two transformers have slightly different transformation or voltage ratios, even then parallel operation is possible. But due to inequality of induced e.m.fs. in secondaries, there will be even on no-load, some circulating current between them (and therefore between the primary windings also) when secondary terminals are connected in parallel. When secondaries are loaded, this localized circulating current will tend to produce unequal loading condition. Hence, it may be impossible to take full kVA output from the parallel connected group without one of the transformers becoming over-heated.

If condition (4) is not exactly satisfied *i.e.* impedance triangles are not identical in shape and size, parallel operation will still be possible, but the power factors at which the two transformers operate will be different from the power factor of the common load. Therefore, in this case, the two transformers will not share the load in proportion to their kVA ratings.

Fig. 32.69

It should be noted that the impedances of two transformers may differ in magnitude and in quality (*i.e.* ratio of equivalent resistance to reactance). It is worthwhile to distinguish between the **percentage** and **numerical** value of an impedance. For example, consider two transformers having ratings in the ratio 1 : 2. It is obvious that to carry double the current, the latter must have half the impedance of the former for the same regulation. For parallel operation, the regulation must be the same, this condition being enforced by the very fact of their being connected in parallel. It means that the currents carried by the two transformers are proportional to their ratings provided their **numerical** impedances are inversely proportional to these ratings and their **percentage** impedances are identical.

If the **quality** of the two percentage impedances is different (*i.e.* ratio of percentage resistance to reactance is different), then this will result in divergence of phase angle of the two currents, with the result that one transformer will be operating with a higher and the other with a lower power factor than that of the combined load.

(a) Case 1. Ideal Case

We will first consider the ideal case of two transformers having the same voltage ratio and having impedance voltage triangles identical in size and shape.

Let  $E$  be the no-load secondary voltage of each transformer and  $V_2$  the terminal voltage ;  $I_A$  and  $I_B$  the currents supplied by them and  $I$  the total current, lagging behind  $V_2$  by an angle  $\phi$  (Fig. 32.70(a))

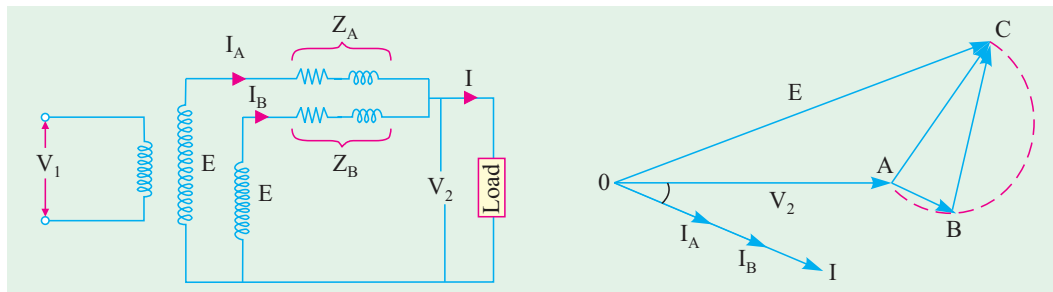

Fig. 32.70 (a)

Fig. 32.70 (b)

In Fig. 32.70 (b) a single triangle  $ABC$  represents the identical impedance voltage triangles of both the transformers. The currents  $I_A$  and  $I_B$  of the individual transformers are in phase with the load current  $I$  and are inversely proportional to the respective impedances. Following relations are obvious.

Also 
$$\mathbf{I} = \mathbf{I}_A + \mathbf{I}_B; \mathbf{V}_2 = \mathbf{E} - \mathbf{I}_A \mathbf{Z}_A = \mathbf{E} - \mathbf{I}_B \mathbf{Z}_B = \mathbf{E} - \mathbf{I} \mathbf{Z}_{AB}$$

$$\mathbf{I}_A \mathbf{Z}_A = \mathbf{I}_B \mathbf{Z}_B \text{ or } \mathbf{I}_A / \mathbf{I}_B = \mathbf{Z}_B / \mathbf{Z}_A$$

$$\therefore \mathbf{I}_A = \mathbf{I} \mathbf{Z}_B / (\mathbf{Z}_A + \mathbf{Z}_B) \text{ and } \mathbf{I}_B = \mathbf{I} \mathbf{Z}_A / (\mathbf{Z}_A + \mathbf{Z}_B)$$

(b) Case 2. Equal Voltage Ratios

Let us assume that no-load voltages of both secondaries is the same i.e.  $E_A = E_B = E$ , and that the two voltages are coincident i.e. there is no phase difference between  $E_A$  and  $E_B$ , which would be true if the magnetising currents of the two transformers are not much different from each other. Under these conditions, both primaries and secondaries of the two transformers can be connected in parallel and there will circulate no current between them on *on-load*.

Fig. 32.71

However, if we neglect the magnetising admittances, the two transformers can be connected as shown by their equivalent circuits in Fig. 32.71. The vector diagram is shown in Fig. 32.72.

From Fig. 32.71 (a) or (b) it is seen that it represents two impedances in parallel. Considering all values *consistently with reference to secondaries*, let

- $Z_A, Z_B$  = impedances of the transformers
- $I_A, I_B$  = their respective currents
- $V_2$  = common terminal voltage
- $I$  = combined current

It is seen that  $I_A Z_A = I_B Z_B = I Z_{AB}$  ... (i)  
 where  $Z_{AB}$  is the combined impedance of  $Z_A$  and  $Z_B$  in parallel.

$1/Z_{AB} = 1/Z_A + 1/Z_B$

Hence  $Z_{AB} = Z_A Z_B / (Z_A + Z_B)$  ... (ii)

From equation (i), we get

$Z_A = I Z_{AB} Z_A = I Z_B / (Z_A + Z_B)$  and  $I_B = I Z_{AB} / Z_B = I Z_A / (Z_A + Z_B)$

Multiplying both sides by common terminal voltage  $V_2$ , we have

$V_2 I_A = V_2 I \frac{Z_B}{Z_A + Z_B}$ ; Similarly  $V_2 I_B = V_2 I \frac{Z_A}{Z_A + Z_B}$

Let  $V_2 I \times 10^{-3} = S$  - the combined load kVA. Then, the kVA carried by each transformer is

$S_A = S \frac{Z_B}{Z_A + Z_B} = S \frac{1}{1 + Z_A / Z_B}$  and  $S_B = S \frac{Z_A}{Z_A + Z_B} = S \frac{1}{1 + Z_B / Z_A}$  ... (iii)

Hence,  $S_A$  and  $S_B$  are obtained in magnitude as well as in phase from the above vectorial expressions.

The above problem may be solved graphically, although somewhat more laboriously. As shown in Fig. 32.72, drawn  $I_A$  and  $I_B$  with an angular difference of  $(\phi_A - \phi_B)$  and magnitude (according to some suitable scale) inversely proportional to the respective impedances. Vector sum of  $I_A$  and  $I_B$  gives total combined current  $I$ . The phase angle and magnitude of  $I$  will be known from the conditions of loading, so that angle  $\phi$

Fig. 32.72

between  $V_2$  and  $I$  will be known. Inserting this, the transformer currents  $I_A$  and  $I_B$  become known in magnitude and phase with respect to  $V_2$ .

**Note. (a)** In equation (iii) above, it is not necessary to use the ohmic values of resistances and reactances, because only impedance ratios are required.

**(b)** The two percentage impedances must be adjusted to the same kVA in the case of transformers of different rating as in Ex. 32.101.

**(c)** From equation (iii) above, it is seen that if two transformers having the same rating and the same transformation ratio are to share the load equally, then their impedances should be equal *i.e.* equal resistances and reactances and not numerical equality of impedances. In general, for transformers of different ratings but same transformation ratio, their equivalent impedances must be inversely proportional to their ratings if each transformer is to assume a load in proportion to its rating. For example, as said earlier, a transformer operating in parallel with another of twice the rating, must have an impedance twice that of the large transformer in order that the load may be properly shared between them.

**Example 32.96.** Two 1-phase transformers with equal turns have impedances of  $(0.5 + j3)$  ohm and  $(0.6 + j10)$  ohm with respect to the secondary. If they operate in parallel, determine how they will share a total load of 100 kW at p.f. 0.8 lagging? (Electrical Technology, Madras Univ. 1987)

**Solution.**  $Z_A = 0.5 + j3 = 3.04 \angle 80.6^\circ$      $Z_B = 0.6 + j10 = 10.02 \angle 86.6^\circ$

$$Z_A + Z_B = 1.1 + j13 = 13.05 \angle 85.2^\circ$$

Now, a load of 100 kW at 0.8 p.f. means a kVA of  $100/0.8 = 125$ . Hence,

$$S = 125 \angle -36.9^\circ$$

$$S_A = S \frac{Z_B}{Z_A + Z_B} = \frac{125 \angle -36.9^\circ \times 10.02 \angle 86.6^\circ}{13.05 \angle 85.2^\circ} = 96 \angle -35.5^\circ$$

= a load of  $96 \times \cos 35.5^\circ = 78.2$  kW

$$S_B = S \frac{Z_A}{Z_A + Z_B} = \frac{125 \angle -36.9^\circ \times 3.04 \angle 80.6^\circ}{13.05 \angle 85.2^\circ} = 29.1 \angle -41.5^\circ$$

= a load of  $29.1 \times \cos 41.5^\circ = 21.8$  kW

**Note.** Obviously, transformer A is carrying more than its due share of the common load.

**Example 32.97.** Two single-phase transformers A and B are connected in parallel. They have same kVA ratings but their resistances are respectively 0.005 and 0.01 per unit and their leakage reactances 0.05 and 0.04 per unit. If A is operated on full-load at a p.f. of 0.8 lagging, what will be the load and p.f. of B? (A.C. Machines-I, Jadavpur Univ. 1985)

**Solution.** In general,  $S_A = S \frac{Z_B}{Z_A + Z_B}$  and  $S_B = S \frac{Z_A}{Z_A + Z_B}$

where  $S$  is the total kVA supplied and  $Z_A$  and  $Z_B$  are the percentage impedances of these transformers.

$$\frac{S_B}{S_A} = \frac{Z_A}{Z_B}$$

Now,  $Z_A = 0.005 + j0.05$  per unit ; %  $Z_A = 0.5 + j5$  and %  $Z_B = 1 + j4$

Let  $S_A = S_A \angle -36.87^\circ$

where  $S_A$  represents the rating of transformer A (and also of B).

$$\begin{aligned} S_B &= S_A \angle -36.87^\circ \times \frac{(0.5 + j5)}{(1 + j4)} \\ &= S_A \angle -36.87^\circ \times \frac{20.7}{17} \angle 8.3^\circ = 1.22 S_A \angle -28.57^\circ \end{aligned}$$

It is obvious that transformer *B* is working **22%** over-load and its power factor is

$$\cos 28.57^\circ = \mathbf{0.878 \text{ (lag)}}$$

**Example 32.98.** Two 1-phase transformers *A* and *B* rated at 250 kVA each are operated in parallel on both sides. Percentage impedances for *A* and *B* are  $(1 + j6)$  and  $(1.2 + j4.8)$  respectively. Compute the load shared by each when the total load is 500 kVA at 0.8 p.f. lagging.

(Electrical Machines-II, Indore Univ. 1989)

**Solution.**

$$\frac{Z_A}{Z_A + Z_B} = \frac{1 + j6}{2.2 + j10.8} = 0.55 \angle 2.1^\circ; \quad \frac{Z_B}{Z_A + Z_B} = \frac{1.2 + j4.8}{2.2 + j10.8} = 0.45 \angle -2.5^\circ$$

$$S_A = S \frac{Z_B}{Z_A + Z_B} = 500 \angle -36.9^\circ \times 0.45 \angle -2.5^\circ = \mathbf{225 \angle -39.4^\circ}$$

$$S_B = S \frac{Z_A}{Z_A + Z_B} = 500 \angle -36.9^\circ \times 0.55 \angle 2.1^\circ = \mathbf{275 \angle -34.8^\circ}$$

Obviously, transformer *B* is overloaded to the extent of  $(275 - 250) \times 100/250 = 10\%$ . It carries  $(275/500) \times 100 = 55\%$  of the total load.

**Example 32.99.** Two 100-kW, single-phase transformers are connected in parallel both on the primary and secondary. One transformer has an ohmic drop of 0.5% at full-load and an inductive drop of 8% at full-load current. The other has an ohmic drop of 0.75% and inductive drop of 2%. Show how will they share a load of 180 kW at 0.9 power factor.

(Elect. Machines-I, Calcutta Univ. 1988)

**Solution.** A load of 180 kW at 0.9 p.f. means a kVA of  $180/0.9 = 200$

$$\therefore \text{Load } S = 200 \angle -25.8^\circ$$

$$\begin{aligned} \frac{Z_1}{Z_1 + Z_2} &= \frac{(0.5 + j8)}{(1.25 + j12)} = \frac{(0.5 + j8)(1.25 - j12)}{1.25^2 + 12^2} \\ &= \frac{96.63 + j4}{145.6} = \frac{96.65 \angle 2.4^\circ}{145.6} = 0.664 \angle 2.4^\circ \end{aligned}$$

$$\begin{aligned} \frac{Z_2}{Z_1 + Z_2} &= \frac{(0.75 + j4)(1.25 - j12)}{145.6} \\ &= \frac{48.94 - j4}{145.6} = \frac{49.1 \angle -5^\circ}{145.6} \\ &= 0.337 \angle -5^\circ \end{aligned}$$

$$S_1 = S \frac{Z_2}{Z_1 + Z_2} = 200 \angle -25.8^\circ \times 0.337 \angle -5^\circ = 67.4 \angle -30.8^\circ$$

$$\therefore \text{kW}_1 = 67.4 \times \cos 30.8^\circ = 67.4 \times 0.859 = 57.9 \text{ kW}$$

$$S_2 = 200 \angle -25.8^\circ \times 0.664 \angle 2.4^\circ = 132.8 \angle -23.4^\circ$$

$$\text{kW}_2 = 132.8 \times \cos 23.4^\circ = 132.8 \times 0.915 = 121.5 \text{ kW}$$

**Note.** Second transformer is working 21.5% over-load. Also, it shares 65.7% of the total load.

**Example 32.100.** A load of 200 kW at 0.85 power factor lagging is to be shared by two transformers *A* and *B* having the same ratings and the same transformation ratio. For transformer *A*, the full-load resistive drop is 1% and reactance drop 5% of the normal terminal voltage. For transformer *B* the corresponding values are : 2% and 6%. Calculate the load kVA supplied by each transformer.

**Solution.**  $Z_A = 1 + j5; Z_B = Z + j6$

$$\frac{Z_A}{Z_B} = \frac{1+j5}{2+j6} = 0.8 + j0.1; \quad \frac{Z_B}{Z_A} = \frac{2+j6}{1+j5} = 1.23 - j0.514$$

Load

$$\text{kVA} = \text{kW}/\text{p.f.} = 200/0.85 = 235$$

$$\begin{aligned} \text{kVA} = S &= 235(0.85 - j0.527) \\ &= 200 - j123.8 \quad (\because \cos \phi = 0.85; \sin \phi = 0.527) \end{aligned}$$

$$\begin{aligned} S_A &= S \frac{Z_B}{Z_A + Z_B} = S \frac{1}{1 + (Z_A/Z_B)} \\ &= \frac{200 - j123.8}{1 + (0.8 + j0.1)} = \frac{200 - j123.8}{1.8 + j0.1} = 107.3 - j74.9 \end{aligned}$$

$$S_A = \sqrt{(107.3^2 + 74.9^2)} = 131; \quad \cos \phi_A = 107.3/131 = 0.82 \text{ (lag)}$$

Similarly

$$\begin{aligned} S_B &= S \frac{Z_A}{Z_A + Z_B} = S \frac{1}{1 + (Z_B/Z_A)} \\ &= \frac{200 - j123.8}{1 + (1.23 - j0.514)} = \frac{200 - j123.8}{2.23 - j0.154} = 93 - j49 \end{aligned}$$

$$\therefore S_B = \sqrt{(93^2 + 49^2)} = 105; \quad \cos \phi_B = 93/105 = 0.888 \text{ (lag)}$$

(As a check,  $S = S_A + S_B = 131 + 105 = 236$ . The small error is due to approximations made in calculations.)

**Example 32.101.** Two 2,200/110-V, transformers are operated in parallel to share a load of 125 kVA at 0.8 power factor lagging. Transformers are rated as below :

A : 100 kVA ; 0.9% resistance and 10% reactance

B : 50 kVA ; 1.0% resistance and 5% reactance

Find the load carried by each transformer.

(Elect. Technology, Utkal Univ. 1989)

**Solution.** It should be noted that the percentages given above refer to different ratings. As pointed out in Art. 32.35, these should be adjusted to the same basic kVA, say, 100 kVA.

$$\begin{aligned} \% Z_A &= 0.9 + j10; \quad \% Z_B = (100/50)(1 + j5) = (2 + j10) \\ \frac{Z_A}{Z_A + Z_B} &= \frac{0.9 + j10}{(2.9 + j20)} = \frac{(0.9 + j10)(2.9 - j20)}{2.9^2 + 20^2} \\ &= \frac{(202.6 + j11)}{408.4} = \frac{202.9 \angle 3.1^\circ}{408.4} = 0.4968 \angle 3.1^\circ \\ \frac{Z_B}{Z_A + Z_B} &= \frac{(2 + j10)(2.9 - j20)}{408.4} = \frac{206 - j11}{408.4} \\ &= \frac{206.1 \angle -3.1^\circ}{408.4} = 0.504 \angle -3.1^\circ \end{aligned}$$

$$\text{Also} \quad \cos \phi = 0.8, \phi = \cos^{-1}(0.8) = 36.9^\circ$$

$$S_A = S \frac{Z_B}{Z_A + Z_B} = 125 \angle -36.9^\circ \times 0.504 \angle -3.1^\circ = 63 \angle -40^\circ$$

$$S_B = S \frac{Z_A}{Z_A + Z_B} = 125 \angle -36.9^\circ \times 0.4968 \angle 3.1^\circ = 62.1 \angle -33.8^\circ$$

**Example 32.102.** A 500-kVA transformer with 1% resistance and 5% reactance is connected in parallel with a 250-kVA transformer with 1.5% resistance and 4% reactance. The secondary voltage of each transformer is 400 V on no-load. Find how they share a load of 750-kVA at a p.f. of 0.8 lagging. **(Electrical Machinery-I, Madras Univ. 1987)**

**Solution.** It may be noted that percentage drops given above refer to different ratings. These should be adjusted to the same basic kVA i.e. 500 kVA.

$$\begin{aligned} \% Z_A &= 1 + j5 = 5.1 \angle 78.7^\circ; \% Z_B = \left(\frac{500}{250}\right)(1.5 + j4) = 3 + j8 = 8.55 \angle 69.4^\circ \\ \% (Z_A + Z_B) &= 4 + j13 = 13.6 \angle 72.9^\circ; S = 750 \angle -36.9^\circ \\ S_A &= S \frac{Z_B}{Z_A + Z_B} = \frac{750 \angle -36.9^\circ \times 8.55 \angle 69.4^\circ}{13.6 \angle 72.9^\circ} = 470 \angle -40.4^\circ \\ &= 470 \text{ kVA at p.f. of } 0.762 \text{ lagging} \\ S_B &= S \frac{Z_A}{Z_A + Z_B} = \frac{750 \angle -36.9^\circ \times 5.1 \angle 78.7^\circ}{13.6 \angle 72.9^\circ} = 280 \angle -31.1^\circ \\ &= 280 \text{ kVA at p.f. } 0.856 \text{ lagging} \end{aligned}$$

**Note.** The above solution has been attempted vectorially, but in practice, the angle between  $I_A$  and  $I_B$  is so small that if instead of using vectorial expressions, arithmetic expressions were used, the answer would not be much different. In most cases, calculations by both vectorial and arithmetical methods generally yield results that do not differ sufficiently to warrant the more involved procedure by the vector solution. The above example will now be attempted arithmetically :

$$\begin{aligned} Z_A &= 5.1 \Omega, Z_B = 8.55 \Omega; I_A/I_B = Z_B/Z_A = 8.55/5.1 = 1.677 \therefore I_A = 1.677 I_B \\ \text{Total current} &= 750,000/400 = 1875 \text{ A} \\ I &= I_A + I_B; 1875 = 1.677 I_B + I_B = 2.677 I_B \therefore I_B = 1875/2.677 \\ \therefore S_B &= 400 \times 1875/2.677 \times 100 = 280 \text{ kVA} \\ I_A &= 1.677 \times 1875/2.677 \\ S_A &= 400 \times 1.677 \times 1875/2.677 \times 1000 = 470 \text{ kVA} \end{aligned}$$

**Example 32.103.** Two single-phase transformers A and B of equal voltage ratio are running in parallel and supply a load of 1000 A at 0.8 p.f. lag. The equivalent impedances of the two transformers are  $(2 + j3)$  and  $(2.5 + j5)$  ohms respectively. Calculate the current supplied by each transformer and the ratio of the kW output of the two transformers. **(Electrical Machines-I, Bombay Univ. 1986)**

**Solution.**  $Z_A = (2 + j3), Z_B = (2.5 + j5)$

Now,  $\frac{I_A}{I_B} = \frac{Z_B}{Z_A} = \frac{2.5 + j5}{2 + j3} = (1.54 + j0.2); I_A = I_B (1.54 + j0.2)$

Taking secondary terminal voltage as reference vector, we get

$$\begin{aligned} I &= 1000(0.8 - j0.6) = 800 - j600 = 200(4 - j3) \\ \text{Also, } I &= I_A + I_B = I_B(1.54 + j0.2) + I_B(2.54 + j0.2) \\ \therefore 200(4 - j3) &= I_B(2.54 + j0.2); I_B = 294.6 - j259.5 = 392.6 \angle -41.37^\circ \\ I_A = I_B(1.54 + j0.2) &= (294.6 - j259.5)(1.54 + j0.2) = 505.6 - j340.7 \\ &= 609.7 \angle -33.95^\circ \end{aligned}$$

The ratio of the kW output is given by the ratio of the in-phase components of the two currents.

$$\frac{\text{output of } A}{\text{output of } B} = \frac{505.6}{294.6} = \frac{1.7}{1}$$

**Note.** Arithmetic solution mentioned above could also be attempted.

**Example 32.104.** Two transformers A and B, both of no-load ratio 1,000/500-V are connected in parallel and supplied at 1,000 V. A is rated at 100 kVA, its total resistance and reactance being 1% and 5% respectively, B is rated at 250 kVA, with 2% resistance and 2% reactance. Determine the load on each transformer and the secondary voltage when a total load of 300 kVA at 0.8 power factor lagging is supplied.

**Solution.** Let the percentage impedances be adjusted to the common basic kVA of 100.

Then  $\%Z_A = (1 + j5)$ ;  $\%Z_B = (100/250)(2 + j2) = (0.8 + j0.8)$

$$\frac{Z_A}{Z_A + Z_B} = \frac{1 + j5}{(1.8 + j5.8)} = 0.839 \angle 5.9^\circ$$

$$\frac{Z_B}{Z_A + Z_B} = \frac{0.8 + j0.8}{(1.8 + j5.8)} = 0.1865 \angle -27.6^\circ$$

Now,  $S = 300 \angle -36.9^\circ = 240 - j180$

$$S_A = S \cdot \frac{Z_B}{Z_A + Z_B} = 300 \angle -36.9^\circ \times 0.1865 \angle -27.6^\circ = 55.95 \angle -64.5^\circ$$

$$S_B = S \cdot \frac{Z_A}{Z_A + Z_B} = 300 \angle -36.9^\circ \times 0.839 \angle 5.9^\circ = 251.7 \angle -31^\circ$$

Since  $Z_A$  and  $Z_B$  are in parallel, their combined impedance on 100 kVA basis is

$$Z_{AB} = \frac{Z_A Z_B}{Z_A + Z_B} = \frac{(1 + j5)(0.8 + j0.8)}{(1.8 + j5.8)} = 0.6 + j0.738$$

Percentage drop over  $Z_{AB}$  is  $= (0.6 \times 240/100) + (0.738 \times 180/100) = 1.44 + 1.328 = 2.768\%$

$$\therefore V_2 = \left( 500 - \frac{500 \times 2.768}{100} \right) = \mathbf{486.12 \text{ V}}$$

**Example 32.105.** Two 1- $\phi$  transformers are connected in parallel at no-load. One has a turn ratio of 5,000/440 and a rating of 200 kVA, the other has a ratio of 5,000/480 and a rating of 350 kVA. The leakage reactance of each is 3.5%.

What is the no-load circulation current expressed as a percentage of the nominal current of the 200 kVA transformer.

**Solution.** The normal currents are

$$200 \times 10^3 / 440 = 455 \text{ A and } 350 \times 10^3 / 480 = 730 \text{ A}$$

Reactances seen from the secondary side are

$$\frac{3.5}{100} \times \frac{440}{455} = 0.034 \Omega, \quad \frac{3.5}{100} \times \frac{480}{730} = 0.023 \Omega$$

The difference of induced voltage is 40 V. The circulating current is

$$I_C = 40 / 0.057 = 704 \text{ A} = \mathbf{1.55 \text{ times}}$$
 the normal current of 200 kVA unit.

### Tutorial Problems 32.6

- Two single-phase transformers A and B of equal voltage ratio are running in parallel and supplying a load requiring 500 A at 0.8 power factor lagging at a terminal voltage of 400 V. The equivalent impedances of the transformers, as referred to secondary windings, are  $(2 + j3)$  and  $(2.5 + j5)$  ohm. Calculate the current supplied by each transformer.

**(Note.** The student is advised to try by arithmetic method also).  $[I_A = 304 \text{ A} ; I_B = 197 \text{ A}]$

- Two single-phase transformers A and B are operating in parallel and supplying a common load of 1000 kVA at 0.8 p.f. lagging. The data regarding the transformers is as follows :

Transformer	Rating	%Resistance	% Reactance
A	750 kVA	3	5
B	500 kVA	2	4

Determine the loading of each transformer.  $[S_A = 535 \angle -34.7^\circ ; S_B = 465 \angle -39.3^\circ]$

3. Two transformers *A* and *B* give the following test results. With the low-tension side short-circuited, *A* takes a current of 10 A at 200 V, the power input being 1000 W. Similarly, *B* takes 30 A at 200 V ; the power input being 1,500 W. On open circuit, both transformers give a secondary voltage of 2200 when 11,000 volts are applied to the primary terminals. These transformers are connected in parallel on both high tension and low tension sides. Calculate the current and power in each transformer when supplying a load of 200 A at 0.8 power factor lagging. The no-load currents may be neglected.

(Hint : Calculate  $Z_A$  and  $Z_B$  from S.C. test data)

$[I_A = 50.5 \text{ A}, P_A = 100 \text{ kW} ; I_B = 151 \text{ A}, P_B = 252 \text{ kW}]$  (London University)

4. Two 6600/250-V transformers have the following short-circuit characteristics : Applied voltage 200 V, current 30 A, power input 1,200 W for one of the transformers ; the corresponding data for the other transformer being 120 V, 20 A and 1,500 W. All values are measured on the H.V. side with the L.V. terminals short circuited. Find the approximate current and the power factor of each transformer when working in parallel with each other on the high and low voltage sides and taking a total load of 150 kW at a p.f. of 0.8 lagging from the high voltage bus-bars.

$[I_A = 13.8 \text{ A}, \cos \phi_A = 0.63 ; I_B = 15.35 \text{ A}, \cos \phi_B = 0.91]$  (Electrical Engg-IV, Baroda Univ. 1978)

5. Two 11,000/2,200-V, 1-phase transformers are connected in parallel to supply a total load of 200 at 0.8 p.f. lagging at 2,200 V. One transformer has an equivalent resistance of 0.4  $\Omega$  and equivalent reactance of 0.8  $\Omega$  referred to the low-voltage side. The other has equivalent resistance of 0.1  $\Omega$  and a reactance of 0.3  $\Omega$ . Determine the current and power supplied by each transformer.

$[52 \text{ A} ; 148 \text{ A} ; 99 \text{ A} ; 252 \text{ kW}]$

6. A 2,000-kVA transformer (*A*) is connected in parallel with a 4,000-kVA transformer (*B*) to supply a 3-phase load of 5,000 kVA at 0.8 p.f. lagging. Determine the kVA supplied by each transformer assuming equal no-load voltages. The percentage volt drops in the windings at the rated loads are as follows :

Transformer *A* : resistance 2% ; reactance 8%

Transformer *B* : resistance 1.6% ; reactance 3%

$[A : 860 \text{ kVA}, 0.661 \text{ lag} ; B : 4170 \text{ kVA}, 0.824 \text{ lag}]$  (A.C. Machines-I, Jadavpur Univ. 1979)

7. Two single-phase transformers work in parallel on a load of 750 A at 0.8 p.f. lagging. Determine secondary voltage and the output and power factor of each transformer. Test data are :

Open circuit : 11,00/13,300 V for each transformer

Short circuit : with h.v. winding short-circuit

Transformer *A* : secondary input 200 V, 400 A, 15 kW

Transformer *B* : secondary input 100 V, 400 A, 20 kW

$[3,190 \text{ VA} ; 80 \text{ kVA}, 0.65 \text{ lag} ; B : 1,615 \text{ kVA} ; 0.86 \text{ lag}]$

(c) Case 3. Unequal Voltage Ratios

In this case, the voltage ratios (or transformation ratios) of the two transformers are different. It means that their no-load secondary voltages are unequal. Such cases can be more easily handled by phasor algebra than graphically.

Let  $E_A, E_B$  = no-load secondary e.m.f.s of the two transformers.

$Z_L$  = load impedance across the secondary.

The equivalent circuit and vector diagram are also shown in Fig. 32.73 and 32.74.

Fig. 32.73

It is seen that even when secondaries are on no-load, there will be some cross-current in them because of inequality in their induced e.m.fs. This circulating current  $I_C$  is given by

$$I_C = (E_A - E_B)/(Z_A + Z_B) \quad \dots(i)$$

As the induced e.m.fs. of the two transformers are equal to the total drops in their respective circuits.

$$\therefore Z_A = I_A Z_A + V_2 ; E_B = I_B Z_B + V_2$$

Now,  $V_2 = I Z_L = (I_A + I_B) Z_L$

where  $Z_L =$  load impedance

$$E_A = I_A Z_A + (I_A + I_B) Z_L \quad \dots(ii)$$

$$E_B = I_B Z_B + (I_A + I_B) Z_L \quad \dots(iii)$$

$$\therefore E_A - E_B = I_A Z_A - I_B Z_B \quad \dots(iv)$$

$$I_A = [(E_A - E_B) + I_B Z_B]/Z_A$$

Substituting this value of  $I_A$  in equation (iii), we get

$$\begin{aligned} E_B &= I_B Z_B + [(E_A - E_B) + I_B Z_B]/Z_A + I_B Z_L \\ I_B &= [E_B Z_A - (E_A - E_B) Z_L]/[Z_A Z_B + Z_L(Z_A + Z_B)] \end{aligned} \quad \dots(v)$$

From the symmetry of the expression, we get

$$I_A = [E_A Z_B + (E_A - E_B) Z_L]/[Z_A Z_B + Z_L(Z_A + Z_B)] \quad \dots(vi)$$

Also,  $I = I_A + I_B = \frac{E_A Z_B + E_B Z_A}{Z_A Z_B + Z_L(Z_A + Z_B)}$

By multiplying the numerator and denominator of this equation by  $1/Z_A Z_B$  and the result by  $Z_L$  we get

$$V_2 = I Z_L = \frac{E_A/Z_A + E_B/Z_B}{1/Z_A + 1/Z_B + 1/Z_L}$$

The two equations (v) and (vi) then give the values of secondary currents. The primary currents may be obtained by the division of transformation ratio *i.e.*  $K$  and by addition (if not negligible) of the no-load current. Usually,  $E_A$  and  $E_B$  have the same phase (as assumed above) but there may be some phase difference between the two due to some difference of internal connection in parallel of a star/star and a star/delta 3-phase transformers.

If  $Z_A$  and  $Z_B$  are small as compared to  $Z_L$  *i.e.* when the transformers are not operated near short-circuit conditions, then equations for  $I_A$  and  $I_B$  can be put in a simpler and more easily under-standable form. Neglecting  $Z_A Z_B$  in comparison with the expression  $Z_L(Z_A + Z_B)$ , we have

$$I_A = \frac{E_A Z_B}{Z_L(Z_A + Z_B)} + \frac{E_A - E_B}{Z_A + Z_B} \quad \dots(vii)$$

$$I_B = \frac{E_B Z_A}{Z_L(Z_A + Z_B)} - \frac{E_A - E_B}{Z_A + Z_B} \quad \dots(viii)$$

The physical interpretation of the second term in equations (vii) and (viii) is that it represents the cross-current between the secondaries. The first term shows how the actual load current divides between the loads. The value of current circulating in transformer secondaries (even when there is no-load) is given by\*  $I_C = (E_A - E_B)/(Z_A + Z_B)$  assuming that  $E_A > E_B$ . It lags behind  $E_A$  by an angle  $\alpha$  given by  $\tan \alpha = (X_A + X_B)/(R_A + R_B)$ . If  $E_A + E_B$  the ratios of the currents are inversely as the impedances (numerical values).

\* Under load conditions, the circulating current is

$$I_C = \frac{E_A - E_B}{Z_A + Z_B + Z_A Z_B/Z_L}$$

If  $Z_L = \infty$  *i.e.* on open-circuit, the expression reduces to that given above.

Fig. 32.74

If in Eq. (iv) we substitute  $\mathbf{I}_B = \mathbf{I} - \mathbf{I}_A$  and simplify, we get

$$\mathbf{I}_A = \frac{\mathbf{I}Z_B}{Z_A + Z_B} + \frac{\mathbf{E}_A - \mathbf{E}_B}{Z_A + Z_B} \quad \dots(ix)$$

Similarly, if we substitute  $\mathbf{I}_A = \mathbf{I} - \mathbf{I}_B$  and simplify, then

$$\mathbf{I}_B = \frac{\mathbf{I}Z_A}{Z_A + Z_B} + \frac{\mathbf{E}_A - \mathbf{E}_B}{Z_A + Z_B} \quad \dots(x)$$

In a similar manner, value of terminal voltage  $V_2$  is given by

$$V_2 = \mathbf{I}Z_L = \frac{\mathbf{E}_A Z_B + \mathbf{E}_B Z_A - \mathbf{I}Z_A Z_B}{Z_A + Z_B} \quad \dots(xi)$$

These expressions give the values of transformer currents and terminal voltage in terms of the load current. The value of  $V_2$  may also be found as under :

As seen from Fig. 30.70.

$$\begin{aligned} \mathbf{I}_A &= (\mathbf{E}_A - V_2)/Z_A = (\mathbf{E}_A - V_2)\mathbf{Y}_A; \mathbf{I}_B = (\mathbf{E}_B - V_2)\mathbf{Y}_B \\ \mathbf{I} &= V_2\mathbf{Y}_L = \mathbf{I}_A + \mathbf{I}_B \text{ or } V_2\mathbf{Y}_L = (\mathbf{E}_A - V_2)\mathbf{Y}_A + (\mathbf{E}_B - V_2)\mathbf{Y}_B \end{aligned}$$

$$\therefore V_2(\mathbf{Y}_L + \mathbf{Y}_A + \mathbf{Y}_B) = \mathbf{E}_A\mathbf{Y}_A + \mathbf{E}_B\mathbf{Y}_B \text{ or } V_2 = \frac{\mathbf{E}_A\mathbf{Y}_A + \mathbf{E}_B\mathbf{Y}_B}{\mathbf{Y}_L + \mathbf{Y}_A + \mathbf{Y}_B} \quad \dots(xii)$$

Eq. (xi) gives  $V_2$  in terms of load current. But if only load kVA is given, the problem becomes more complicated and involves the solution of a quadratic equation in  $V_2$ .

Now,  $\mathbf{S} = V_2\mathbf{I}$ . When we substitute this value of  $\mathbf{I}$  in Eq. (xi), we get

$$V_2 = \frac{\mathbf{E}_A Z_B + \mathbf{E}_B Z_A - \mathbf{S}Z_A Z_B / V_2}{(Z_A + Z_B)}$$

$$\text{or } V_2^2(Z_A + Z_B) - V(\mathbf{E}_A Z_B + \mathbf{E}_B Z_A) + \mathbf{S}Z_A Z_B = 0$$

When  $V_2$  becomes known, then  $\mathbf{I}_A$  and  $\mathbf{I}_B$  may be directly found from

$$V_2 = \mathbf{E}_A - \mathbf{I}_A Z_A \text{ and } V_2 = \mathbf{E}_B - \mathbf{I}_B Z_B.$$

**Note.** In the case considered above, it is found more convenient to work with numerical values of impedances instead of % values.

**Example 32.106.** Two transformers A and B are joined in parallel to the same load. Determine the current delivered by each transformer having given : open-circuit e.m.f. 6600 V for A and 6,400 V for B. Equivalent leakage impedance in terms of the secondary =  $0.3 + j3$  for A and  $0.2 + j1$  for B. The load impedance is  $8 + j6$ . (Elect. Machines-I, Indore Univ. 1987)

**Solution.** 
$$\mathbf{I}_A = \frac{\mathbf{E}_A Z_B + (\mathbf{E}_A - \mathbf{E}_B)Z_L}{Z_A Z_B + Z_L(Z_A + Z_B)}$$

Here  $\mathbf{E}_A = 6,600 \text{ V}$  ;  $\mathbf{E}_B = 6,400 \text{ V}$  ;  $Z_L = 8 + j6$  ;  $Z_A = 0.3 + j3$  ;  $Z_B = 0.2 + j1$

$$\mathbf{I}_A = \frac{6600(0.2 + j1) + (6600 - 6400)(8 + j6)}{(0.3 + j3)(0.2 + j1) + (8 + j6)(0.3 + j3 + 0.2 + j1)}$$

$$117 - j156 = 195 \text{ A in magnitude}$$

Similarly,

$$\begin{aligned} \mathbf{I}_B &= \frac{\mathbf{E}_B Z_A - (\mathbf{E}_A - \mathbf{E}_B)Z_L}{Z_A Z_B + Z_L(Z_A + Z_B)} \\ &= \frac{6400(0.3 + j3) - (6600 - 6400)(8 + j6)}{(0.3 + j3) + (0.2 + j1)(8 + j6) + (0.5 + j4)} \\ &= 349 - j231 = 421 \text{ A (in magnitude)} \end{aligned}$$

**Example 32.107.** Two 1- $\phi$  transformers, one of 100 kVA and the other of 50 kVA are connected in parallel to the same bus-bars on the primary side, their no-load secondary voltages being 1000 V and 950 V respectively. Their resistances are 2.0 and 2.5 per cent respectively and their reactances 8 and 6 per cent respectively. Calculate no-load circulating current in the secondaries.

(Adv. Elect Machines, A.M.I.E. Sec. B, 1991)

**Solution.** The circuit connections are shown in Fig. 32.75.

**1st transformer**

Normal secondary current =  $100,000/1000 = 100$  A

$$R_A = \frac{1000 \times 2.0}{100 \times 100} = 0.2 \Omega ; X_A = \frac{1000 \times 8}{100 \times 100} = 0.8 \Omega$$

**2nd Transformer**

Normal secondary current =  $50,000/950 = 52.63$  A

$$R_B = 950 \times 2.5/100 \times 52.63 = 0.45 \Omega$$

$$X_B = 850 \times 6/100 \times 52.63 = 1.08 \Omega$$

Combined impedance of the two secondaries is

$$Z = \sqrt{(R_A + R_B)^2 + (X_A + X_B)^2}$$

$$= \sqrt{0.65^2 + 1.88^2} = 1.99 \Omega$$

$$\therefore I_c = (1000 - 950)/1.99 = 25.1 \text{ A} ; \alpha = \tan^{-1}(1.88/0.65) = 71^\circ$$

Fig. 32.75

**Example 32.108.** Two single-phase transformers, one of 1000-kVA and the other of 500-kVA are connected in parallel to the same bus-bars on the primary side ; their no-load secondary voltages being 500 V and 510 V respectively. The impedance voltage of the first transformer is 3% and that of the second 5%. Assuming that ratio of resistance to reactance is the same and equal to 0.4 in each. What will be the cross current when the secondaries are connected in parallel ?

(Electrical Machines-I, Madras Univ. 1985)

**Solution.** Let us first determine the ohmic value of the two impedances. Also, let the secondary voltage be 480 V\*.

Full-load  $I_A = 1000 \times 1000/480 = 2083$  A ; F.L.  $I_B = 500 \times 1000/480 = 1042$  A

$$Z_A = \frac{\%Z_A \times E_A}{100 \times I_A} = \frac{9 \times 500}{100 \times 2083} = 0.0072 \Omega$$

$$Z_B = \frac{5 \times 510}{100 \times 1042} = 0.0245 \Omega$$

$$I_C = \frac{E_B - E_A}{Z_A + Z_B} = \frac{510 - 500}{(0.0072 + 0.0245)} = 315.4 \text{ A}$$

**Note.** Since the value of X/R is the same for the two transformers, there is no phase difference between  $E_A$  and  $E_B$ .

**Example 32.109.** Two transformers A and B of ratings 500 kVA and 250 kVA are supplying a load kVA of 750 at 0.8 power factor lagging. Their open-circuit voltages are 405V and 415 V respectively. Transformer A has 1% resistance and 5% reactance and transformer B has 1.5% resistance and 4% reactance. Find (a) cross-current in the secondaries on no-load and (b) the load shared by each transformer.

\* Though it is chosen arbitrarily, its value must be less than either of the two no-load e.m.fs.

**Solution.** As said earlier, it is more convenient to work with ohmic impedances and for that purpose, we will convert percentage value into numerical values by assuming 400 volt as the terminal voltage (this value is arbitrary but this assumption will not introduce appreciable error).

$$\text{Now } I_A R_A = 1\% \text{ of } 400 \quad \therefore R_A = \frac{1}{100} \times \frac{400}{1250} = 0.0032 \Omega$$

$$\text{where } I_A = 500,000/400 = 1250 \text{ A}$$

$$I_A X_A = 5\% \text{ of } 400; X_A = \frac{5}{100} \times \frac{400}{1250} = 0.016 \Omega \text{ (i.e. } X_A = 5R_A)$$

In a similar way, we can find  $R_B$  and  $X_B$ ;  $R_B = 0.0096 \Omega$ ;  $X_B = 0.0256 \Omega$

$$\therefore \mathbf{Z}_A = 0.0032 + j0.016 = 0.0163 \angle 78.5^\circ; \mathbf{Z}_B = 0.0096 + j0.0256 = 0.0275 \angle 69.4^\circ$$

$$\mathbf{Z}_A + \mathbf{Z}_B = 0.0128 + j0.0416 = 0.0436 \angle 72.9^\circ$$

Next step is to calculate load impedance. Let  $\mathbf{Z}_L$  be the load impedance and  $V_2$  the terminal voltage which has been assumed as 400 V.

$$\therefore (V_2^2 / \mathbf{Z}_L) = 750 \angle -36.9^\circ$$

$$\therefore \mathbf{Z}_L = 400^2 \times 10^{-3} / 750 \angle -36.9^\circ = 0.214 \angle 36.9^\circ = (0.171 + j0.128) \Omega$$

$$(a) \quad \mathbf{I}_C = \frac{\mathbf{E}_A - \mathbf{E}_B}{\mathbf{Z}_A + \mathbf{Z}_B} = \frac{(405 - 415)}{0.0436 \angle 72.9^\circ} = -230 \angle -72.9^\circ$$

$$(b) \quad \mathbf{I}_A = \frac{405 \times 0.0275 \angle 69.4^\circ + (405 - 415) \times 0.214 \angle 36.9^\circ}{0.0163 \angle 78.5^\circ \times 0.0275 \angle 69.4^\circ + 0.214 \angle 36.9^\circ \times 0.0436 \angle 72.9^\circ} \\ = 970 \angle -35^\circ$$

$$\text{Similarly, } \mathbf{I}_B = \frac{415 \times 0.0163 \angle 78.5^\circ - (405 - 415) \times 0.214 \angle 36.9^\circ}{0.0163 \angle 78.5^\circ \times 0.0275 \angle 69.4^\circ + 0.214 \angle 36.9^\circ \times 0.0436 \angle 72.9^\circ}$$

$$\therefore \mathbf{S}_A = 400 \times 970 \times 10^{-3} \angle -35^\circ = 388 \angle -35^\circ \text{ kVA}; \cos \phi_A = \cos 35^\circ = 0.82 \text{ (lag)}$$

$$\mathbf{S}_B = 400 \times 875 \times 10^{-3} \angle 42.6^\circ = 350 \angle -42.6^\circ \text{ kVA}$$

$$\cos \phi_B = \cos 42.6^\circ = 0.736 \text{ (lag)}$$

**Example 32.110.** Two transformers A and B are connected in parallel to a load of  $(2 + j1.5)$  ohms. Their impedances in secondary terms are  $\mathbf{Z}_A = (0.15 + j0.5)$  ohm and  $\mathbf{Z}_B = (0.1 + j0.6)$  ohm. Their no-load terminal voltages are  $E_A = 207 \angle 0^\circ$  volt and  $E_B = 205 \angle 0^\circ$  volt. Find the power output and power factor of each transformer. **(Elect. Machines-I, Punjab Univ. 1991)**

**Solution.** Using the equations derived in Art. 30.34 (c), we have

$$\mathbf{I}_A = \frac{\mathbf{E}_A \mathbf{Z}_B + (\mathbf{E}_A - \mathbf{E}_B) \mathbf{Z}_L}{\mathbf{Z}_A \mathbf{Z}_B + \mathbf{Z}_L (\mathbf{Z}_A + \mathbf{Z}_B)}$$

$$\mathbf{Z}_A = (0.15 + j0.5) \Omega; \mathbf{Z}_B = (0.1 + j0.6) \Omega; \mathbf{Z}_L = (2 + j1.5) = 2.5 \angle 36.9^\circ$$

$$\therefore \mathbf{I}_A = \frac{207(0.1 + j0.6) + (207 - 205)(2 + j1.5)}{(0.15 + j0.5)(0.1 + j0.6) + (2 + j1.5)(0.25 + j1.1)} \\ = \frac{24.7 + j127.2}{-1.435 + j2.715} = \frac{129.7 \angle 79^\circ}{3.07 \angle 117.9^\circ} = 42.26 \angle -38.9^\circ \text{ A} = (32.89 - j26.55) \text{ A}$$

$$\mathbf{I}_B = \frac{\mathbf{E}_B \mathbf{Z}_A - (\mathbf{E}_A - \mathbf{E}_B) \mathbf{Z}_L}{\mathbf{Z}_A \mathbf{Z}_B + \mathbf{Z}_L (\mathbf{Z}_A + \mathbf{Z}_B)} = \frac{205(0.15 + j0.5) - 2(2 + j1.5)}{-1.435 + j2.715} = \frac{103 \angle 75^\circ}{3.07 \angle 117.9^\circ} \\ = 33.56 \angle -42.9^\circ = (24.58 - j22.84) \text{ A}$$

$$\text{Now } \mathbf{V}_2' = \mathbf{I} \mathbf{Z}_L = (\mathbf{I}_A + \mathbf{I}_B) \mathbf{Z}_L \\ = (57.47 - j49.39)(2 + j1.5) = 189 - j12.58 = 189.4 \angle -3.9^\circ$$

p.f. angle of transformer A =  $-3.9^\circ - (-38.9^\circ) = 35^\circ$

$\therefore$  p.f. of A =  $\cos 35^\circ = 0.818$  (lag) ; p.f. of B =  $\cos [-3.9^\circ - (-42.9^\circ)] = 0.776$  (lag)

Power output of transformer A is  $P_A = 189.4 \times 42.26 \times 0.818 = 6,548 \text{ W}$

Similarly,  $P_B = 189.4 \times 33.56 \times 0.776 = 4,900 \text{ W}$

**Example 32.111.** Two transformers have the following particulars :

	Transformer A	Transformer B
Rated current	200 A	600 A
Per unit resistance 0.02	0.025	
Per unit reactance	0.05	0.06
No-load e.m.f.	245 V	240 V

Calculate the terminal voltage when they are connected in parallel and supply a load impedance of  $(0.25 + j 0.1) \Omega$ . (Elect. Machines-I, Sd. Patel Univ. 1981)

**Solution.** Impedance in ohms =  $Z_{pu} \times \text{N.L. e.m.f./full-load current}$

$$Z_A = (245/200)(0.02 + j 0.05) = 0.0245 + j 0.0613 \Omega = 0.066 \angle 68.2^\circ$$

$$Z_B = (240/600)(0.025 + j 0.06) = 0.01 + j 0.024 \Omega = 0.026 \angle 67.3^\circ$$

$$Z = (0.25 + j 0.1) = 0.269 \angle 21.8^\circ ; Z_A + Z_B = 0.0345 + j 0.0853 = 0.092 \angle 68^\circ$$

$$Z_L(Z_A + Z_B) = 0.269 \times 0.092 \angle 89.8^\circ = 0.0247 \angle 89.8^\circ = (0 + j 0.0247)$$

$$Z_A Z_B = 0.066 \times 0.026 \angle 135.5^\circ = (-0.001225 + j 0.001201)$$

$$\therefore Z_A Z_B + Z_L(Z_A + Z_B) = (-0.00125 + j 0.259) = 0.0259 \angle 92.7^\circ$$

Let us take  $E_A$  as reference quantity.

Also  $E_B$  is in phase with  $E_A$  because transformers are in parallel on both sides.

$$E_A Z_B = 245(0.01 + j 0.0245) = 2.45 + j 5.87$$

$$E_B Z_A = 240(0.0245 + j 0.0613) = 5.88 + j 14.7$$

$$E_A Z_B + E_B Z_A = 8.33 + j 20.57 = 22.15 \angle 67.9^\circ$$

$$\text{Now, } I = \frac{E_A Z_B + E_B Z_A}{Z_A Z_B + Z_L(Z_A + Z_B)} = \frac{22.15 \angle 67.9^\circ}{0.0259 \angle 92.7^\circ} = 855 \angle -24.8^\circ$$

$$\therefore V_2 = I Z_L = 885 \angle -24.8^\circ \times 0.269 \angle 21.8^\circ = 230 - 3^\circ$$

### Tutorial Problems 29.1

1. A 1000-kVA and a 500-kVA, 1-phase transformers are connected to the same bus-bars on the primary side. The secondary e.m.fs. at no-load are 500 and 510 V respectively. The impedance voltage of the first transformer is 3.4% and of the second 5%. What cross-current will pass between them when the secondaries are connected together in parallel ? Assuming that the ratio of resistance to reactance is the same in each, what currents will flow in the windings of the two transformers when supplying a total load of 1200 kVA.

[(i) 290 A (ii) 1577 and 900 A] (City & Guilds, London)

2. Two transformers A and B are connected in parallel to supply a load having an impedance of  $(2 + j 1.5\Omega)$ . The equivalent impedances referred to the secondary windings are  $0.15 + j 0.5 \Omega$  and  $0.1 + j 0.6 \Omega$  respectively. The open-circuit e.m.f. of A is 207 V and of B is 205 V. Calculate (i) the voltage at the load (ii) the power supplied to the load (iii) the power output of each transformer and (iv) the kVA input to each transformer.

[(i) 189  $\angle -3.8^\circ$  V (ii) 11.5 kW (iii) 6.5 kW, 4.95 kW (iv) 8.7 kVA, 6.87 kVA]

## QUESTIONS AND ANSWERS ON TRANSFORMERS

**Q.1. How is magnetic leakage reduced to a minimum in commercial transformers ?**

**Ans.** By interleaving the primary and secondary windings.

**Q.2. Mention the factors on which hysteresis loss depends ?**

**Ans.** (i) Quality and amount of iron in the core (ii) Flux density and (iii) Frequency.

**Q.3. How can eddy current loss be minimised ?**

**Ans.** By laminating the core.

**Q.4. In practice, what determines the thickness of the laminae or stampings ?**

**Ans.** Frequency.

**Q.5. Does the transformer draw any current when its secondary is open ?**

**Ans.** Yes, no-load primary current.

**Q.6. Why ?**

**Ans.** For supplying no-load iron and copper losses in primary.

**Q.7. Is Cu loss affected by power factor ?**

**Ans.** Yes, Cu loss varies inversely with power factor.

**Q.8. Why ?**

**Ans.** Cu loss depends on current in the primary and secondary windings. It is well-known that current required is higher when power factor is lower.

**Q.9. What effects are produced by change in voltage ?**

- Ans.**
1. Iron loss.....varies approximately as  $V^2$ .
  2. Cu loss.....it also varies as  $V^2$  but decreases with an increase in voltage *if constant kVA output is assumed.*
  3. Efficiency.....for distribution transformers, efficiency at fractional loads decreases with increase in voltage while at full load or overload it increases with increase in voltage and *vice-versa.*
  4. Regulation.....it varies as  $V^2$  but decreases with increase in voltage *if constant kVA output is assumed.*
  5. Heating.....for constant kVA output, iron temperatures increase whereas Cu temperatures decrease with increase in voltages and *vice-versa.*

**Q. 10. How does change in frequency affect the operation of a given transformer ?**

- Ans.**
1. Iron loss .....increases with a decrease in frequency. A 60-Hz transformer will have nearly 11% higher losses when worked on 50Hz instead of 60 Hz. However, when a 25-Hz transformer is worked on 60 Hz, iron losses are reduced by 25%.
  2. Cu loss.....in distribution transformers, it is independent of frequency.
  3. Efficiency.....since Cu loss is unaffected by change in frequency, a given transformer efficiency is less at a lower frequency than at a higher one.
  4. Regulation.....regulation at unity power factor is not affected because *IR* drop is independent of frequency. Since reactive drop is affected, regulation at low power factors decreases with a decrease in frequency and *vice-versa.* For example, the regulation of a 25-Hz transformer when operated at 50-Hz and low power factor is much poorer.
  5. Heating.....since total loss is greater at a lower frequency, the temperature is increased with decrease in frequency.

## OBJECTIVE TESTS – 32

1. A transformer transforms
  - (a) frequency
  - (b) voltage
  - (c) current
  - (d) voltage and current.
2. Which of the following is not a basic element of a transformer ?
  - (a) core
  - (b) primary winding
  - (c) secondary winding
  - (d) mutual flux.
3. In an ideal transformer,
  - (a) windings have no resistance
  - (b) core has no losses
  - (c) core has infinite permeability
  - (d) all of the above.
4. The main purpose of using core in a transformer is to
  - (a) decrease iron losses
  - (b) prevent eddy current loss
  - (c) eliminate magnetic hysteresis
  - (d) decrease reluctance of the common magnetic circuit.
5. Transformer cores are laminated in order to
  - (a) simplify its construction
  - (b) minimise eddy current loss
  - (c) reduce cost
  - (d) reduce hysteresis loss.
6. A transformer having 1000 primary turns is connected to a 250-V a.c. supply. For a secondary voltage of 400 V, the number of secondary turns should be
 

(a) 1600	(b) 250
(c) 400	(d) 1250
7. The primary and secondary induced e.m.fs.  $E_1$  and  $E_2$  in a two-winding transformer are **always**
  - (a) equal in magnitude
  - (b) antiphase with each other
  - (c) in-phase with each other
  - (d) determined by load on transformer secondary.
8. A step-up transformer increases
 

(a) voltage	(b) current
(c) power	(d) frequency.
9. The primary and secondary windings of an ordinary 2-winding transformer **always** have
  - (a) different number of turns
  - (b) same size of copper wire
  - (c) a common magnetic circuit
  - (d) separate magnetic circuits.
10. In a transformer, the leakage flux of each winding is proportional to the current in that winding because
  - (a) Ohm's law applies to magnetic circuits
  - (b) leakage paths do not saturate
  - (c) the two windings are electrically isolated
  - (d) mutual flux is confined to the core.
11. In a two-winding transformer, the e.m.f. per turn in secondary winding is **always**.....the induced e.m.f. per turn in primary.
  - (a) equal to  $K$  times
  - (b) equal to  $1/K$  times
  - (c) equal to
  - (d) greater than.
12. In relation to a transformer, the ratio 20 : 1 indicates that
  - (a) there are 20 turns on primary one turn on secondary
  - (b) secondary voltage is  $1/20$ th of primary voltage
  - (c) primary current is 20 times greater than the secondary current.
  - (d) for every 20 turns on primary, there is one turn on secondary.
13. In performing the short circuit test of a transformer
  - (a) high voltage side is usually short circuited
  - (b) low voltage side is usually short circuited
  - (c) any side is short circuited with preference
  - (d) none of the above.

*(Elect. Machines, A.M.I.E. Sec. B, 1993)*
14. The equivalent resistance of the primary of a transformer having  $K = 5$  and  $R_1 = 0.1$  ohm when referred to secondary becomes.....ohm.
  - (a) 0.5
  - (b) 0.02
  - (c) 0.004
  - (d) 2.5
15. A transformer has negative voltage regulation when its load power factor is
  - (a) zero
  - (b) unity
  - (c) leading
  - (d) lagging.

- 16.** The primary reason why open-circuit test is performed on the low-voltage winding of the transformer is that it
- draws sufficiently large on-load current for convenient reading
  - requires least voltage to perform the test
  - needs minimum power input
  - involves less core loss.
- 17.** No-load test on a transformer is carried out to determine
- copper loss
  - magnetising current
  - magnetising current and no-load loss
  - efficiency of the transformer.
- 18.** The main purpose of performing open-circuit test on a transformer is to measure its
- Cu loss
  - core loss
  - total loss
  - insulation resistance.
- 19.** During short-circuit test, the iron loss of a transformer is negligible because
- the entire input is just sufficient to meet Cu losses only
  - flux produced is a small fraction of the normal flux
  - iron core becomes fully saturated
  - supply frequency is held constant.
- 20.** The iron loss of a transformer at 400 Hz is 10 W. Assuming that eddy current and hysteresis losses vary as the square of flux density, the iron loss of the transformer at rated voltage but at 50 Hz would be..... watt.
- 80
  - 640
  - 1.25
  - 100
- 21.** In operating a 400 Hz transformer at 50 Hz
- only voltage is reduced in the same proportion as the frequency
  - only kVA rating is reduced in the same proportion as the frequency
  - both voltage and kVA rating are reduced in the same proportion as the frequency
  - none of the above.
- 22.** The voltage applied to the h.v. side of a transformer during short-circuit test is 2% of its rated voltage. The core loss will be.....percent of the rated core loss.
- 4
  - 0.4
  - 0.25
  - 0.04
- 23.** Transformers are rated in kVA instead of kW because
- load power factor is often not known
  - kVA is fixed whereas kW depends on load p.f.
  - total transformer loss depends on volt-ampere
  - it has become customary.
- 24.** When a 400-Hz transformer is operated at 50 Hz its kVA rating is
- reduced to 1/8
  - increased 8 times
  - unaffected
  - increased 64 times.
- 25.** At relatively light loads, transformer efficiency is low because
- secondary output is low
  - transformer losses are high
  - fixed loss is high in proportion to the output
  - Cu loss is small.
- 26.** A 200 kVA transformer has an iron loss of 1 kW and full-load Cu loss of 2kW. Its load kVA corresponding to maximum efficiency is ..... kVA.
- 100
  - 141.4
  - 50
  - 200
- 27.** If Cu loss of a transformer at 7/8th full load is 4900 W, then its full-load Cu loss would be .....watt.
- 5600
  - 6400
  - 375
  - 429
- 28.** The ordinary efficiency of a given transformer is maximum when
- it runs at half full-load
  - it runs at full-load
  - its Cu loss equals iron loss
  - it runs slightly overload.
- 29.** The output current corresponding to maximum efficiency for a transformer having core loss of 100 W and equivalent resistance referred to secondary of 0.25  $\Omega$  is ..... ampere.
- 20
  - 25
  - 5
  - 400
- 30.** The maximum efficiency of a 100-kVA transformer having iron loss of 900 kW and F.L. Cu loss of 1600 W occurs at ..... kVA.
- 56.3
  - 133.3
  - 75
  - 177.7

31. The all-day efficiency of a transformer depends primarily on  
 (a) its copper loss  
 (b) the amount of load  
 (c) the duration of load  
 (d) both (b) and (c).
32. The marked increase in kVA capacity produced by connecting a 2 winding transformer as an autotransformer is due to  
 (a) increase in turn ratio  
 (b) increase in secondary voltage  
 (c) increase in transformer efficiency  
 (d) establishment of conductive link between primary and secondary.
33. The kVA rating of an ordinary 2-winding transformer is increased when connected as an autotransformer because  
 (a) transformation ratio is increased  
 (b) secondary voltage is increased  
 (c) energy is transferred both inductively and conductivity  
 (d) secondary current is increased.
34. The saving in Cu achieved by converting a 2-winding transformer into an autotransformer is determined by  
 (a) voltage transformation ratio  
 (b) load on the secondary  
 (c) magnetic quality of core material  
 (d) size of the transformer core.
35. An autotransformer having a transformation ratio of 0.8 supplies a load of 3 kW. The power transferred conductively from primary to secondary is.....kW.  
 (a) 0.6 (b) 2.4  
 (c) 1.5 (d) 0.27
36. The essential condition for parallel operation of two 1- $\phi$  transformers is that they should have the same  
 (a) polarity  
 (b) kVA rating  
 (c) voltage ratio  
 (d) percentage impedance.
37. If the impedance triangles of two transformers operating in parallel are not identical in shape and size, the two transformers will  
 (a) share the load unequally  
 (b) get heated unequally  
 (c) have a circulatory secondary current even when unloaded  
 (d) run with different power factors.
38. Two transformers A and B having equal outputs and voltage ratios but unequal percentage impedances of 4 and 2 are operating in parallel. Transformer A will be running over-load by ..... percent.  
 (a) 50 (b) 66  
 (c) 33 (d) 25

### Learning Objectives

- Three-phase Transformers
- Three-phase Transformer Connections
- Star/Star or Y/Y Connection
- Delta-Delta or Connection
- Wye/Delta or Y/ Connection
- Delta/Wye or /Y Connection
- Open-Delta or V-V Connection
- Power Supplied by V-V Bank
- Scott Connection or T-T Connection
- Three-phase to Two-Phase Conversion and vice-versa
- Parallel Operation of 3-phase Transformers
- Instrument Transformers
- Current Transformers
- Potential Transformers

## TRANSFORMER: THREE PHASE

Three phase transformers are used throughout industry to change values of three phase voltage and current. Three phase power is the most common way in which power is produced.

33.1. Three-Phase Transformer

Large scale generation of electric power is usually 3-phase at generated voltages of 13.2 kV or somewhat higher. Transmission is generally accomplished at higher voltages of 110, 132, 275, 400 and 750 kV for which purpose 3-phase transformers are necessary to step up the generated voltage to that of the transmission line. Next, at load centres, the transmission voltages are reduced to distribution voltages of 6,600, 4,600 and 2,300 volts. Further, at most of the consumers, the distribution voltages are still reduced to utilization voltages of 440, 220 or 110 volts. Years ago, it was a common

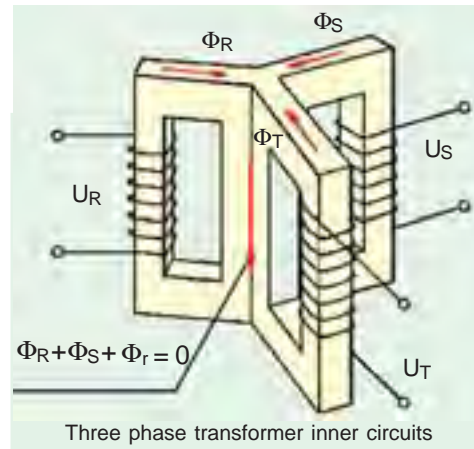

Fig. 33.1

practice to use suitably interconnected three single-phase transformers instead of a single 3-phase transformer. But these days, the latter is gaining popularity because of improvement in design and manufacture but principally because of better acquaintance of operating men with the three-phase type. As compared to a bank of single-phase transformers, the main advantages of a 3 phase transformer are that it occupies less floor space for equal rating, weighs less, costs about 15% less and further, that only one unit is to be handled and connected.

Like single-phase transformers, the three-phase transformers are also of the core type or shell type. The basic principle of a 3-phase transformer is illustrated in Fig. 33.1 in which only primary windings have been shown interconnected in star and put across 3-phase supply. The three cores are 120° apart and their empty legs are shown in

contact with each other. The centre leg, formed by these three, carries the flux produced by the three-phase currents  $I_R$ ,  $I_Y$  and  $I_B$ . As at any instant  $I_R + I_Y + I_B = 0$ , hence the sum of three fluxes is also zero. Therefore, it will make no difference if the common leg is removed. In that case any two legs will act as the return for the third just as in a 3-phase system any two conductors act as the return for the current

Fig. 33.2 (a)

in the third conductor. This improved design is shown in Fig. 33.2 (a) where dotted rectangles indicate the three windings and numbers in the cores and yokes represent the directions and magnitudes of fluxes at a particular instant. It will be seen that at any instant, the amount of 'up' flux in any leg is equal to the sum of 'down' fluxes in the other two legs. The core type transformers are usually wound with circular cylindrical coils.

In a similar way, three single-phase shell type transformers can be combined together to form a 3-phase shell type unit as shown in Fig. 33.2(b). But some saving in iron can be achieved in

Fig. 33.2 (b)

Fig. 33.3

constructing a single 3-phase transformer as shown in Fig. 33.3. It does not differ from three single-phase transformers put side by side. Saving in iron is due to the joint use of the magnetic paths between the coils. The three phases, in this case, are more independent than they are in the core type transformers, because each phase has a magnetic circuit independent of the other.

One main drawback in a 3-phase transformer is that if any one phase becomes disabled, then the whole transformer has to be ordinarily removed from service for repairs (the shell type may be operated open

$\Delta$  or Vee but this is not always feasible). However, in the case of a 3-phase bank of single-phase transformers, if one transformer goes out of order, the system can still be run open- $\Delta$  at reduced capacity or the faulty transformer can be readily replaced by a single spare.

### 33.2. Three-phase Transformer Connections

There are various methods available for transforming 3-phase voltages to higher or lower 3-phase voltages *i.e.* for handling a considerable amount of power. The most common connections are (i)  $Y-Y$  (ii)  $\Delta-\Delta$  (iii)  $Y-\Delta$  (iv)  $\Delta-Y$  (v) open-delta or  $V-V$  (vi) Scott connection or  $T-T$  connection.

### 33.3. Star/Star or Y/Y Connection

This connection is most economical for small, high-voltage transformers because the number of turns/phase and the amount of insulation required is minimum (as phase voltage is only  $1/\sqrt{3}$  of line voltage). In Fig. 33.4 a bank of 3 transformers connected in  $Y$  on both the primary and the secondary sides is shown. The ratio of line voltages on the primary and secondary sides is the same as the transformation ratio of each transformer. However, there is a phase shift of  $30^\circ$  between the phase voltages and line voltages both on the primary and secondary sides. Of course, line voltages on both sides as well as primary voltages are respectively in phase with each other.

respectively in phase with each other. **This connection works**

**satisfactorily only if the load is balanced.** With the unbalanced load to the neutral, the neutral point shifts thereby making the three line-to-neutral (*i.e.* phase) voltages unequal. The effect of unbalanced loads can be illustrated by placing a single load between phase (or coil)  $a$  and the neutral on the secondary side. The power to the load has to be supplied by primary phase (or coil)  $A$ . This primary coil  $A$  cannot supply the required power because it is in series with primaries  $B$  and  $C$  whose secondaries are open. Under these conditions, the primary coils  $B$  and  $C$  act as very high impedances so that primary coil  $A$  can obtain but very little current through them from the line. Hence, secondary coil  $a$  cannot supply any appreciable power. In fact, a very low resistance approaching a short-circuit may be connected between point  $a$  and the neutral and only a very small amount of current will flow. This, as said above, is due to the reduction of voltage  $E_{an}$  because of neutral shift. In other words, under short-circuit conditions, the neutral is pulled too much towards coil  $a$ . This reduces  $E_{an}$  but increases  $E_{bn}$  and  $E_{cn}$  (however line voltage  $E_{AB}$ ,  $E_{BC}$  and  $E_{CA}$  are unaffected). On the primary side,  $E_{AN}$  will be

Fig. 33.4

practically reduced to zero whereas  $E_{BN}$  and  $E_{CN}$  will rise to nearly full primary line voltage. This difficulty of shifting (or floating) neutral can be obviated by connecting the primary neutral (shown dotted in the figure) back to the generator so that primary coil  $A$  can take its required power from between its line and the neutral. It should be noted that if a single phase load is connected between the lines  $a$  and  $b$ , there will be a similar but less pronounced neutral shift which results in an overvoltage on one or more transformers.

Another advantage of stabilizing the primary neutral by connecting it to neutral of the generator is that it eliminates distortion in the secondary phase voltages. This is explained as follows. For delivering a sine wave of voltage, it is necessary to have a sine wave of flux in the core, but on account of the characteristics of iron, a sine wave of flux requires a third harmonic component in the exciting current. As the frequency of this component is thrice the frequency of the circuit, at any given instant, it tends to flow either towards or away from the neutral point in all the three transformers. If the primary neutral is isolated, the triple frequency current cannot flow. Hence, the flux in the core cannot be a sine wave and so the voltages are distorted. But if the primary neutral is earthed *i.e.* joined to the generator neutral, then this provides a path for the triple-frequency currents and e.m.fs. and the difficulty is overcome. Another way of avoiding this trouble of oscillating neutral is to provide each of the transformers with a third or tertiary winding of relatively low kVA rating. This tertiary winding is connected in  $\Delta$  and provides a circuit in which the triple-frequency component of the magnetising current can flow (with an isolated neutral, it could not). In that case, a sine wave of voltage applied to the primary will result in a sine wave of phase voltage in the secondary. As said above, the advantage of this connection is that insulation is stressed only to the extent of line to neutral voltage *i.e.* 58% of the line voltage.

### 33.4. Delta-Delta or $\Delta - \Delta$ Connection

This connection is economical for large, low-voltage transformers in which insulation problem is not so urgent, because it increases the number of turns/phase. The transformer connections and voltage triangles are shown in Fig. 33.5. The ratio of transformation between primary and secondary line voltage is exactly the same as that of each transformer. Further, the secondary voltage triangle  $abc$  occupies the same relative position as the primary voltage triangle  $ABC$  *i.e.* there is no angular displacement between the two. Moreover, there is no internal phase shift between phase and line voltages on either side as was the case in  $Y-Y$  connection. This connection has the following advantages :

1. As explained above, in order that the output voltage be sinusoidal, it is necessary that the magnetising current of the transformer must contain a third harmonic component. In this case, the third harmonic component of the magnetising current can flow in the  $\Delta$ -connected transformer primaries without flowing in the line wires. The three phases are  $120^\circ$  apart which is  $3 \times 120 = 360^\circ$  with respect to the third harmonic, hence it merely circulates in the  $\Delta$ . Therefore, the flux is sinusoidal which results in sinusoidal voltages.
2. No difficulty is experienced from unbalanced loading as was the case in  $Y-Y$  connection. The three-phase voltages remain practically constant regardless of load imbalance.
3. An added advantage of this connection is that if one transformer becomes disabled, the system can continue to operate in open-delta or in  $V-V$  although with reduced available capacity. The reduced capacity is 58% and not 66.7% of the normal value, as explained in Art. 33.7.

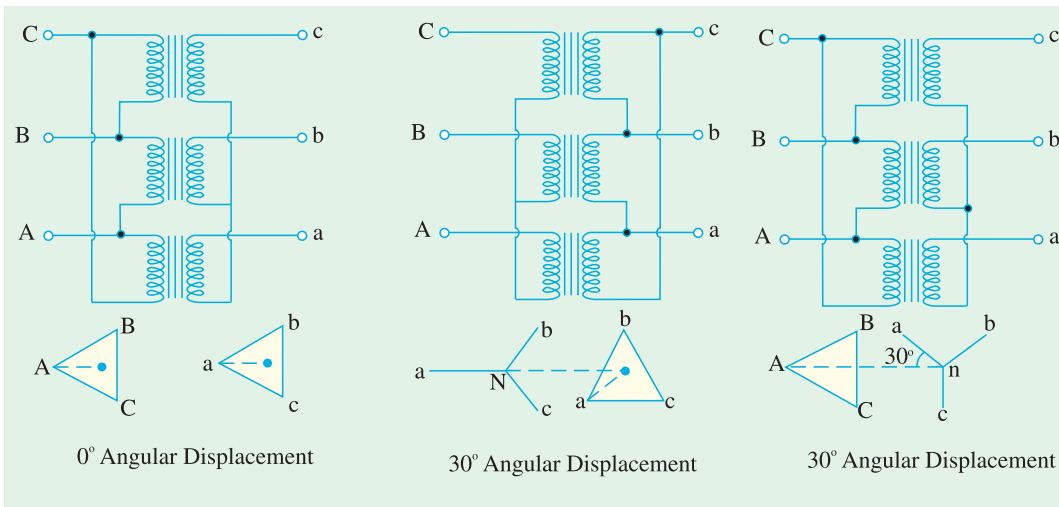

Fig. 33.5

Fig. 33.6

Fig. 33.7

### 33.5. Wye/Delta or Y/Δ Connection

The main use of this connection is at the substation end of the transmission line where the voltage is to be stepped down. The primary winding is Y-connected with grounded neutral as shown in Fig. 33.6. The ratio between the secondary and primary line voltage is  $1/\sqrt{3}$  times the transformation ratio of each transformer. There is a  $30^\circ$  shift between the primary and secondary line voltages which means that a Y-Δ transformer bank cannot be paralleled with either a Y-Y or a Δ-Δ bank. Also, third harmonic currents flows in the Δ to provide a sinusoidal flux.

### 33.6. Delta/Wye or Δ/Y Connection

This connection is generally employed where it is necessary to step up the voltage as for example, at the beginning of high tension transmission system. The connection is shown in Fig. 33.7. The neutral of the secondary is grounded for providing 3-phase 4-wire service. In recent years, this connection has gained considerable popularity because it can be used to serve both the 3-phase power equipment and single-phase lighting circuits.

This connection is not open to the objection of a floating neutral and voltage distortion because the existence of a Δ-connection allows a path for the third-harmonic currents. It would be observed that the primary and secondary line voltages and line currents are out of phase with each other by  $30^\circ$ . Because of this  $30^\circ$  shift, it is impossible to parallel such a bank with a Δ-Δ or Y-Y bank of transformers even though the voltage ratios are correctly adjusted. The ratio of secondary to primary voltage is  $\sqrt{3}$  times the transformation ratio of each transformer.

**Example 33.1.** A 3-phase, 50-Hz transformer has a delta-connected primary and star-connected secondary, the line voltages being 22,000 V and 400 V respectively. The secondary has a star-connected balanced load at 0.8 power factor lagging. The line current on the primary side is 5 A. Determine the current in each coil of the primary and in each secondary line. What is the output of the transformer in kW ?

**Solution.** It should be noted that in three-phase transformers, the *phase* transformation ratio is equal to the turn ratio but the terminal or line voltages depend upon the method of connection employed. The Δ/Y connection is shown in Fig. 33.8.

Fig. 33.8

Phase voltage on primary side = 22,000 V  
 Phase voltage on secondary side =  $400/\sqrt{3}$   
 $\therefore K = 400/22,000 \times \sqrt{3} = 1/55\sqrt{3}$   
 Primary phase current =  $5/\sqrt{3}$  A  
 Secondary phase current =  $\frac{5}{\sqrt{3}} \div \frac{1}{55\sqrt{3}} = 275$  A  
 Secondary line current = **275 A**  
 $\therefore$  Output =  $\sqrt{3}V_L I_L \cos \phi = \sqrt{3} \times 400 \times 275 \times 0.8 = \mathbf{15.24 \text{ kW}}$ .

**Example 33.2.** A 500-kVA, 3-phase, 50-Hz transformer has a voltage ratio (line voltages) of 33/11-kV and is delta/star connected. The resistances per phase are : high voltage 35  $\Omega$ , low voltage 0.876  $\Omega$  and the iron loss is 3050 W. Calculate the value of efficiency at full-load and one-half of full-load respectively (a) at unity p.f. and (b) 0.8 p.f. **(Electrical Machinery, Madras Univ. 1985)**

**Solution.** Transformation ratio  $K = \frac{11,000}{\sqrt{3} \times 33,000} = \frac{1}{3\sqrt{3}}$

Per phase  $R_{02} = 0.876 + (1/3\sqrt{3})^2 \times 35 = 2.172 \Omega$

Secondary phase current =  $\frac{500,000}{\sqrt{3} \times 11,000} = \frac{500}{11\sqrt{3}}$  A

**Full-load condition**

Full load total Cu loss =  $3 \times (500/11\sqrt{3})^2 \times 2.172 = 4,490$  W; Iron loss = 3,050 W

Total full-load losses = 4,490 + 3,050 = 7,540 W; Output at unity p.f. = 500 kW

$\therefore$  F.L. efficiency =  $500,000/507,540 = 0.9854$  or **98.54%**; Output at 0.8 p.f. = 400 kW

$\therefore$  Efficiency =  $400,000/407,540 = 0.982$  or **98.2%**

**Half-load condition**

Output at unity p.f. = 250 kW  
 Cu losses =  $(1/2)^2 \times 4,490 = \mathbf{1,222 \text{ W}}$

Total losses = 3,050 + 1,122 = 4,172 W

Three-phase transformer

$$\therefore \eta = 250,000/254,172 = 0.9835 = \mathbf{98.35\%}$$

Output at 0.8 p.f. = 200 kW  $\therefore \eta = 200,000/204,172 = \mathbf{0.98}$  or **98%**

**Example 33.3.** A 3-phase, 6,600/415-V, 2,000-kVA transformer has a per unit resistance of 0.02 and a per unit leakage reactance of 0.1. Calculate the Cu loss and regulation at full-load 0.8 p.f. lag. **(Electrical Machines-I, Bombay Univ. 1987)**

**Solution.** As seen from Art. 27 – 16, %  $R = \% \text{ Cu loss} = \frac{\text{Cu loss}}{VA} \times 100$

Now, %  $R = 0.02 \times 100 = 2\%$   $\therefore 2 = \frac{\text{Cu loss}}{2,000} \times 100 \therefore \text{Cu loss} = \mathbf{40 \text{ kW}}$

Now, percentage leakage reactance =  $0.1 \times 100 = 10\%$

$$\text{Regn.} = v_r \cos \phi + v_x \sin \phi = 2 \times 0.8 + 10 \times 0.6 = \mathbf{7.6\%}$$

**Example 33.4.** A 120-kVA, 6,000/400-V, Y/Y 3-ph, 50-Hz transformer has an iron loss of 1,600 W. The maximum efficiency occurs at 3/4 full load.

Find the efficiencies of the transformer at

- (i) full-load and 0.8 power factor (ii) half-load and unity power factor  
 (iii) the maximum efficiency. **(Elect. Technology Utkal Univ. 1987)**

**Solution.** Since maximum efficiency occurs at 3/4 full-load, Cu loss at 3/4 full-load equals iron loss of 1,600 W.

Cu loss at 3/4 F.L. = 1,600 W; Cu loss at F.L. =  $1,600 \times (4/3)^2 = 2,845 \text{ W}$

(i) F.L. output at 0.8 p.f. =  $120 \times 0.8 = 96 \text{ kW} = 96,000 \text{ W}$

Total loss =  $1,600 + 2,845 = 4,445 \text{ W}$

$$\therefore \eta = \frac{96,000}{100,445} \times 100 = \mathbf{95.57\%}$$

(ii) Cu loss at 1/2 full-load =  $(1/2)^2 \times 2,845 = 710 \text{ W}$

Total loss =  $710 + 1,600 = 2,310 \text{ W}$

Output at 1/2 F.L. and u.p.f. is =  $60 \text{ kW} = 60,000 \text{ W}$ ;  $\eta = \frac{60,000}{62,310} \times 100 = \mathbf{96.57\%}$

(iii) Maximum efficiency occurs at 3/4 full-load when iron loss equals Cu loss.

Total loss =  $2 \times 1,600 = 3,200 \text{ W}$

Output at u.p.f. =  $(3/4) \times 120 = 90 \text{ kW} = 90,000 \text{ W}$

Input =  $90,000 + 3,200 = 93,200 \text{ W} \therefore \eta = \frac{90,000}{93,200} \times 100 = \mathbf{96.57\%}$

**Example 33.5.** A 3-phase transformer, ratio 33/6.6-kV,  $\Delta/Y$ , 2-MVA has a primary resistance of 8  $\Omega$  per phase and a secondary resistance of 0.08 ohm per phase. The percentage impedance is 7%. Calculate the secondary voltage with rated primary voltage and hence the regulation for full-load 0.75 p.f. lagging conditions. **(Elect. Machine-I, Nagpur, Univ. 1993)**

**Solution.** F.L. secondary current =  $\frac{2 \times 10^6}{\sqrt{3} \times 6.6 \times 10^3} = 175 \text{ A}$

$$K = 6.6 / \sqrt{3} \times 33 = 1/8.65; R_{02} = 0.08 + 8/8.65^2 = 0.1867 \Omega \text{ per phase}$$

Now, secondary impedance drop per phase =  $\frac{7}{100} \times \frac{6,600}{\sqrt{3}} = 266.7 \text{ V}$

$$\therefore Z_{02} = 266.7/175 = 1.523 \Omega \text{ per phase}$$

$$X_{02} = \sqrt{Z_{02}^2 - R_{02}^2} = \sqrt{1.523^2 - 0.1867^2} = 1.51 \Omega / \text{phase}$$

Drop per phase =  $I_2 (R_{02} \cos \phi + X_{02} \sin \phi) = 175 (0.1867 \times 0.75 + 1.51 \times 0.66) = 200 \text{ V}$

Secondary voltage/phase =  $6,600 / \sqrt{3} = 3,810 \text{ V} \quad \therefore V_2 = 3,810 - 200 = 3,610 \text{ V}$

$\therefore$  Secondary line voltage =  $3,610 \times \sqrt{3} = \mathbf{6,250 \text{ V}}$

%regn. =  $200 \times 100 / 3,810 = \mathbf{5.23 \%}$

**Example 33.6.** A 100-kVA, 3-phase, 50-Hz 3,300/400 V transformer is  $\Delta$ -connected on the h.v. side and Y-connected on the l.v. side. The resistance of the h.v. winding is 3.5  $\Omega$  per phase and that of the l.v. winding 0.02  $\Omega$  per phase. Calculate the iron losses of the transformer at normal voltage and frequency if its full-load efficiency be 95.8% at 0.8 p.f. (lag).

(A.C. Machines-I, Jadavpur Univ. 1989)

**Solution.** F.L. output =  $100 \times 0.8 = 80 \text{ kW}$ ; Input =  $80 / 0.958 = 83.5 \text{ kW}$

Total loss = Input – Output =  $83.5 - 80 = 3.5 \text{ kW}$

Let us find full-load Cu losses for which purpose, we would first calculate  $R_{02}$ .

$$K = \frac{\text{secondary voltage/phase}}{\text{primary voltage/phase}} = \frac{400 / \sqrt{3}}{3,300} = \frac{4}{33\sqrt{3}}$$

$$R_{02} = R_2 + K^2 R_1 = 0.02 + (4 / \sqrt{3} \times 33)^2 \times 3.5 = 0.037 \Omega$$

Full-load secondary phase current is  $I_2 = 100,000 / \sqrt{3} \times 400 = 144.1 \text{ A}$

Total Cu loss =  $3 I_2^2 R_{02} = 3 \times 144.1^2 \times 0.037 = 2,305 \text{ W}$

Iron loss = Total loss – F.L. Cu loss =  $3,500 - 2,305 = \mathbf{1,195 \text{ W}}$

**Example 33.7.** A 5,000-kVA, 3-phase transformer, 6.6/33-kV,  $\Delta/Y$ , has a no-load loss of 15 kW and a full-load loss of 50 kW. The impedance drop at full-load is 7%. Calculate the primary voltage when a load of 3,200 kW at 0.8 p.f. is delivered at 33 kV.

**Solution.** Full-load  $I_2 = 5 \times 10^6 / \sqrt{3} \times 33,000 = 87.5 \text{ A}$

Impedance drop/phase = 7% of  $(33 / \sqrt{3}) = 7\%$  of 19 kV = 1,330 V

$\therefore Z_{02} = 1,330 / 87.5 = 15.3 \Omega / \text{phase}$ ; F.L. Cu loss =  $50 - 15 = 35 \text{ kW}$

$\therefore 3 I_2 R_{02} = 35,000$ ;  $R_{02} = 35,000 / 3 \times 8.75^2 = 1.53 \Omega / \text{phase}$

$\therefore X_{02} = \sqrt{15.3^2 - 1.53^2} = \mathbf{15.23 \Omega}$

**When load is 3,200 kW at 0.8 p.f.**

$I_2 = 3,200 / \sqrt{3} \times 33 \times 0.8 = 70 \text{ A}$ ; drop =  $70 (1.53 \times 0.8 + 15.23 \times 0.6) = 725 \text{ V/phase}$

$\therefore$  % regn. =  $\frac{725 \times 100}{19,000} = 3.8 \%$

Primary voltage will have to be increased by 3.8%.

$\therefore$  Primary voltage =  $6.6 + 3.8\%$  of 6.6 = 6.85 kV =  $\mathbf{6,850 \text{ V}}$

**Example 33.8.** A 3-phase transformer has its primary connected in  $\Delta$  and its secondary in Y. It has an equivalent resistance of 1% and an equivalent reactance of 6%. The primary applied voltage is 6,600 V. What must be the ratio of transformation in order that it will deliver 4,800 V at full-load current and 0.8 power factor (lag) ?

(Elect. Technology-II, Magadh Univ. 1991)

**Solution.** Percentage regulation

$$= v_r \cos \phi + v_x \sin \phi$$

$$= 1 \times 0.8 + 6 \times 0.6 = 4.4\%$$

Induced secondary e.m.f. (line value)

$$= 4,800 + 4.4\% \text{ of } 4,800 = 5,010 \text{ V, as in Fig. 33.9.}$$

Secondary phase voltage

$$= 5,010 / \sqrt{3} = 2,890 \text{ V}$$

Transformation ratio

$$K = 2,890 / 6,600 = \mathbf{0.437.}$$

Fig. 33.9

**Example 33.9.** A 2000-kVA, 6,600/400-V, 3-phase transformer is delta-connected on the high voltage side and star-connected on the low-voltage side. Determine its % resistance drops, % efficiency and % regulation on full load 0.8 p.f. leading given the following data :  
 S.C. test ; H.V. data : 400 V, 175 A and 17 kW  
 O.C. test; L.V. data : 400 V, 150 A and 15 kW **(Basic Elect., Machines Nagpur Univ. 1993)**

**Solution.** From S.C. test data, we have

Primary voltage/phase = 400 V; Primary current/phase =  $175 / \sqrt{3} = 100 \text{ A}$

$$\therefore Z_{01} = \frac{400}{101} = 3.96 \Omega$$

$$I_1^2 R_{01} = \frac{17000}{3} \text{ or } R_{01} = 0.555 \Omega; X_{01} = \sqrt{3.96^2 - 0.555^2} = 3.92 \Omega$$

$$\% R = \frac{I_1 R_{01}}{V_1} \times 100 = \frac{101 \times 0.555}{6,600} \times 100 = \mathbf{0.849}$$

$$\% X = \frac{I_1 X_{01}}{V_1} \times 100 = \frac{101 \times 3.92}{6,600} \times 100 = \mathbf{6}$$

$$\% \text{ regn} = v_r \cos \phi - v_x \sin \phi = 0.49 \times 0.8 - 6 \times 0.6 = -2.92\%$$

Full-load primary line current can be found from

$$\sqrt{3} \times 6,600 \times I_1 = 2000 \times 1,000; I_1 = 175 \text{ A}$$

It shows that S.C. test has been carried out under full-load conditions.

Total losses = 17 + 15 = 32 kW; F.L. output =  $2,000 \times 0.8 = 1600 \text{ kW}$

$$\eta = 1,600 / 1,632 = 0.98 \text{ or } \mathbf{98\%}$$

**Example 33.10.** A 3-ph, delta/star connected 11,000/440 V, 50 Hz transformer takes a line current of 5 amp, when secondary Load of 0.8 Lagging p.f. is connected. Determine each coil-current and output of transformer. **(Amravati Univ. 1999)**

**Solution.** Due to delta/star connections the voltage ratings of the two sides on per phase basis are :

Primary coil rating = 11,000 V, Secondary coil rating =  $\frac{440}{\sqrt{3}} = 254 \text{ volts}$

Primary coil-current =  $5 / \sqrt{3} = 2.887 \text{ amp}$

Each coil is delivering equal volt. amps.

Since three phase volt – amps =  $3 \times 11,000 \times 5 / \sqrt{3}$   
 = 95266

Volts amps/phase = 31755

This corresponds to the secondary coil-current of  $I_2$ , given by

$$I_2 = \frac{31755}{254} = 125 \text{ amp. This is shown in Fig. 33.10.}$$

Total Output of transformer, in kVA = 31,755

Since, the p.f. given is 0.8 lagging.

The total output power in kW =  $31,755 \times 0.80 = 25.4 \text{ kW}$

Fig. 33.10. Transformer coil currents

**Example 33.11.** A load of 1000 kVA at 0.866 p.f. lagging is supplied by two 3 phase transformers of 800 kVA capacity operating in parallel. Ratio of transformation is same : 6600/400 V, delta/star. If the equivalent impedances referred to secondary are  $(0.005 + j.015)$  ohm and  $(0.012 + j 0.030)$  ohm per phase respectively. Calculate load and power factor of each transformer.

(Amravati Univ. 1999)

**Solution.** Total load = 1000 kVA  
 $\cos \phi = 0.866$  Lag,  $\phi = 30^\circ$  lag  
 Total power output = 866 kW  
 Secondary current with star connection,

$$I_2 = \frac{1000}{\sqrt{3} \times 440} \times 1000 = 1312.2 \text{ amp}$$

If the two transformers are identified as A and B, with their parameters with subscripts of a and b, we have :

$$\begin{aligned} \dot{Z}_a &= 0.005 + j0.015 = 0.0158 \angle 71.56^\circ \text{ ohm} \\ \dot{Z}_b &= 0.012 + j0.030 = 0.0323 \angle 68.2^\circ \text{ ohm} \\ \dot{Z}_a + \dot{Z}_b &= 0.017 + j0.045 = 0.0481 \angle 69.3^\circ \text{ ohm} \\ \dot{i}_{2a} &= \text{secondary current of transformer A} \\ \dot{i}_{2b} &= \text{secondary current of transformer B} \\ \dot{i}_{2a} &= \frac{\dot{Z}_b}{\dot{Z}_b + \dot{Z}_a} \times \dot{I}_2 = \frac{0.0323 \angle 68.2^\circ}{0.0481 \angle 69.3^\circ} \times 1312 \angle -30^\circ \\ &= 88.1 \angle -31.1^\circ \\ \dot{i}_{2b} &= \frac{\dot{Z}_a}{\dot{Z}_a + \dot{Z}_b} \times \dot{I}_2 = \frac{0.0158 \angle 71.56^\circ}{0.0481 \angle 69.3^\circ} \times 1312 \angle -30^\circ \\ &= 43.1 \angle -27.74^\circ \end{aligned}$$

**For Transformer A**

Load =  $3 \times 254 \times 881 \times 10^{-3} = 671.3 \text{ kVA}$

Power factor =  $\cos 31.1^\circ \text{ lag} = 0.856 \text{ lag}$

**For Transformer B**

Load =  $3 \times 254 \times 431 \times 10^{-3} = 328.4 \text{ kVA}$

Power factor =  $\cos 23.74^\circ \text{ lag} = 0.885 \text{ lag}$

**Check :** Total kW gives a check.

1000 kVA at 0.866 lag means 866 kW.

Output, in kW, of transformer A =  $671.3 \times 0.856 = 574.6 \text{ kW}$

Output in kW of transformer B =  $328.4 \times 0.885 = 290.6 \text{ kW}$

Sum of these two outputs =  $574.6 + 290.6 = 865.2 \text{ kW}$

**Note.** Total kVAR also gives a check.

Depending on leading or lagging p.f., appropriate sign (+ ve or - ve) must be assigned to the kVAR-term.

**Tutorial Problem No. 33.1**

1. A 3-phase, star-connected alternator generates 6,360 V per phase and supplies 500 kW at a p.f. 0.9 lagging to a load through a step-down transformer of turns 40 : 1. The transformer is delta connected on the primary side and star-connected on the secondary side. Calculate the value of the line volts at the load. Calculate also the currents in (a) alternator windings (b) transformer primary windings (c) transformen secondary windings. **[476 V (a) 29.1 A (b) 16.8 A (c) 672 A]**

2. A 11,000/6,600 V, 3- $\phi$ , transformer has a star-connected primary and a delta-connected secondary. It supplies a 6.6 kV motor having a star-connected stator, developing 969.8 kW at a power factor of 0.9 lagging and an efficiency of 92 per cent. Calculate (i) motor line and phase currents (ii) transformer secondary current and (iii) transformer primary current.

**[(a) Motor ;  $I_L = I_{ph} = 126.3 \text{ A}$  (b) phase current 73 A (c) 75.8 A]**

**33.7. Open-Delta or V – V connection**

If one of the transformers of a  $\Delta - \Delta$  is removed and 3-phase supply is connected to the primaries as shown in Fig. 33.11, then three equal 3-phase voltages will be available at the secondary terminals on no-load. This method of transforming 3-phase power by means of only two transformers is called the open -  $\Delta$  or V – V connection.

It is employed :

1. when the three-phase load is too small to warrant the installation of full three-phase transformer bank.
2. when one of the transformers in a  $\Delta - \Delta$  bank is disabled, so that service is continued although at reduced capacity, till the faulty transformer is repaired or a new one is substituted.
3. when it is anticipated that in future the load will increase necessitating the closing of open delta.

One important point to note is that the total load that can be carried by a V – V bank is *not* two-third of the capacity of a  $\Delta - \Delta$  bank but it is only 57.7% of it. That is a reduction of 15% (strictly, 15.5%) from its normal rating. Suppose there is  $\Delta - \Delta$  bank of three 10-kVA transformers. When one transformer is removed, then it runs in V – V. The total rating of the two transformers is 20 kVA. But the capacity of the V – V bank is not the sum of the transformer kVA ratings but only 0.866 of it i.e.  $20 \times 0.866 = 17.32$  (or  $30 \times 0.57 = 17.3 \text{ kVA}$ ). The fact that the ratio of V-capacity to  $\Delta$ -capacity is  $1/\sqrt{3} = 57.7\%$  (or nearly 58%) instead of  $66\frac{2}{3}\%$  per cent can be proved as follows :

**Fig. 33.11**

As seen from Fig. 33.12 (a)

$$\Delta - \Delta \text{ capacity} = \sqrt{3} \cdot V_L \cdot I_L = \sqrt{3} \cdot V_L (\sqrt{3} \cdot I_S) = 3 V_L I_S$$

In Fig. 33.12 (b), it is obvious that when  $\Delta - \Delta$  bank becomes  $V - V$  bank, the secondary line current  $I_L$  becomes equal to the secondary phase current  $I_S$

$$\therefore V - V \text{ capacity} = \sqrt{3} \cdot V_L I_L = \sqrt{3} V_L \cdot I_S$$

$$\therefore \frac{V - V \text{ capacity}}{\Delta - \Delta \text{ capacity}} = \frac{\sqrt{3} \cdot V_L I_S}{3 V_L I_S} = \frac{1}{\sqrt{3}} = 0.577 \text{ or } 58 \text{ per cent}$$

It means that the 3-phase load which can be carried **without exceeding the ratings** of the transformer is 57.7 per cent of the original load rather than the expected 66.7%.

Fig. 33.12

It is obvious from above that when one transformer is removed from a  $\Delta - \Delta$  bank.

1. the bank capacity is reduced from 30 kVA to  $30 \times 0.577 = 17.3$  kVA and not to 20 kVA as might be thought off-hand.
2. only 86.6% of the rated capacity of the two remaining transformers is available (*i.e.*  $20 \times 0.866 = 17.3$  kVA). In other words, ratio of *operating* capacity to *available* capacity of an open- $\Delta$  is 0.866. This factor of 0.866 is sometimes called the **utility factor**.
3. each transformer will supply 57.7% of load and not 50% when operating in  $V - V$  (Ex. 33.13).

However, it is worth noting that if three transformers in a  $\Delta - \Delta$  bank are delivering their *rated load*\* and one transformer is removed, the overload on *each* of the two remaining transformers is 73.2% because

$$\frac{\text{total load in } V - V}{VA/\text{transformer}} = \frac{\sqrt{3} \cdot V_L I_S}{V_L I_S} = \sqrt{3} = 1.732$$

This over-load may be carried temporarily but some provision must be made to reduce the load if overheating and consequent breakdown of the remaining two transformers is to be avoided.

The disadvantages of this connection are :

1. The average power factor at which the  $V$ -bank operates is less than that of the load. **This power factor is actually 86.6% of the balanced load power factor**. Another significant point to note is that, except for a balanced unity power factor load, the two transformers in the  $V - V$  bank operate at different power factors (Art. 33.8).
2. Secondary terminal voltages tend to become unbalanced to a great extent when the load is increased, this happens even when the load is perfectly balanced.

It may, however, be noted that if two transformers are operating in  $V - V$  and loaded to rated capacity (in the above example, to 17.3 kVA), the addition of a third transformer increases the total capacity by  $\sqrt{3}$  or 173.2% (*i.e.* to 30 kVA). It means that for an increase in cost of 50% for the third transformer, the increase in capacity is 73.2% when converting from a  $V - V$  system to a  $\Delta - \Delta$  system.

\* In Ex. 33.13, the three transformers are not supplying their rated load of  $20 \times 3 = 60$  kVA but only 40 kVA.

### 33.8. Power Supplied by V – V Bank

When a V–V bank of two transformers supplies a balanced 3-phase load of power factor  $\cos \phi$ , then one transformer operates at a p.f. of  $\cos (30^\circ - \phi)$  and the other at  $\cos (30^\circ + \phi)$ . Consequently, the two transformers will not have the same voltage regulation.

$$\therefore P_1 = \text{kVA} \cos (30^\circ - \phi) \text{ and } P_2 = \text{kVA} \cos (30^\circ + \phi)$$

**(i) When  $\phi = 0$  i.e. load p.f. = 1**

Each transformer will have a p.f. =  $\cos 30^\circ = 0.866$

**(ii) When  $\phi = 30^\circ$  i.e. load p.f. = 0.866.**

In this case, one transformer has a p.f. of  $\cos (30^\circ - 30^\circ) = 1$  and the other of  $\cos (30^\circ + 30^\circ) = 0.866$ .

**(iii) When  $\phi = 60^\circ$  i.e. load p.f. = 0.5**

In this case, one transformer will have a p.f. =  $\cos (30^\circ - 60^\circ) = \cos (-30^\circ) = 0.866$  and the other of  $\cos (30^\circ + 60^\circ) = 0$ . It means that one of the transformers will not supply any load whereas the other having a p.f. = 0.866 will supply the entire load.

**Example 33.12.** What should be the kVA rating of each transformer in a V–V bank when the 3-phase balanced load is 40 kVA? If a third similar transformer is connected for operation, what is the rated capacity? What percentage increase in rating is affected in this way?

**Solution.** As pointed out earlier, the kVA rating of each transformer has to be 15% greater.

$$\therefore \text{kVA/transformer} = (40/2) \times 1.15 = 23$$

$$\Delta - \Delta \text{ bank rating} = 23 \times 3 = 69; \text{ Increase} = [(69 - 40)/40] \times 100 = 72.5\%$$

**Example 33.13.** A  $\Delta - \Delta$  bank consisting of three 20-kVA, 2300/230-V transformers supplies a load of 40 kVA. If one transformer is removed, find for the resulting V–V connection

- kVA load carried by each transformer
- per cent of rated load carried by each transformer
- total kVA rating of the V–V bank
- ratio of the V–V bank to  $\Delta - \Delta$  bank transformer ratings.
- per cent increase in load on each transformer when bank is converted into V–V bank.

**Solution. (i)** As explained earlier in Art. 33.7,  $\frac{\text{total kVA load in V – V bank}}{\text{VA/transformer}} = \sqrt{3}$

$$\therefore \text{kVA load supplied by each of the two transformers} = 40 / \sqrt{3} = 23.1 \text{ kVA}$$

Obviously, each transformer in V–V bank does not carry 50% of the original load but 57.7%.

$$\text{(ii) per cent of rated load} = \frac{\text{kVA load/transformer}}{\text{kVA rating/transformer}} = \frac{23.1}{20} = 115.5\%$$

carried by each transformer.

Obviously, in this case, each transformer is overloaded to the extent of 15.5 per cent.\*

$$\text{(iii) kVA rating of the V – V bank} = (2 \times 20) \times 0.866 = 34.64 \text{ kVA}$$

$$\text{(iv) } \frac{\text{V – V rating}}{\Delta - \Delta \text{ rating}} = \frac{34.64}{60} = 0.577 \text{ or } 57.7\%$$

\* Overloading becomes 73.2% only when full rated load is supplied by the  $\Delta - \Delta$  bank (i.e.  $3 \times 20 = 60$  kVA in this case) before it becomes V–V bank.

As seen, the rating is reduced to 57.7% of the original rating.

(v) Load supplied by each transformer in  $\Delta - \Delta$  bank =  $40/3 = 13.33$  kVA

$\therefore$  Percentage increase in load supplied by each transformer

$$= \frac{\text{kVA load/transformer in } V - V \text{ bank}}{\text{kVA load/transformer in } \Delta - \Delta \text{ bank}} = \frac{23.1}{13.3} = 1.732 = \mathbf{173.2\%}$$

It is obvious that each transformer in the  $\Delta - \Delta$  bank supplying 40 kVA was running underloaded (13.33 vs 20 kVA) but runs overloaded (23.1 vs 20 kVA) in  $V - V$  connection.

**Example 33.14.** A balanced 3-phase load of 150 kW at 1000 V, 0.866 lagging power factor is supplied from 2000 V, 3-phase mains through single-phase transformers (assumed to be ideal) connected in (i) delta-delta (ii) Vee-Vee. Find the current in the windings of each transformer and the power factor at which they operate in each case. Explain your calculations with circuit and vector diagrams.

**Solution. (i) Delta-Delta Connection**

$$\sqrt{3} V_L I_L \cos \phi = 150,000$$

$$\sqrt{3} \times 1000 \times I_L \times 0.866 = 150,000 \therefore I_L = 100 \text{ A}$$

$\therefore$  Secondary line current = 100 A; secondary phase current =  $100/\sqrt{3} = \mathbf{57.7 \text{ A}}$

Transformation ratio =  $1000/2000 = 1/2$

$\therefore$  Primary phase current =  $57.7/2 = \mathbf{28.85 \text{ A}}$

**(ii) Vee-Vee Connection**

Let  $I$  be the secondary line current which is also the phase current in  $V - V$  connection. Then

$$\sqrt{3} \times 1000 \times I \times 0.866 = 150,000 \therefore I = 100 \text{ A}$$

$\therefore$  Secondary phase current =  $\mathbf{100 \text{ A}}$ ; primary phase current =  $100 \times 1/2 = \mathbf{50 \text{ A}}$

Transformer power factor = 86.6 per cent of 0.866 =  $\mathbf{0.75 \text{ (lag)}}$ .

**Example 33.15.** (a) Two identical 1-phase transformers are connected in open-delta across 3-phase mains and deliver a balanced load of 3000 kW at 11 kV and 0.8 p.f. lagging. Calculate the line and phase currents and the power factors at which the two transformers are working.

(b) If one more identical unit is added and the open delta is converted to closed delta, calculate the additional load of the same power factor that can now be supplied for the same temperature rise. Also calculate the phase and line currents. **(Elect. Machinery-I, Madras Univ. 1987)**

**Solution. (a)** If  $I$  is the line current, then

$$\sqrt{3} \times 11,000 \times I \times 0.8 = 3,000,000 \qquad \mathbf{I = 197 \text{ A}}$$

Since, this also represents the phase current,

$\therefore$  Secondary phase current =  $\mathbf{197 \text{ A}}$ ; Transformer p.f. = 86.6 per cent of 0.8 =  $\mathbf{0.693}$

**(b)** Additional load = 72.5 per cent of 3000 =  $\mathbf{2175 \text{ kW}}$

Total load =  $3000 + 2175 = 5175 \text{ kW}$

Now,  $\sqrt{3} \times V_L I_L \cos \phi = 5,175,000$  or  $\sqrt{3} \times 11,000 \times I_L \times 0.8 = 5,175,000$

$\therefore I_L = \mathbf{340 \text{ A}}$ ; phase current =  $340/\sqrt{3} = \mathbf{196 \text{ A}}$

**Example 33.16.** Two transformers connected in open delta supply a 400-kVA balanced load operating at 0.866 p.f. (lag). The load voltage is 440 V. What is the (a) kVA supplied by each transformer? (b) kW supplied by each transformer? **(Elect. Machines-I, Gwalior Univ. 1991)**

**Solution.** As stated in Art 33.7, the ratio of operating capacity to available capacity in an open- $\Delta$  is 0.866. Hence, kVA of each transformer is one-half of the total kVA load divided by 0.866.

(a) kVA of each transformer =  $\frac{(400/2)}{0.866} = 231 \text{ kVA}$

(b) As stated in Art 33.8, the two transformers have power factors of  $\cos(30^\circ - \phi)$  and  $\cos(30^\circ + \phi)$ .

$\therefore P_1 = \text{kVA} \cos(30^\circ - \phi)$  and  $P_2 = \text{kVA} \cos(30^\circ + \phi)$

Now, load p.f. =  $\cos \phi = 0.866$ ;  $\phi = \cos^{-1}(0.866) = 30^\circ$

$\therefore P_1 = 231 \times \cos 0^\circ = 231 \text{ kW}$ ;  $P_2 = 231 \times \cos 60^\circ = 115.5 \text{ kW}$

Obviously,  $P_1 + P_2$  must equal  $400 \times 0.86 = 346.5 \text{ kW}$

**Tutorial Problem No. 33.2**

1. Three 1100/110-V transformers connected delta-delta supply a lighting load of 100 kW. One of the transformers is damaged and removed for repairs. Find

- (a) What currents were flowing in each transformer when the three transformers were in service ?
- (b) What current flows in each transformer when the third is removed ? and
- (c) The output kVA of each transformer if the transformers connected in open  $\Delta$  supply the full-load with normal heating ?

[(a) primary = 30.3 A; secondary 303 A (b) primary =  $30.3 \sqrt{3} \text{ A}$ ; secondary =  $303\sqrt{3} \text{ A}$  (c) 33.33 kVA] (Elect. Machines-I, Gwalior Univ. Apr. 1977)

**33.9. Scott Connection or T - T Connection**

This is a connection by which 3-phase to 3-phase transformation is accomplished with the help of two transformers as shown in Fig. 33.13. Since it was first proposed by Charles F. Scott, it is frequently referred to as Scott connection. This connection can also be used for 3-phase to 2-phase transformation as explained in Art. 33.10.

One of the transformers has centre taps both on the primary and secondary windings (Fig. 33.13) and is known as the **main** transformer. It forms the horizontal member of the connection (Fig. 33.14).

The other transformer has a 0.866 tap and is known as **teaser** transformer. One end of both the primary and secondary of the teaser transformer is joined to the centre taps both primary and secondary of the main transformer respectively as shown in Fig. 33.14 (a). The other end A of the teaser primary and the two ends B and C of the main transformer primary are connected to the 3-phase supply.

Fig. 33.13

The voltage diagram is shown in Fig. 33.14 (a) where the 3-phase supply line voltage is assumed to be 100 V and a transformation ratio of unity. For understanding as to how 3-phase transformation results from this arrangement, it is desirable to think of the primary and secondary vector voltages as forming geometrical  $T_s'$  (from which this connection gets its name).

Fig. 33.14

In the primary voltage  $T$  of Fig. 33.14 (a),  $E_{DC}$  and  $E_{DB}$  are each 50 V and differ in phase by  $180^\circ$ , because both coils  $DB$  and  $DC$  are on the same magnetic circuit and are connected in opposition. Each side of the equilateral triangle represents 100 V. The voltage  $E_{DA}$  being the altitude of the equilateral triangle is equal to  $(\sqrt{3}/2) \times 100 = 86.6$  V and lags behind the voltage across the main by  $90^\circ$ . The same relation holds good in the secondary winding so that  $abc$  is a symmetrical 3-phase system.

With reference to the secondary voltage triangle of Fig. 33.14 (b), it should be noted that for a load of unity power factor, current  $I_{db}$  lags behind voltage  $E_{db}$  by  $30^\circ$  and  $I_{dc}$  leads  $E_{dc}$  by  $30^\circ$ . In other words, the teaser transformer and each half of the main transformer, all operate at different power factors.

Obviously, the full rating of the transformers is not being utilized. The teaser transformer operates at only 0.866 of its rated voltage and the main transformer coils operate at  $\cos 30^\circ = 0.866$  power factor, which is equivalent to the main transformer's coils working at 86.6 per cent of their kVA rating. Hence the capacity to rating ratio in a  $T-T$  connection is 86.6% — the same as in  $V-V$  connection if two identical units are used, although heating in the two cases is not the same.

If, however, both the teaser primary and secondary windings are designed for 86.6 volts only, then they will be operating at full rating, hence the combined rating of the arrangement would become  $(86.6 + 86.6)/(100 + 86.6) = 0.928$  of its total rating.\* In other words, ratio of kVA utilized to that available would be 0.928 which makes this connection more economical than open- $\Delta$  with its ratio of 0.866.

Fig. 33.15

\* Alternatively, VA capacity available is  $= V_L I_L + (0.866 V_L) I_L = 1.866 V_L I_L$  where  $I_L$  is the primary line current. Since 3-phase power is supplied, volt-amperes actually utilized  $= 1.732 V_L I_L$ . Hence, ratio of kVA actually utilized to those available is  $= 1.732 V_L I_L / 1.866 V_L I_L = 0.928$ .

Fig. 33.15 shows the secondary of the  $T-T$  connection with its different voltages based on a nominal voltage of 100 V. As seen, the neutral point  $n$  is one third way up from point  $d$ . If secondary voltage and current vector diagram is drawn for load power factor of unity, it will be found that

1. current in teaser transformer is in phase with the voltage.
2. in the main transformer, current leads the voltage by  $30^\circ$  across one half but lags the voltage by  $30^\circ$  across the other half as shown in Fig. 33.14 (b).

Hence, when a balanced load of p.f. =  $\cos \phi$ , is applied, the teaser current will lag or lead the voltage by  $\Phi$  while in the two halves of the main transformer, the angle between current and voltage will be  $(30^\circ - \Phi)$  and  $(30^\circ + \Phi)$ . The situation is similar to that existing in a  $V-V$  connection.

**Example 33.17.** Two  $T$ -connected transformers are used to supply a 440-V, 33-kVA balanced load from a balanced 3-phase supply of 3300 V. Calculate (a) voltage and current rating of each coil (b) kVA rating of the main and teaser transformer.

**Solution.** (a) Voltage across main primary is 3300 V whereas that across teaser primary is  $= 0.866 \times 3300 = 2858$  V.

The current is the same in the teaser and the main and equals the line current.

$$\therefore I_{LP} = 33,000 / \sqrt{3} \times 3300 = 5.77 \text{ A} \quad \text{---Fig. 33.16}$$

The secondary main voltage equals the line voltage of 440 V whereas teaser secondary voltage  $= 0.866 \times 440 = 381$  V.

The secondary line current,  $I_{LS} = I_{LP} / k = 5.77 / (440 / 3300) = 43.3$  A as shown in Fig. 33.16.

Fig. 33.16

- (b) Main kVA  $= 3300 \times 5.77 \times 10^{-3} = 19 \text{ kVA}$   
 Teaser kVA  $= 0.866 \times \text{main kVA} = 0.866 \times 19 = 16.4 \text{ kVA}$

### 33.10. Three-phase to Two-phase Conversion and vice-versa

This conversion is required to supply two-phase furnaces, to link two-phase circuit with 3-phase system and also to supply a 3-phase apparatus from a 2-phase supply source. For this purpose, Scott connection as shown in Fig. 33.17 is employed. This connection requires two transformers of different ratings although for interchangeability and provision of spares, both transformers may be identical but having suitable tapplings.

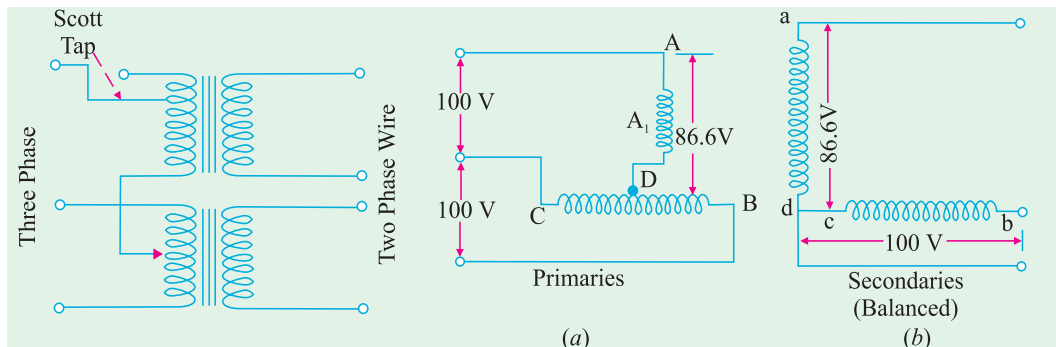

Fig. 33.17

Fig. 33.18

If, in the secondaries of Fig. 33.14 (b), points *c* and *d* are connected as shown in Fig. 33.18 (b), then a 2-phase, 3-wire system is obtained. The voltage  $E_{dc}$  is 86.6 V but  $E_{Cb} = 100$  V, hence the

Fig. 33.19

resulting 2-phase voltages will be unequal. However, as shown in Fig. 33.19 (a) if the 3-phase line is connected to point  $A_1$ , such that  $DA_1$  represents 86.6% of the teaser primary turns (which are the same as that of main primary), then this will increase the volts/turn in the ratio of 100 : 86.6, because now 86.6 volts are applied across 86.6 per cent of turns and not 100% turns. In other words, this will make volts/turn the same both in primary of the teaser and that of the main transformer. If the secondaries of both the transformers have the same number of turns, then secondary voltage will be equal in magnitude as shown, thus resulting in a symmetrical 2-phase, 3-wire system.

Consider the same connection drawn slightly differently as in Fig. 33.20. The primary of the main transformer having  $N_1$  turns is connected between terminals *CB* of a 3-phase supply. If supply line voltage is  $V$ , then obviously  $V_{AB} = V_{BC} = V_{CA} = V$  but voltage between *A* and *D* is  $V \times \sqrt{3}/2$ . As said

Fig. 33.20

Fig. 33.21

above, the number of turns between *A* and *D* should be also  $(\sqrt{3}/2) N_1$  for making volt/turn the same in both primaries. If so, then for secondaries having equal turns, the secondary terminal voltages will be equal in magnitude although in phase quadrature.

It is to be noted that point  $D$  is not the neutral point of the primary supply because its voltage with respect to any line is not  $V/\sqrt{3}$ . Let  $N$  be the neutral point. Its position can be determined as follows. Voltage of  $N$  with respect to  $A$  must be  $V/\sqrt{3}$  and since  $D$  to  $A$  voltage is  $V \times \sqrt{3}/2$ , hence  $N$  will be  $(\sqrt{3}V/2 - V/\sqrt{3}) = 0.288V$  or  $0.29V$  from  $D$ . Hence,  $N$  is above  $D$  by a number of turns equal to 29% of  $N_1$ . Since 0.288 is one-third of 0.866, hence  $N$  divides the teaser winding  $AD$  in the ratio 2 : 1.

Let the teaser secondary supply a current  $I_{2T}$  at unity power factor. If we neglect the magnetizing current  $I_0$ , then teaser primary current is  $I_{1T} = I_{2T} \times$  transformation ratio.

$\therefore I_{1T} = I_{2T} \times N_2/(\sqrt{3}N_1/2) = (2/\sqrt{3}) \times (N_2/N_1) \times I_{2T} = 1.15 (N_2/N_1) I_{2T} = 1.15 KI_{2T}$  where  $K = N_2/N_1 =$  transformation ratio of **main** transformer. The current is in phase with star voltage of the primary supply (Fig. 33.21).

The total current  $I_{1M}$  in each half of the primary of the **main** transformer consists of two parts :

(i) One part is that which is necessary to balance the main secondary current  $I_{2M}$ . Its value is

$$= I_{2M} \times \frac{N_2}{N_1} = KI_{2M}$$

(ii) The second part is equal to one-half of

the teaser primary current i.e.  $\frac{1}{2} I_{1T}$ . This is so because the main transformer primary forms a return path for the teaser primary current which divides itself into two halves at mid-point  $D$  in either direction. The value of each half is  $= I_{1T}/2 = 1.15 KI_{2T}/2 = 0.58 KI_{2T}$ .

Hence, the currents in the lines  $B$  and  $C$  are obtained vectorially as shown in Fig. 33.22. It should be noted that as the two halves of the teaser primary current flow in opposite directions from point  $D$ , they have no magnetic effect on the core and play no part at all in balancing the secondary ampere-turns of the main transformer.

The line currents thus have rectangular components of  $KI_{2M}$  and  $0.58 KI_{2T}$  and, as shown in Fig. 33.22, are in phase with the primary star voltages  $V_{NB}$  and  $V_{NC}$  and are equal to the teaser primary current. Hence, the three-phase side is balanced when the two-phase load of unity power factor is balanced.

Fig. 33.22

Fig. 33.23

Fig. 33.23 (a) illustrates the condition corresponding to a balanced two-phase load at a lagging power factor of 0.866. The construction is the same as in Fig. 33.22. It will be seen that the 3-phase side is again balanced. But under these conditions, the main transformer rating is 15% greater than that of the teaser, because its voltage is 15% greater although its current is the same.

Hence, **we conclude that if the load is balanced on one side, it would always be balanced on the other side.**

The conditions corresponding to an unbalanced two-phase load having different currents and power factors are shown in Fig. 33.23 (b). The geometrical construction is similar to those explained in Fig. 33.22 and 33.23 (a).

Summarizing the above we have :

1. Teaser transformer primary has  $\sqrt{3}/2$  times the turns of main primary. But volt/turn is the same. Their secondaries have the same turns which results in equal secondary terminal voltages.

2. If main primary has  $N_1$  turns and main secondary has  $N_2$  turns, then main transformation ratio is  $N_2/N_1$ . However, the transformation ratio of teaser is

$$N_2/(\sqrt{3}N_1/2) = 1.15 N_2/N_1 = 1.15 K$$

3. If the load is balanced on one side, it is balanced on the other side as well.

4. Under balanced load conditions, main transformer rating is 15% greater than that of the teaser.

5. The currents in either of the two halves of main primary are the vector sum of  $KI_{2M}$  and  $0.58 KI_{2T}$  (or  $\frac{1}{2} I_{1T}$ ).

**Example 33.18.** Two transformers are required for a Scott connection operating from a 440-V, 3-phase supply for supplying two single-phase furnaces at 200 V on the two-phase side. If the total output is 150 kVA, calculate the secondary to primary turn ratio and the winding currents of each transformer.

**Solution. Main Transformer**

Primary volts = 440 V ; secondary volts = 200 V  $\therefore \frac{N_2}{N_1} = \frac{200}{440} = \frac{1}{2.2}$

Secondary current =  $150,000/2 \times 200 = 375 \text{ A}$

$\therefore$  Primary current =  $375 \times 1/2.2 = 171 \text{ A}$

**Teaser Transformer**

Primary volts =  $(\sqrt{3}/2 \times 440) = 381 \text{ V}$  ; Secondary volts = 200 V

$$\frac{\text{secondary turns}}{\text{primary turns}} = \frac{200}{381} = \frac{1}{1.905} \text{ (also teaser ratio} = 1.15 \times 1/2.2 = 1/1.905)$$

**Example 33.19.** Two single-phase furnaces working at 100 V are connected to 3300-V, 3-phase mains through Scott-connected transformers. Calculate the current in each line of the 3-phase mains when the power taken by each furnace is 400-kW at a power factor of 0.8 lagging. Neglect losses in the transformers. **(Elect. Machines-III, South Gujarat Univ. 1988)**

**Solution.** Here  $K = 100/3,300 = 1/33$  (main transformer)

$$I_2 = \frac{400,000}{0.8 \times 100} = 5,000 \text{ A (Fig. 33.24); Here } I_{2T} = I_{2M} = I_2 = 5,000 \text{ A}$$

As the two-phase load is balanced, the 3-phase side is also balanced.

Primary phase currents are =  $1.15 KI_2 = 1.15 \times (1/33) \times 5,000 = 174.3 \text{ A}$

Since for a star-connection, phase current is equal to line current,

$\therefore$  Line current = **174.3 A**

**Note.** We have made use of the fact that since secondary load is balanced, primary load is also balanced. If necessary,  $I_{1M}$  can also be found.

$I_{1M}$  is the vector sum of (i)  $KI_{2M}$  and (ii)  $\frac{1}{2} I_{1T}$  or  $0.58 KI_{2T}$ .

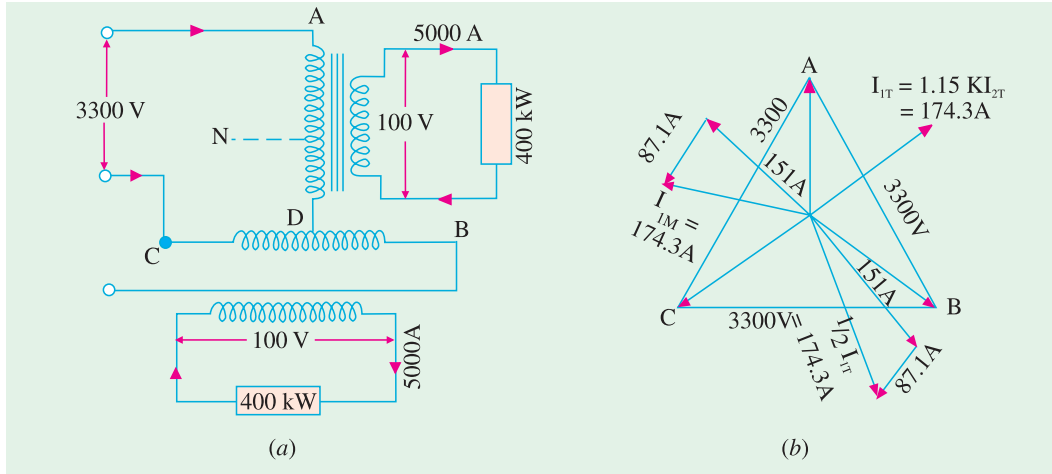

Fig. 33.24

Now,  $KI_{2M} = (1/33) \times 5,000 = 151 \text{ A}$  and  $0.58 KI_2 = \frac{1}{2} I_{1T} = 174.3/2 = 87.1 \text{ A}$

$$\therefore I_{1M} = \sqrt{151^2 + 87.1^2} = 174.3 \text{ A}$$

**Example 33.20.** In a Scott-connection, calculate the values of line currents on the 3-phase side if the loads on the 2-phase side are 300 kW and 450 kW both at 100 V and 0.707 p.f. (lag) and the 3-phase line voltage is 3,300 V. The 300-kW load is on the leading phase on the 2-phase side. Neglect transformer losses. **(Elect. Technology, Allahabad Univ. 1991)**

**Solution.** Connections are shown in Fig. 33.25 (a) and phasor diagram in Fig. 33.25 (b).

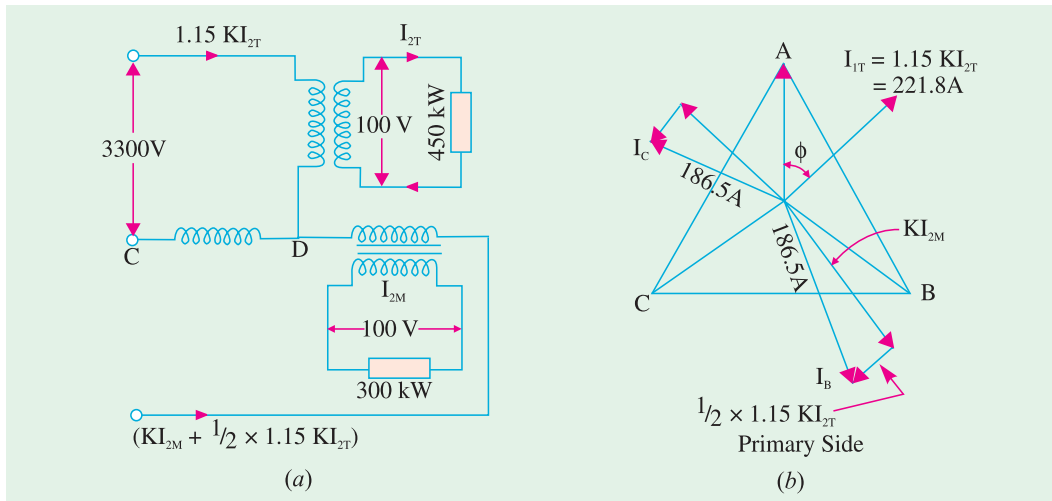

Fig. 33.25

Here,  $K = 100/3,300 = 1/33$

Teaser secondary current is  $I_{2T} = 450,000/100 \times 0.707 = 6360 \text{ A}$

Teaser primary current is  $I_{1T} = 1.15 KI_{2T} = 1.5 \times (1/33) \times 6360 = 221.8 \text{ A}$

As shown in Fig. 33.25 (b), main primary current  $I_{1M}$  has two rectangular components.

(i)  $KI_{2M}$  where  $I_{2M}$  is the secondary current of the main transformer and

(ii) Half of the teaser primary current  $\frac{1}{2} I_{1T} = \frac{1}{2} \times 1.15 KI_{2T} = 0.577 KI_{2T}$

Now  $KI_{2M} = \frac{1}{33} \times \frac{300,000}{100 \times 0.707} = 128.58 \text{ A}$ ; Also  $\frac{1}{2} I_{1T} = \frac{1}{2} \times 221.8 = 110.9 \text{ A}$

Main Primary current =  $\sqrt{128.58^2 + 110.9^2} = 169.79 \text{ A}$

Hence, the 3-phase line currents are **221.8 A** in one line and **169.79 A** in each of the other two.

**Example 33.21.** Two electric furnaces are supplied with 1-phase current at 80 V from a 3-phase, 11,000 V system by means of two single-phase Scott-connected transformers with similar secondary windings. When the load on one furnace is 500 kW (teaser secondary) and on the other 800 kW (secondary of main transformer) what current will flow in each of the 3-phase lines (a) at unity power factor and (b) at 0.5 power factor? Neglect phase displacement in and efficiency of, the transformers. **(Electrical Engineering, Madras Univ. 1987)**

**Solution.** The connections are shown in Fig. 33.26 and the phasor diagrams for unity and 0.5 p.f. are shown in Fig. 33.27 (a) and (b) respectively.

Fig. 33.26

Fig. 33.27

Here,

$$K = 80/11,000 = 2/275$$

(a) **Unity p.f.**

With reference to Fig. 33.27 (a), we have  $I_{2T} = 500,000/80 \times 1 = 6,250 \text{ A}$

Teaser primary current  $I_{1T} = 1.15 KI_{2T} = 1.15 \times (2/275) \times 6,250 = 52.5 \text{ A}$

For the main transformer primary

(i)  $KI_{2M} = \frac{2}{275} \times \frac{800,000}{80 \times 1} = 72.7 \text{ A}$  (ii)  $\frac{1}{2} \times I_{1T} = 52.5/2 = 26.25 \text{ A}$

Current in the primary of the main transformer is  $= \sqrt{72.7^2 + 26.25^2} = 77.1 \text{ A}$

Hence, one 3-phase line carries **52.5 A** whereas the other 2 carry **77.1 A** each [Fig. 33.27 (a)].

(b) **0.5 p.f.**

With reference to Fig. 33.27 (b) we have  $I_{2T} = 500,000/80 \times 0.5 = 12,500 \text{ A}$

Teaser primary current  $I_{1T} = 1.15 \times (2/275) \times 12,500 = 105 \text{ A}$

For the main transformer primary

(i) 
$$KI_{2M} = \frac{2}{275} \times \frac{800,000}{80 \times 0.5} = 145.4 \text{ A} \quad (ii) \quad \frac{1}{2} I_{1T} = 105/2 = 52.5 \text{ A}.$$

Current in the primary of the main transformer is  $= \sqrt{145.4^2 + 52.5^2} = 154.2 \text{ A}.$

Hence, one 3-phase line carries **105 A** and the other two carry **154.2 A** each.

**Note :** Part (b) need not be worked out in full because at 0.5 p.f., each component current and hence the resultant are doubled. Hence, in the second case, answers can be found by multiplying by a factor of 2 the line currents found in (a).

**Example 33.22.** Two furnaces are supplied with 1-phase current at 50 V from a 3-phase, 4.6 kV system by means of two 1-phase, Scott-connected transformers with similar secondary windings. When the load on the main transformer is 350 kW and that on the other transformer is 200 kW at 0.8 p.f. lagging, what will be the current in each 3-phase line ? Neglect phase displacement and losses in transformers. **(Electrical Machinery-II, Bangalore Univ. 1991)**

**Solution.** Connections and vector diagrams are shown in Fig. 33.28.

$$K = 50/4,600 = 1/92; \quad I_{2T} = 200,000/50 \times 0.8 = 5,000 \text{ A}$$

$$I_{1T} = 1.15 KI_{2T} = 1.1 \times (1/92) \times 5,000 = 62.5 \text{ A}$$

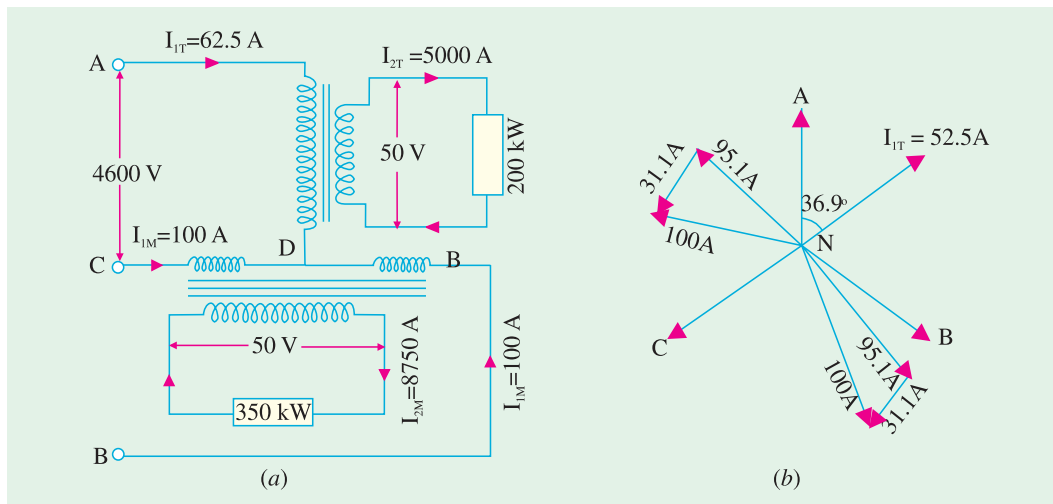

Fig. 33.28

As shown in Fig. 33.28 (b), main primary current  $I_{1M}$  has two rectangular components.

(i)  $KI_{2M}$  where  $I_{2M} = 350,000/50 \times 0.8 = 8,750 \text{ A} \therefore KI_{2M} = 8,750/92 = 95.1 \text{ A}$

(ii)  $(1/2) I_{1T} = 62.5/2 = 31.3 \text{ A} \quad \therefore I_{1M} = \sqrt{95.1^2 + 31.3^2} = 100 \text{ A}$

$\therefore$  Current in line A = **62.5 A**; Current in line B = **100 A**; Current in line C = **100 A**.

**Example 33.23.** Two single-phase Scott-connected transformers supply a 3-phase four-wire distribution system with 231 volts between lines and the neutral. The h.v. windings are connected to a two-phase system with a phase voltage of 6,600 V. Determine the number of turns in each section of the h.v. and l.v. winding and the position of the neutral point if the induced voltage per turn is 8 volts.

**Solution.** As the volt/turn is 8 and the h.v. side voltage is 6,600 V, the h.v. side turns are  $= 6,600/8 = 825$  on both transformers.

Now, voltage across points *B* and *C* of main winding  
 = line voltage =  $231 \times \sqrt{3} = 400 \text{ V}$

No. of turns on the l.v. side of the main transformer =  $400/8 = 50$

No. of turns on the l.v. side of teaser transformer =  $\sqrt{(3/2)} \times \text{mains turns}$   
 =  $\sqrt{3} \times 50 / 2 = 43$  (whole number)

The neutral point on the 3-phase side divides teaser turns in the ratio 1 : 2.

$\therefore$  Number of turns between *A* and *N* =  $(2/3) \times AD$   
 =  $(2/3) \times 43 = 29$

Hence, neutral point is located on the 29th turn from *A* downwards (Fig. 33.29).

Fig. 33.29

**Example 33.24.** A Scott-connected (2 to 3-phase) transformer links a 6,000 V, 2-phase system with a 440 V, 3-phase system. The frequency is 50 Hz, the gross core area is  $300 \text{ cm}^2$ , while the maximum flux density is to be about  $1.2 \text{ Wb/m}^2$ . Find the number of turns on each winding and the point to be tapped for the neutral wire on the 3-phase side. If the load is balanced on the one side of such a transformer, find whether it will also be balanced on the other side. (London Univ.)

**Solution.** Use the transformer voltage equation 1,

$$E = 4.44 f N \Phi_x \text{ volt}$$

$$\text{Gross core area} = 300 \text{ cm}^2$$

Assuming net iron = 0.9 of gross area, and considering the h.v. side, we have

$$6000 = 4.44 \times 50 \times N_1 \times 1.2 \quad (300 \times 0.9 \times 10^{-4})$$

$$N_1 = 834$$

Hence, h.v. sides of both transformers have 834 turns each.

$$\text{Now } K = 440/6000 = 11/150$$

$\therefore$  Turns on the l.v. side of main transformer

$$N_2 = 834 \times 11/150 = 61$$

$$\text{Turns on the l.v. side of teaser} = (\sqrt{3}/2) \times 61 = 53$$

$$\text{With reference to Fig. 33.30, number of turns in } AN = 53 \times 2/3 = 35$$

Fig. 33.30

**Example 33.25.** A 2-phase, 4-wire, 250 V system is supplied to a plant which has a 3-phase motor load of 30 kVA. Two Scott-connected transformers supply the 250 V motors. Calculate (a) voltage (b) kVA rating of each transformer. Draw the wiring connection diagram.

**Solution. (a)** Both the main and the teaser have the same voltage rating as the supply voltage i.e. 250 V. The current in the main and the teaser coils is the same as the supply current and is

$$= \frac{\text{Total kVA}}{2 \times \text{Line voltage}} = \frac{30,000}{2 \times 250} = 60 \text{ A arcsin } \theta$$

On the three-phase side, current is the same in all coils and is equal to the load line current  
 =  $30,000 / \sqrt{3} \times 250 = 69.3 \text{ A}$

Load voltage on main secondary = line voltage = 250 V

Load voltage on teaser secondary =  $0.866 \times 250 = 216.5 \text{ V}$

Hence, voltage rating of main transformer is **250/250** whereas that of teaser transformer is **250/216.5**.

The current rating of main transformer is **60/69.3** and it is the same for the teaser transformer.

(b) The volt-amp rating of the teaser primary as well as secondary is the same *i.e.*  $60 \times 250 \times 10^{-3} = 69.3 \times 216.5 \times 10^{-3} = \mathbf{15 \text{ kVA}}$

The main volt-ampere rating of secondary is  $= 250 \times 69.3 \times 10^{-3} = \mathbf{17.3 \text{ kVA}}$

Incidentally, if two identical transformers are used for providing inter-changeability, then both must be rated at 17.3 kVA. In that case, a total capacity of 34.6 kVA would be required to provide a 30 kVA load.

The wiring connections are shown in Fig. 33.31.

Fig. 33.31

### Tutorial Problem No. 33.3

1. A Scott-connected transformer is fed from a 6,600-V, 3-phase network and supplies two single-phase furnaces at 100 V. Calculate the line currents on the 3-phase side when the furnaces take 400 kW and 700 kW respectively at 0.8 power factor lagging. (Elect. Machines II, Indore Univ. 1977)

[With 400 kW on teaser, line currents are 87.2 A; 139 A; 139 A]

2. Two 220-V, 1-phase electrical furnaces take loads of 350 kW and 500 kW respectively at a power factor of 0.8 lagging. The main supply is at 11-kV, 3-phase, 50 Hz. Calculate current in the 3-phase lines which energise a Scott-connected transformer combination. (Elect. Machines, Madras Univ. 1978)

[With 350 kW on teaser line currents are : 45.7 A ; 61.2 A ; 61.2 A]

3. Two electric furnaces are supplied with 1-phase current at 80 V from 3-phase, 11,000-V supply mains by means of two Scott-connected transformers with similar secondary windings. Calculate the current flowing kW respectively in each of the 3-phase lines at U.P.P. when the loads on the two transformers are 550 kW of 800 kW.

[With 550 kW on teaser, line currents are : 57.5 A; 78.2; 78.2 A] (Electrical Machines-I, Madras University, 1977)

### 33.11. Parallel Operation of 3-phase Transformers

All the conditions which apply to the parallel operation of single-phase transformers also apply to the parallel running of 3-phase transformers but with the following additions :

1. The voltage ratio must refer to the terminal **voltage of primary and secondary**. It is obvious that this ratio may not be equal to the ratio of the number of turns per phase. For example, if  $V_1$ ,  $V_2$  are the primary and secondary terminal voltages, then for  $Y/\Delta$  connection, the turn ratio is  $V_2 / (V_1 / \sqrt{3})$

$$= \sqrt{3} V_2 / V_1.$$

2. The phase displacement between primary and secondary voltages must be the same for all transformers which are to be connected for parallel operation.

3. The phase sequence must be the same.

4. All three transformers in the 3-phase transformer bank will be of the same construction either core or shell.

**Note. (i)** In dealing with 3-phase transformers, calculations are made for one phase only. The value of equivalent impedance used is the equivalent impedance per phase referred to secondary.

**(ii)** In case the impedances of primary and secondary windings are given separately, then primary impedance must be referred to secondary by multiplying it with (transformation ratio)<sup>2</sup>.

**(iii)** For Y/Δ or Δ/Y transformers, it should be remembered that the voltage ratios as given in the questions, refer to terminal voltages and are quite different from turn ratio.

**Example 33.26.** A load of 500 kVA at 0.8 power factor lagging is to be shared by two three-phase transformers A and B of equal ratings. If the equivalent delta impedances as referred to secondary are  $(2 + j6) \Omega$  for A and  $(2 + j5) \Omega$  for B, calculate the load supplied by each transformer.

**Solution.** 
$$S_A = S \frac{Z_B}{Z_A + Z_B} = S \frac{1}{1 + (Z_A/Z_B)}$$

Now 
$$S = 500 (0.8 - j0.6) = (400 - j300)$$

$$Z_A/Z_B = (2 + j6)/(2 + j5) = 1.17 + j0.07; Z_B/Z_A = (2 + j5)/(2 + j6) = 0.85 - j0.05$$

$$S_A = (400 - j300)/(2.17 + j0.07) = 180 - j144.2 = 230.7 \angle -38.7^\circ$$

$$\cos \phi_A = 0.78 \text{ lagging}$$

$$S_B = (400 - j300)/(1.85 - j0.05) = 220.1 - j156 = 270 \angle -40^\circ 28' \therefore \cos \phi_B = 0.76 \text{ lagging.}$$

**Example 33.27.** State (i) the essential and (ii) the desirable conditions to be satisfied so that two 3-phase transformers may operate successfully in parallel.

A 2,000-kVA transformer (A) is connected in parallel with a 4,000 kVA transformer (B) to supply a 3-phase load of 5,000 kVA at 0.8 p.f. lagging. Determine the kVA supplied by each transformer assuming equal no-load voltages. The percentage voltage drops in the windings at their rated loads are as follows :

Transformer A	resistance 2% ;	reactance 8 %
Transformer B	resistance 1.6 % ;	reactance 3 %

(Elect. Engineering-II, Bombay Univ. 1987)

**Solution.** On the basis of 4,000 kVA

$$\% Z_A = (4,000/2,000) (2 + j8) = (4 + j16) = 16.5 \angle 76^\circ$$

$$\% Z_B = (1.6 + j3); \% Z_A + \% Z_B = (5.6 + j16) = 19.8 \angle 73.6^\circ$$

$$S = 5,000 \angle -36.9^\circ = (4,000 - j3,000)$$

Now 
$$S_B = S \frac{Z_A}{Z_A + Z_B} = 5,000 \angle -36.9^\circ \times \frac{16.5 \angle 76^\circ}{19.8 \angle 73.6^\circ}$$

$$= 5,000 \angle -36.9^\circ \times 0.832 \angle 2.4^\circ = 4,160 \angle -34.5^\circ = (3,425 - j2,355)$$

$$S_A = S - S_B = (4,000 - j3,000) - (3,425 - j2,355)$$

$$= (575 - j645) = 864 \angle -48.3^\circ$$

$$\cos \phi_B = \cos 34.5^\circ = 0.824 \text{ (lag)}; \cos \phi_A = \cos 48.3^\circ = 0.665 \text{ (lag).}$$

**Example 33.28.** A load of 1,400 kVA at 0.866 p.f. lagging is supplied by two 3-phase transformers of 1,000 kVA and 500 kVA capacity operating in parallel. The ratio of transformation is the same in both : 6,600/400 delta-star. If the equivalent secondary impedances are  $(0.001 + j 0.003)$  ohm and  $(0.0028 + j0.005)$  ohm per phase respectively, calculate the load and power factor of each transformer.

(Elect. Engg-I, Nagpur Univ. 1993)

**Solution.** On the basis of 1000 kVA,  $Z_A = (0.001 + j0.003) \Omega$

$$Z_B = (1000/500) (0.0028 + j0.005) = (0.0056 + j0.01) \Omega$$

$$\frac{Z_A}{Z_A + Z_B} = \frac{(0.001 + j0.003)}{(0.0066 + j0.013)} = \frac{3.162 \times 10^{-3} \angle 71.6^\circ}{14.57 \times 10^{-3} \angle 63.1^\circ} = 0.2032 \angle 8.5^\circ$$

$$S = 1400 \angle \cos^{-1}(0.866) = 1400 \angle -30^\circ = (1212 - j700)$$

$$S_B = S \cdot \frac{Z_A}{Z_A + Z_B} = 1400 \angle -30^\circ \times 0.2032 \angle 8.5^\circ$$

$$= 284.5 \angle -21.5^\circ = 265 - j104$$

$$S_A = S - S_B = (1212 - j700) - (265 - j104) = (947 - j596) = 1145 \angle -32.2^\circ$$

$$\cos \phi_A = \cos 32.3^\circ = 0.846 \text{ (lag)}; \cos \phi_B = \cos 21.5^\circ = \mathbf{0.93 \text{ (lag)}}.$$

**Example 33.29.** Two 3-phase transformers A and B having the same no-load line voltage ratio 3,300/400-V supply a load of 750 kVA at 0.707 lagging when operating in parallel. The rating of A is 500 kVA, its resistance is 2% and reactance 3%. The corresponding values for B are 250 kVA; 1.5% and 4% respectively. Assuming that both transformers have star-connected secondary windings, calculate

- the load supplied by each transformer,
- the power factor at which each transformer is working,
- the secondary line voltage of the parallel circuit.

**Solution.** On the basis of 500 kVA,

$$\% Z_A = 2 + j3, \% Z_B = (500/200) (1.5 + j4) = (3 + j8)$$

$$\frac{Z_A}{Z_A + Z_B} = \frac{2 + j3}{5 + j1} = 0.3 \angle -9.3^\circ; \frac{Z_B}{Z_A + Z_B} = \frac{3 + j8}{5 + j11} = 0.711 \angle 3.8^\circ$$

Now,  $S = 750 \angle -45^\circ$

$$(a) \quad S_A = S \frac{Z_B}{Z_A + Z_B} = 750 \angle -45^\circ \times 0.711 \angle 3.8^\circ$$

$$= 533 \angle -41.2^\circ = (400 - j351)$$

$$S_B = 750 \angle -45^\circ \times 0.3 \angle 9.3^\circ = 225 \angle -54.3^\circ$$

$$(b) \quad \cos \phi_A = \cos 41.2^\circ = 0.752 \text{ (lag)}; \cos \phi_B = \cos 54.3^\circ = \mathbf{0.5835 \text{ (lag)}}$$

(c) Since voltage drop of each transformer is the same, its value in the case of transformer A would only be calculated. Now, for transformer A, kW = 400 for the active component of the current and kVAR = 351 for the reactive component.

$$\therefore \% \text{ resistive drop} = 2 \times 400/500$$

$$= 1.6\%; \% \text{ reactive drop} = 3 \times 351/500 = 2.1\%$$

$$\text{Total percentage drop} = 1.6 + 2.1 = 3.7$$

$$\text{Secondary line voltage} = 400 - (3.7 \times 400/100) = \mathbf{385.2 \text{ V}}.$$

### 33.12. Instrument Transformers

In d.c. circuit when large currents are to be measured, it is usual to use low-range ammeters with suitable shunts. For measuring high voltages, low-range voltmeters are used with a high resistance connected

in series with them. But it is not convenient to use these methods with alternating current and voltage instruments. For this purpose, specially constructed accurate ratio instrument transformers are employed in conjunction with standard low-range a.c. instruments. These instrument transformers are of two kinds : (i) current transformers for measuring large alternating currents and (ii) potential transformers for measuring high alternating voltages.

### 33.13. Current Transformers

These transformers are used with low-range ammeters to measure currents in high-voltage alternating-current circuits where it is not practicable to connect instruments and meters directly to the lines. In addition to insulating the instrument from the high voltage line, they step down the current in a known ratio. The current (or series) transformer has a primary coil of one or more turns of thick wire connected in **series** with the line whose current is to be measured as shown in Fig. 33.32. The secondary consists of a large number of turns of fine wire and is connected across the ammeter terminals (usually of 5-ampere bracket should be removed or 1-ampere range).

Current transformers

Fig. 33.32

Fig. 33.33

As regards voltage, the transformers is of step-up variety but it is obvious that current will be stepped down. Thus, if the current transformer has **primary to secondary** current ratio of 100 : 5, then it steps up the voltage 20 times whereas it steps down the current to 1/20th of its actual value. Hence, if we know current ratio ( $I_1/I_2$ ) of the transformer and the reading of the a.c. ammeter, the line current can be calculated. In fact, line current is given by the current transformation ratio times the reading on the ammeter. One of the most commonly used current transformer is the one known as **clamp-on or clip-on type**. It has a laminated core which is so arranged that it can be opened out at hinged section by merely pressing a trigger-like projection (Fig. 33.33). When the core is thus opened, it permits the admission of very heavy current-carrying bus bars or feeders whereupon the trigger is released and the core is tightly closed by a spring. The current carrying conductor or feeder acts as a single-turn primary whereas the secondary is connected across the standard ammeter conveniently mounted in the handle.

It should be noted that, since the ammeter resistance is very low, the current transformer normally works short circuited. If for any reason, the ammeter is taken out of the secondary winding, then this winding

Small current transformer

must be short-circuited with the help of short-circuiting switch  $S$ . If this is not done, then due to the absence of counter amp-turns of the secondary, the unopposed primary m.m.f. will set up an abnormally high flux in the core which will produce excessive core loss with subsequent heating and a high voltage across the secondary terminals. This is not the case with ordinary constant-potential transformers, because their primary current is determined by the load in their secondary whereas in a current transformer, the primary current is determined entirely by the load on the system and not by the load on its own secondary.

Hence, **the secondary of a current transformer should never be left open under any circumstances.**

**Example 33.30.** A 100 : 5 transformer is used in conjunction with a 5-amp ammeter. If the latter reads 3.5 A, find the line current.

**Solution.** Here, the ratio 100 : 5 stands for the ratio of primary-to-secondary currents *i.e.*  $I_1/I_2 = 100/5$

$\therefore$  Primary (or line) current =  $3.5 \times (100/5) = 70 \text{ A}$

**Example 33.31.** It is desired to measure a line current of the order of 2,000 A to 2,500 A. If a standard 5-amp ammeter is to be used along with a current transformer, what should be the turn ratio of the latter? By what factor should the ammeter reading be multiplied to get the line current in each case?

**Solution.**  $I_1/I_2 = 2000/5 = 400$  or  $2500/5 = 500$ . Since  $I_1/I_2 = N_2/N_1$  hence  $N_2/N_1 = 400$  in the first case and 500 in the second case. It means that  $N_1 : N_2 :: 1 : 400$  or  $1 : 500$ .

Ratio or multiplication factor in the first case is 400 and in the second in the second case 500.

### 33.14. Potential Transformers

These transformers are extremely accurate-ratio step-down transformers and are used in conjunction with standard low-range voltmeters (usually 150-V) whose deflection when divided by voltage transformation ratio, gives the true voltage on the high voltage side. In general, they are of the shell-type and do not differ much from the ordinary two-winding transformers discussed so far, except that their power rating is extremely small. Upto voltages of 5,000, potential transformers are usually of the dry type, between 5,000 and 13,800 volts, they may be either dry type or oil immersed type, although for voltages above 13,800 they are always oil immersed type. Since their secondary windings are required to operate instruments or relays or pilot lights, their ratings are usually of 40 to 100 W. For safety, the secondary should be completely insulated from the high-voltage primary and should be, in addition, grounded for affording protection to the operator. Fig. 33.34 shows the connections of such a transformer.

Small Potential transformer

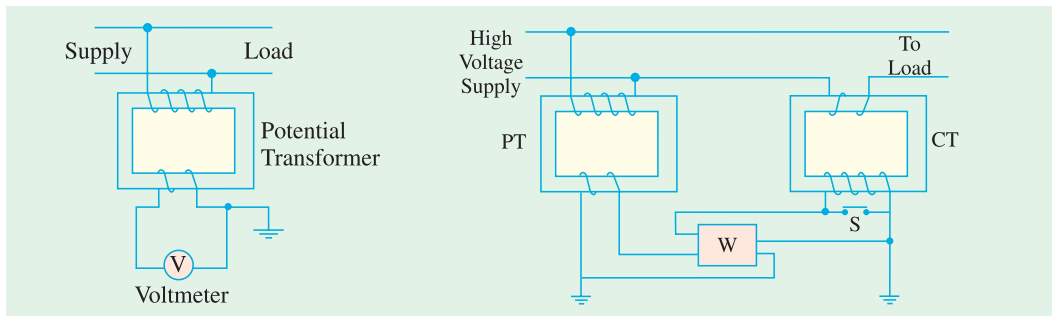

Fig. 33.34

Fig. 33.35

Fig. 33.35 shows the connections of instrument transformers to a wattmeter. While connecting the wattmeter, the relative polarities of the secondary terminals of the transformers with respect to their primary terminals must be known for connections of the instruments.

OBJECTIVE TEST – 33

- Which of the following connections is best suited for 3-phase, 4-wire service ?  
 (a)  $\Delta - \Delta$  (b) Y - Y  
 (c)  $\Delta - Y$  (d) Y -  $\Delta$
- In a three-phase Y-Y transformer connection, neutral is fundamental to the  
 (a) suppression of harmonics  
 (b) passage of unbalanced currents due to unbalanced loads  
 (c) provision of dual electric service  
 (d) balancing of phase voltages with respect to line voltages.
- As compared to  $\Delta - \Delta$  bank, the capacity of the V - V bank of transformers is ..... percent.  
 (a) 57.7 (b) 66.7  
 (c) 50 (d) 86.6
- If three transformers in a  $\Delta - \Delta$  are delivering their rated load and one transformer is removed, then overload on *each* of the remaining transformers is ..... percent.  
 (a) 66.7 (b) 173.2  
 (c) 73.2 (d) 58
- When a V - V system is converted into a  $\Delta - \Delta$  system, increase in capacity of the system is ..... percent.  
 (a) 86.6 (b) 66.7  
 (c) 73.2 (d) 50
- For supplying a balanced 3 -  $\phi$  load of 40-kVA, rating of each transformer in V - V bank should be nearly ..... kVA.  
 (a) 20 (b) 23  
 (c) 34.6 (d) 25
- When a closed -  $\Delta$  bank is converted into an open -  $\Delta$  bank, each of the two remaining transformers supplies ..... percent of the original load.  
 (a) 66.7 (b) 57.7  
 (c) 50 (d) 73.2
- If the load p.f. is 0.866, then the average p.f. of the V - V bank is  
 (a) 0.886 (b) 0.75  
 (c) 0.51 (d) 0.65
- A T - T connection has higher ratio of utilization than a V - V connection only when  
 (a) identical transformers are used  
 (b) load power factor is leading  
 (c) load power factor is unity  
 (d) non-identical transformers are used.
- The biggest advantage of T - T connection over the V - V connection for 3-phase power transformation is that it provides  
 (a) a set of balanced voltages under load  
 (b) a true 3-phase, 4-wire system  
 (c) a higher ratio of utilization  
 (d) more voltages.
- Of the following statements concerning parallel operation of transformers, the one which is **not** correct is  
 (a) transformers must have equal voltage ratings  
 (b) transformers must have same ratio of transformation  
 (c) transformers must be operated at the same frequency  
 (d) transformers must have equal kVA ratings.

**12. Statement**

An auto-transformer is more efficient in transferring energy from primary to secondary circuit.

**Reason**

Because it does so both inductively and conductively.

**Key**

- (a) statement is false, reason is correct and relevant  
 (b) statement is correct, reason is correct but irrelevant  
 (c) both statement and reason are correct and are connected to each other as cause and effect  
 (d) both statement and reason are false.
- 13.** Out of the following given choices for poly phase transformer connections which one will you select for three-to-two phase conversion ?

- (a) Scott (b) star/star  
 (c) double Scott (d) star/double-delta

- 14.** A T – T transformer cannot be paralleled with ..... transformer.

- (a) V – V (b) Y – Δ  
 (c) Y – Y (d) Δ – Δ

- 15.** Instrument transformers are used on a.c. circuits for extending the range of

- (a) ammeters (b) voltmeters  
 (c) wattmeters (d) all of the above.

- 16.** Before removing the ammeter from a current transformer, its secondary must be short-circuited in order to avoid

- (a) excessive heating of the core  
 (b) high secondary e.m.f.  
 (c) increase in iron losses  
 (d) all of the above.

**ANSWERS**

1. c 2. a 3. a 4. c 5. c 6. b 7. b 8. b 9. d 10. b 11. d 12. c 13. a 14. b 15. d 16. d

## INDUCTION MOTOR

↑ The high-speed magnetic levitation trains employ the principle of linear induction motor

### 34.1. Classification of A.C. Motors

With the almost universal adoption of a.c. system of distribution of electric energy for light and power, the field of application of a.c. motors has widened considerably during recent years. As a result, motor manufactures have tried, over the last few decades, to perfect various types of a.c. motors suitable for all classes of industrial drives and for both single and three-phase a.c. supply. This has given rise to bewildering multiplicity of types whose proper classification often offers considerable difficulty. Different a.c. motors may, however, be classified and divided into various groups from the following different points of view :

#### 1. AS REGARDS THEIR PRINCIPLE OF OPERATION

##### (A) Synchronous motors

(i) plain and (ii) super—

##### (B) Asynchronous motors

##### (a) Induction motors

(i) Squirrel cage { single  
double

(ii) Slip-ring (external resistance)

##### (b) Commutator motors

(i) Series { single phase  
universal

(ii) Compensated { conductively  
inductively

(iii) shunt { simple  
compensated

(iv) repulsion { straight  
compensated

(v) repulsion-start induction

(vi) repulsion induction

#### 2. AS REGARDS THE TYPE OF CURRENT

(i) single phase

(ii) three phase

#### 3. AS REGARDS THEIR SPEED

(i) constant speed

(ii) variable speed

(iii) adjustable speed

#### 4. AS REGARDS THEIR STRUCTURAL FEATURES

(i) open

(ii) enclosed

(iii) semi-enclosed

(iv) ventilated

(v) pipe-ventilated

(vi) riverted frame eye etc.

Three phase high voltage asynchronous motors

Fig. 34.1 Squirrel cage AC induction motor opened to show the stator and rotor construction, the shaft with bearings, and the cooling fan.

### 34.2. Induction Motor : General Principle

As a general rule, conversion of electrical power into mechanical power takes place in the **rotating** part of an electric motor. In d.c. motors, the electric power is **conducted** directly to the armature (*i.e.* rotating part) through brushes and commutator (Art. 29.1). Hence, in this sense, a d.c. motor can be called a **conduction** motor. However, in a.c. motors, the rotor does not receive electric power by conduction but by **induction** in exactly the same way as the secondary of a 2-winding transformer receives its power from

the primary. That is why such motors are known as *induction* motors. In fact, an induction motor can be treated as a *rotating transformer* i.e. one in which primary winding is stationary but the secondary is free to rotate (Art. 34.47).

Of all the a.c. motors, the polyphase induction motor is the one which is extensively used for various kinds of industrial drives. It has the following main advantages and also some dis-advantages:

**Advantages:**

1. It has very simple and extremely rugged, almost unbreakable construction (especially squirrel-cage type).
2. Its cost is low and it is very reliable.
3. It has sufficiently high efficiency. In normal running condition, no brushes are needed, hence frictional losses are reduced. It has a reasonably good power factor.
4. It requires minimum of maintenance.
5. It starts up from rest and needs no extra starting motor and has not to be synchronised. Its starting arrangement is simple especially for squirrel-cage type motor.

**Disadvantages:**

1. Its speed cannot be varied without sacrificing some of its efficiency.
2. Just like a d.c. shunt motor, its speed decreases with increase in load.
3. Its starting torque is somewhat inferior to that of a d.c. shunt motor.

**34.3. Construction**

An induction motor consists essentially of two main parts :

(a) a stator and (b) a rotor.

**(a) Stator**

The stator of an induction motor is, in principle, the same as that of a synchronous motor or generator. It is made up of a number of stampings, which are slotted to receive the windings [Fig.34.2 (a)]. The stator carries a 3-phase winding [Fig.34.2 (b)] and is fed from a 3-phase supply. It is wound for a definite number of poles\*, the exact number of poles being determined by the requirements of speed. Greater the number of poles, lesser the speed and *vice versa*. It will be shown in Art. 34.6 that the stator windings, when supplied with 3-phase currents, produce a magnetic flux, which is of constant magnitude but which revolves (or rotates) at synchronous speed (given by  $N_s = 120 / P$ ). This revolving magnetic flux induces an e.m.f. in the rotor by mutual induction.

**Fig. 34.2 (a)** Unwound stator with semi-closed slots. Laminations are of high-quality low-loss silicon steel. (Courtesy : Gautam Electric Motors)

**Fig. 34.2 (b)** Completely wound stator for an induction motor. (Courtesy : Gautam Electric Motors)

\* The number of poles  $P$ , produced in the rotating field is  $P = 2n$  where  $n$  is the number of stator slots/pole/phase.

**(b) Rotor**

**(i) Squirrel-cage rotor:** Motors employing this type of rotor are known as squirrel-cage induction motors.

**(ii) Phase-wound or wound rotor:** Motors employing this type of rotor are variously known as 'phase-wound' motors or 'wound' motors or as 'slip-ring' motors.

**34.4. Squirrel-cage Rotor**

Almost 90 per cent of induction motors are squirrel-cage type, because this type of rotor has the simplest and most rugged construction imaginable and is almost indestructible. The rotor consists of a cylindrical laminated core with parallel slots for carrying the rotor conductors which, it should be

**Fig. 34.3 (a)** Squirrel-cage rotor with copper bars and alloy brazed end-rings  
(Courtesy : Gautam Electric Motors)

**Fig. 34.3 (b)** Rotor with shaft and brings  
(Courtesy : Gautam Electric Motors)

noted clearly, are not wires but consist of heavy bars of copper, aluminium or alloys. One bar is placed in each slot, rather the bars are inserted from the end when semi-closed slots are used. The rotor bars are brazed or electrically welded or bolted to two heavy and stout short-circuiting end-rings, thus giving us, what is so picturesquely called, a squirrel-cage construction (Fig. 34.3).

It should be noted that the **rotor bars are permanently short-circuited on themselves**, hence it is not possible to add any external resistance in series with the rotor circuit for starting purposes.

The rotor slots are usually not quite parallel to the shaft but are purposely given a slight skew (Fig. 34.4). This is useful in two ways :

- (i)** it helps to make the motor run quietly by reducing the magnetic hum and
- (ii)** it helps in reducing the locking tendency of the rotor *i.e.* the tendency of the rotor teeth to remain under the stator teeth due to direct magnetic attraction between the two.\*

In small motors, another method of construction is used. It consists of placing the entire rotor core in a mould and casting all the bars and end-rings in one piece. The metal commonly used is an aluminium alloy.

Another form of rotor consists of a solid cylinder of steel without any conductors or slots at all. The motor operation depends upon the production of eddy currents in the steel rotor.

**Fig. 34.4**

\* Other results of skew which may or may not be desirable are (i) increase in the effective ratio of transformation between stator and rotor (ii) increased rotor resistance due to increased length of rotor bars (iii) increased impedance of the machine at a given slip and (iv) increased slip for a given torque.

### 34.5. Phase-wound Rotor

This type of rotor is provided with 3-phase, double-layer, distributed winding consisting of coils as used in alternators. The rotor is wound for as many poles as the number of stator poles and is always wound 3-phase even **when the stator is wound two-phase**.

The three phases are starred internally. The other three winding terminals are brought out and connected to three insulated slip-rings mounted on the shaft with brushes resting on them [Fig. 34.5 (b)]. These three brushes are further externally connected to a 3-phase star-connected rheostat [Fig. 34.5 (c)]. This makes possible the introduction of additional resistance in the rotor circuit during the starting period for increasing the starting torque of the motor, as shown in Fig. 34.6 (a) (Ex.34.7 and 34.10) and for changing its speed-torque/current characteristics. When running under normal conditions, the **slip-rings are automatically short-circuited** by means of a metal collar, which is pushed along the shaft and connects all the rings together. Next, the brushes are automatically lifted from the slip-rings to reduce the frictional losses and the wear and tear. Hence, it is seen that under normal running conditions, the wound rotor is short-circuited on itself just like the squirrel-case rotor.

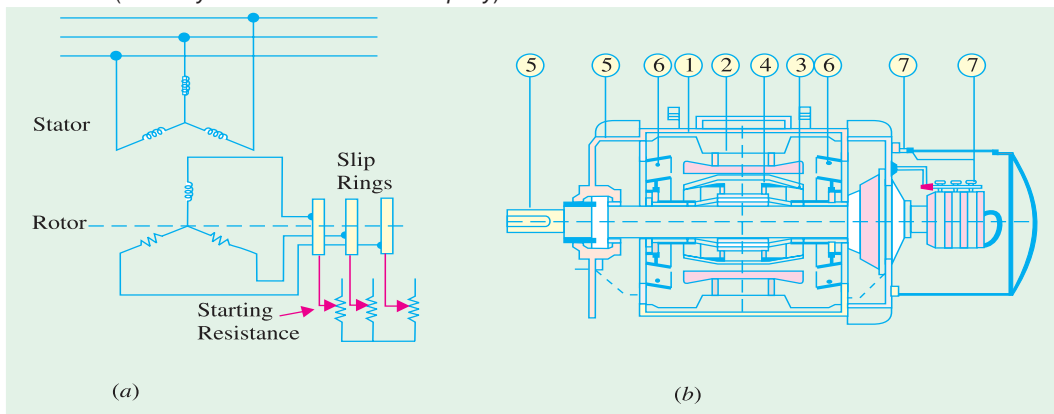

Fig. 34.5 (a)

Fig. 34.6 (b) shows the longitudinal section of a slip-ring motor, whose structural details are as under :

Fig. 34.5 (b) Slip-ring motor with slip-rings brushes and short-circuiting devices

(Courtesy : Jyoti Colour-Emag Ltd.)

1. **Frame.** Made of close-grained alloy cast iron.
2. **Stator and Rotor Core.** Built from high-quality low-loss silicon steel laminations and flash-enamelled on both sides.
3. **Stator and Rotor Windings.** Have moisture proof tropical insulation embodying mica and high quality varnishes. Are carefully spaced for most effective air circulation and are rigidly braced to withstand centrifugal forces and any short-circuit stresses.
4. **Air-gap.** The stator rabbets and bore are machined carefully to ensure uniformity of air-gap.
5. **Shafts and Bearings.** Ball and roller bearings are used to suit heavy duty, trouble-free running and for enhanced service life.
6. **Fans.** Light aluminium fans are used for adequate circulation of cooling air and are securely keyed onto the rotor shaft.
7. **Slip-rings and Slip-ring Enclosures.** Slip-rings are made of high quality phosphor-bronze and are of moulded construction.

Fig. 34.6 (c) shows the disassembled view of an induction motor with squirrel-cage rotor. According to the labelled notation (a) represents stator (b) rotor (c) bearing shields (d) fan (e) ventilation grill and (f) terminal box.

Similarly, Fig. 34.6 (d) shows the disassembled view of a slip-ring motor where (a) represents stator (b) rotor (c) bearing shields (d) fan (e) ventilation grill (f) terminal box (g) slip-rings (h) brushes and brush holders.

### 34.6. Production of Rotating Field

It will now be shown that when stationary coils, wound for two or three phases, are supplied by two or three-phase supply respectively, a uniformly-rotating (or revolving) magnetic flux of constant value is produced.

#### Two-phase Supply

The principle of a 2- $\phi$ , 2-pole stator having two identical windings, 90 space degrees apart, is illustrated in Fig. 34.7.

Induction motor

The flux due to the current flowing in each phase winding is assumed sinusoidal and is represented in Fig. 34.9. The assumed positive directions of fluxes are those shown in Fig. 34.8.

Let  $\Phi_1$  and  $\Phi_2$  be the instantaneous values of the fluxes set up by the two windings. The resultant flux  $\Phi_r$  at any time is the vector sum of these two fluxes ( $\Phi_1$  and  $\Phi_2$ ) at that time. We will consider conditions at intervals of  $1/8$ th of a time period *i.e.* at intervals corresponding to angles of  $0^\circ$ ,  $45^\circ$ ,  $90^\circ$ ,  $135^\circ$  and  $180^\circ$ . It will be shown that resultant flux  $\Phi_r$  is constant in magnitude *i.e.* equal to  $\Phi_m$  - the maximum flux due to either phase and is making one revolution/cycle. In other words, it means that the resultant flux rotates synchronously.

Fig. 34.7

- (a) When  $\theta = 0^\circ$  *i.e.* corresponding to point 0 in Fig. 34.9,  $\Phi_1 = 0$ , but  $\Phi_2$  is maximum *i.e.* equal to  $\Phi_m$  and negative. Hence, resultant flux  $\Phi_r = \Phi_m$  and, being negative, is shown by a vector pointing downwards [Fig. 34.10 (i)].
- (b) When  $\theta = 45^\circ$  *i.e.* corresponding to point 1 in Fig. 34.9. At this instant,  $\Phi_1 = \Phi_m / \sqrt{2}$  and is positive;  $\Phi_2 = \Phi_m / \sqrt{2}$  but is still negative. Their resultant, as shown in Fig. 34.10 (ii), is  $\Phi_r = \sqrt{[(\Phi_m / \sqrt{2})^2 + (\Phi_m / \sqrt{2})^2]} = \Phi_m$  although this resultant has shifted  $45^\circ$  clockwise.
- (c) When  $\theta = 90^\circ$  *i.e.* corresponding to point 2 in Fig. 34.9. Here  $\Phi_2 = 0$ , but  $\Phi_1 = \Phi_m$  and is positive. Hence,  $\Phi_r = \Phi_m$  and has further shifted by an angle of  $45^\circ$  from its position in (b) or by  $90^\circ$  from its original position in (a).
- (d) When  $\theta = 135^\circ$  *i.e.* corresponding to point 3 in Fig. 34.9. Here,  $\Phi_1 = \Phi_m / \sqrt{2}$  and is positive,  $\Phi_2 = \Phi_m / \sqrt{2}$  and is also positive. The resultant  $\Phi_r = \Phi_m$  and has further shifted clockwise by another  $45^\circ$ , as shown in Fig. 34.10 (iv).

Fig. 34.8

Fig. 34.9

- (e) When  $\theta = 180^\circ$  *i.e.* corresponding to point 4 in Fig. 34.9. Here,  $\Phi_1 = 0$ ,  $\Phi_2 = \Phi_m$  and is positive. Hence,  $\Phi_r = \Phi_m$  and has shifted clockwise by another  $45^\circ$  or has rotated through an angle of  $180^\circ$  from its position at the beginning. This is shown in Fig. 34.10 (v).

Fig. 34.10

Hence, we conclude

1. that the magnitude of the resultant flux is constant and is equal to  $\Phi_m$  — the maximum flux due to either phase.
2. that the resultant flux rotates at synchronous speed given by  $N_s = 120 f/P$  rpm.

However, it should be clearly understood that in this revolving field, there is no actual revolution of the flux. The flux due to each phase changes periodically, according to the changes in the phase current, but the magnetic flux itself does not move around the stator. It is only the seat of the resultant flux which keeps on shifting synchronously around the stator.

**Mathematical Proof**

Let  $\Phi_1 = \Phi_m \sin \omega t$  and  $\Phi_2 = \Phi_m \sin (\omega t - 90^\circ)$

$\therefore \Phi_r^2 = \Phi_1^2 + \Phi_2^2$

$\Phi_r^2 = (\Phi_m \sin \omega t)^2 + [\Phi_m \sin (\omega t - 90^\circ)]^2 = \Phi_m^2 (\sin^2 \omega t + \cos^2 \omega t) = \Phi_m^2$

$\therefore \Phi_r = \Phi_m$

It shows that the flux is of constant value and does not change with time.

**34.7. Three-phase Supply**

It will now be shown that when three-phase windings displaced in space by  $120^\circ$ , are fed by three-phase currents, displaced in time by  $120^\circ$ , they produce a resultant magnetic flux, which rotates in space as if actual magnetic poles were being rotated mechanically.

The principle of a 3-phase, two-pole stator having three identical windings placed  $120$  space degrees apart is shown in Fig. 34.11. The flux (assumed sinusoidal) due to three-phase windings is shown in Fig 34.12.

The assumed positive directions of the fluxes are shown in Fig 34.13. Let the maximum value of flux due to any one of the three phases be  $\Phi_m$ . The resultant flux  $\Phi_r$ , at any instant, is given by the vector sum of the individual fluxes,  $\Phi_1$ ,  $\Phi_2$  and  $\Phi_3$  due to three phases. We will consider values of  $\Phi_r$  at four instants  $1/6$ th time-period apart corresponding to points marked 0, 1, 2 and 3 in Fig. 34.12.

(i) When  $\theta = 0^\circ$  i.e. corresponding to point 0 in Fig. 34.12.

Here  $\Phi_1 = 0$ ,  $\Phi_2 = -\frac{\sqrt{3}}{2} \Phi_m$ ,  $\Phi_3 = \frac{\sqrt{3}}{2} \Phi_m$ . The vector for  $\Phi_2$  in Fig. 34.14 (i) is drawn in a direction opposite to the direction assumed positive in Fig. 34.13.

$$\therefore \Phi_r = 2 \times \frac{\sqrt{3}}{2} \Phi_m \cos \frac{60^\circ}{2} = \sqrt{3} \times \frac{\sqrt{3}}{2} \Phi_m = \frac{3}{2} \Phi_m$$

Fig. 34.11

Fig. 34.12

Fig. 34.13

(ii) when  $\theta = 60^\circ$  i.e. corresponding to point 1 in Fig. 34.12.

Here  $\Phi_1 = \frac{\sqrt{3}}{2} \Phi_m$  ...drawn parallel to  $OI$  of Fig. 34.13 as shown in Fig. 34.14 (ii)

$\Phi_2 = -\frac{\sqrt{3}}{2} \Phi_m$  ...drawn in opposition to  $OII$  of Fig. 34.13.

$\Phi_3 = 0$

$$\therefore \Phi_r = 2 \times \frac{\sqrt{3}}{2} \Phi_m \times \cos 30^\circ = \frac{3}{2} \Phi_m \quad \text{[Fig. 34.14 (ii)]}$$

It is found that the resultant flux is again  $\frac{3}{2} \Phi_m$  but has rotated clockwise through an angle of  $60^\circ$ .

(iii) When  $\theta = 120^\circ$  i.e. corresponding to point 2 in Fig. 34.12.

Here,  $\Phi_1 = \frac{\sqrt{3}}{2} \Phi_m$ ,  $\Phi_2 = 0$ ,  $\Phi_3 = -\frac{\sqrt{3}}{2} \Phi_m$

It can be again proved that  $\Phi_r = \frac{3}{2} \Phi_m$

So, the resultant is again of the same value, but has further rotated clockwise through an angle of  $60^\circ$  [Fig. 34.14 (iii)].

Fig. 34.14

(iv) When  $\theta = 180^\circ$  i.e. corresponding to point 3 in Fig. 34.12.

$$\Phi_1 = 0, \Phi_2 = \frac{\sqrt{3}}{2} \Phi_m, \Phi_3 = -\frac{\sqrt{3}}{2} \Phi_m$$

The resultant is  $\frac{3}{2} \Phi_m$  and has rotated clockwise through an additional angle  $60^\circ$  or through an angle of  $180^\circ$  from the start.

Hence, we conclude that

1. the resultant flux is of constant value =  $\frac{3}{2} \Phi_m$  i.e. **1.5 times the maximum value of the flux due to any phase.**
2. **the resultant flux rotates around the stator at synchronous speed given by  $N_s = 120 f/P$ .**

Fig. 34.15 (a) shows the graph of the rotating flux in a simple way. As before, the positive directions of the flux phasors have been shown separately in Fig. 34.15 (b). Arrows on these flux phasors are reversed when each phase passes through zero and becomes negative.

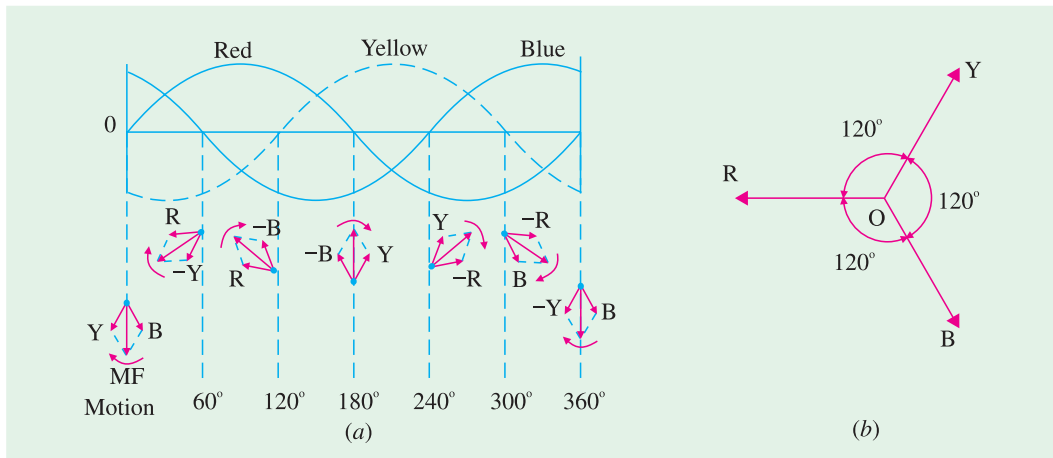

Fig. 34.15

As seen, positions of the resultant flux phasor have been shown at intervals of 60° only. The resultant flux produces a field rotating in the clockwise direction.

### 34.8. Mathematical Proof

Taking the direction of flux due to phase 1 as reference direction, we have

$$\begin{aligned} \Phi_1 &= \Phi_m (\cos 0^\circ + j \sin 0^\circ) \sin \omega t \\ \Phi_2 &= \Phi_m (\cos 240^\circ + j \sin 240^\circ) \sin (\omega t - 120^\circ) \\ \Phi_3 &= \Phi_m (\cos 120^\circ + j \sin 120^\circ) \sin (\omega t - 240^\circ) \end{aligned}$$

Expanding and adding the above equations, we get

$$\Phi_r = \frac{3}{2} \Phi_m (\sin \omega t + j \cos \omega t) = \frac{3}{2} \Phi_m \angle 90^\circ - \omega t$$

The resultant flux is of constant magnitude and does not change with time 't'.

### 34.9. Why Does the Rotor Rotate ?

The reason why the rotor of an induction motor is set into rotation is as follow:

When the 3-phase stator windings, are fed by a 3-phase supply then, as seen from above, a magnetic flux of constant magnitude, but rotating at synchronous speed, is set up. The flux passes through the air-gap, sweeps past the rotor surface and so cuts the rotor conductors which, as yet, are stationary. Due to the relative speed between the rotating flux and the stationary conductors, an e.m.f. is induced in the latter, according to Faraday's laws of electro-magnetic induction. **The frequency of the induced e.m.f. is the same as the supply frequency.** Its magnitude is proportional to the relative velocity between the flux and the conductors and its direction is given by Fleming's Right-hand rule. Since the rotor bars or conductors form a closed circuit, rotor current is produced whose direction, as given by Lenz's law, is such as to oppose the very cause producing it. In this case, the cause which produces the rotor current is the relative velocity between the rotating flux of the stator and the stationary rotor conductors. Hence, to reduce the relative speed, the rotor starts running in the **same** direction as that of the flux and tries to catch up with the rotating flux.

Windings of induction electric motor

The setting up of the torque for rotating the rotor is explained below :

In Fig 34.16 (a) is shown the stator field which is assumed to be rotating clockwise. The relative motion of the rotor with respect to the stator is **anticlockwise**. By applying Right-hand rule, the direction of the induced e.m.f. in the rotor is found to be outwards. Hence, the direction of the flux due to rotor current **alone**, is as shown in Fig. 34.16 (b). Now, by applying the Left-hand rule, or by the effect of combined field [Fig. 34.16(c)] it is clear that the rotor conductors experience a force tending to rotate them in clockwise direction. Hence, the rotor is set into rotation in the same direction as that of the stator flux (or field).

Fig. 34.16

### 34.10. Slip

In practice, the rotor never succeeds in ‘catching up’ with the stator field. If it really did so, then there would be no relative speed between the two, hence no rotor e.m.f., no rotor current and so no torque to maintain rotation. That is why the rotor runs at a speed which is always less than the speed of the stator field. The difference in speeds depends upon the load on the motor.\*

The difference between the synchronous speed  $N_s$  and the actual speed  $N$  of the rotor is known as **slip**. Though it may be expressed in so many revolutions/second, yet it is usual to express it as a percentage of the synchronous speed. Actually, the term ‘**slip**’ is descriptive of the way in which the rotor ‘slips back’ from synchronism.

$$\% \text{ slip } s = \frac{N_s - N}{N_s} \times 100$$

Sometimes,  $N_s - N$  is called the **slip speed**.

Obviously, rotor (or motor) speed is  $N = N_s (1 - s)$ .

It may be kept in mind that revolving flux is rotating synchronously, relative to the stator (*i.e.* stationary space) but at slip speed relative to the rotor.

### 34.11. Frequency of Rotor Current

When the rotor is stationary, the frequency of rotor current is **the same as the supply frequency**. But when the rotor starts revolving, then the frequency depends upon the relative speed or on slip-speed. Let at any slip-speed, the frequency of the rotor current be  $f'$ . Then

$$N_s - N = \frac{120 f'}{P} \quad \text{Also,} \quad N_s = \frac{120 f}{P}$$

Dividing one by the other, we get,  $\frac{f'}{f} = \frac{N_s - N}{N_s} = s \qquad \therefore f' = sf$

As seen, rotor currents have a frequency of  $f' = sf$  and when flowing through the individual

\* It may be noted that as the load is applied, the natural effect of the load or braking torque is to slow down the motor. Hence, slip increases and with it increases the current and torque, till the driving torque of the motor balances the retarding torque of the load. This fact determines the speed at which the motor runs on load.

phases of rotor winding, give rise to rotor magnetic fields. These individual rotor magnetic fields produce a combined rotating magnetic field, whose speed relative to rotor is

$$= \frac{120 f'}{P} = \frac{120 sf}{P} = sN_s$$

However, the rotor itself is running at speed  $N$  with respect to space. Hence, speed of rotor field in **space** = speed of rotor magnetic field relative to rotor + speed of rotor relative to space

$$= sN_s + N = sN_s + N_s (1 - s) = N_s$$

It means that no matter what the value of slip, rotor currents and stator currents each produce a sinusoidally distributed magnetic field of constant magnitude and constant space speed of  $N_s$ . In other words, both the rotor and stator fields rotate synchronously, which means that they are stationary with respect to each other. These two synchronously rotating magnetic fields, in fact, superimpose on each other and give rise to the actually existing rotating field, which corresponds to the magnetising current of the stator winding.

**Example 34.1.** A slip-ring induction motor runs at 290 r.p.m. at full load, when connected to 50-Hz supply. Determine the number of poles and slip.

(Utilisation of Electric Power AMIE Sec. B 1991)

**Solution.** Since  $N$  is 290 rpm;  $N_s$  has to be somewhere near it, say 300 rpm. If  $N_s$  is assumed as 300 rpm, then  $300 = 120 \times 50/P$ . Hence,  $P = 20$ .  $\therefore s = (300 - 290)/300 = 3.33\%$

**Example 34.2.** The stator of a 3- $\phi$  induction motor has 3 slots per pole per phase. If supply frequency is 50 Hz, calculate

- (i) number of stator poles produced and total number of slots on the stator
- (ii) speed of the rotating stator flux (or magnetic field).

**Solution. (i)**  $P = 2n = 2 \times 3 = 6$  poles  
 Total No. of slots = 3 slots/pole/phase  $\times$  6 poles  $\times$  3 phases = 54  
**(ii)**  $N_s = 120 f/P = 120 \times 50/6 = 1000$  r.p.m.

**Example 34.3.** A 4-pole, 3-phase induction motor operates from a supply whose frequency is 50 Hz. Calculate :

- (i) the speed at which the magnetic field of the stator is rotating.
- (ii) the speed of the rotor when the slip is 0.04.
- (iii) the frequency of the rotor currents when the slip is 0.03.
- (iv) the frequency of the rotor currents at standstill.

(Electrical Machinery II, Bangalore Univ. 1991)

**Solution. (i)** Stator field revolves at synchronous speed, given by

$$N_s = 120 f/P = 120 \times 50/4 = 1500 \text{ r.p.m.}$$

- (ii)** rotor (or motor) speed,  $N = N_s(1 - s) = 1500(1 - 0.04) = 1440$  r.p.m.
- (iii)** frequency of rotor current,  $f' = sf = 0.03 \times 50 = 1.5$  r.p.s = 90 r.p.m
- (iv)** Since at standstill,  $s = 1$ ,  $f' = sf = 1 \times f = f = 50$  Hz

**Example 34.4.** A 3- $\phi$  induction motor is wound for 4 poles and is supplied from 50-Hz system. Calculate (i) the synchronous speed (ii) the rotor speed, when slip is 4% and (iii) rotor frequency when rotor runs at 600 rpm.

(Electrical Engineering-I, Pune Univ. 1991)

**Solution. (i)**  $N_s = 120 f/P = 120 \times 50/4 = 1500$  rpm  
**(ii)** rotor speed,  $N = N_s(1 - s) = 1500(1 - 0.04) = 1440$  rpm

(iii) when rotor speed is 600 rpm, slip is

$$s = (N_s - N)/N_s = (1500 - 600)/1500 = 0.6$$

rotor current frequency,  $f' = sf = 0.6 \times 50 = \mathbf{30 \text{ Hz}}$

**Example 34.5.** A 12-pole, 3-phase alternator driven at a speed of 500 r.p.m. supplies power to an 8-pole, 3-phase induction motor. If the slip of the motor, at full-load is 3%, calculate the full-load speed of the motor

**Solution.** Let  $N$  = actual motor speed; Supply frequency,  $f = 12 \times 500/120 = 50 \text{ Hz}$ . Synchronous speed  $N_s = 120 \times 50/8 = 750 \text{ r.p.m.}$

$$\% \text{ slip } s = \frac{N_s - N}{N} \times 100; \quad 3 = \frac{750 - N}{750} \times 100 \quad \therefore N = \mathbf{727.5 \text{ r.p.m.}}$$

**Note.** Since slip is 3%, actual speed  $N$  is less than  $N_s$  by 3% of  $N_s$  i.e. by  $3 \times 750/100 = 22.5 \text{ r.p.m.}$

### 34.12. Relation Between Torque and Rotor Power Factor

In Art. 29.7, it has been shown that in the case of a d.c. motor, the torque  $T_a$  is proportional to the product of armature current and flux per pole i.e.  $T_a \propto \phi I_a$ . Similarly, in the case of an induction motor, the torque is also proportional to the product of flux per stator pole and the rotor current. However, there is one more factor that has to be taken into account i.e. the power factor of the rotor.

$$\therefore T \propto \phi I_2 \cos \phi_2 \quad \text{or} \quad T = k \phi I_2 \cos \phi_2$$

where  $I_2$  = rotor current at standstill

$\phi_2$  = angle between rotor e.m.f. and rotor current

$k$  = a constant

Denoting rotor e.m.f. at **standstill** by  $E_2$ , we have that  $E_2 \propto \phi$

$$\therefore T \propto E_2 I_2 \cos \phi_2$$

or  $T = k_1 E_2 I_2 \cos \phi_2$

where  $k_1$  is another constant.

The effect of rotor power factor on rotor torque is illustrated in Fig. 34.17 and Fig. 34.18 for various values of  $\phi_2$ . From the above expression for torque, it is clear that as  $\phi_2$  increases (and hence,  $\cos \phi_2$  decreases) the torque decreases and **vice versa**.

In the discussion to follow, the stator flux distribution is assumed sinusoidal. This revolving flux induces in each rotor conductor or bar an e.m.f. whose value depends on the flux density, in which the conductor is lying at the instant considered ( $\because e = Blv$  volt). Hence, the induced e.m.f. in the rotor is also sinusoidal.

#### (i) Rotor Assumed Non-inductive (or $\phi_2 = 0$ )

In this case, the rotor current  $I_2$  is in phase with the e.m.f.  $E_2$  induced in the rotor (Fig. 34.17). The instantaneous value of the torque acting on each rotor conductor is given by the product of instantaneous value of the flux and the rotor current ( $\because F \propto BI_2l$ ). Hence, torque curve is obtained by plotting the products of flux  $\phi$  (or flux density  $B$ ) and  $I_2$ . It is seen that the torque is always positive i.e. unidirectional.

#### (ii) Rotor Assumed Inductive

This case is shown in Fig. 34.18. Here,  $I_2$  lags behind  $E_2$  by an angle  $\phi_2 = \tan^{-1} X_2/R_2$  where  $R_2$  = rotor resistance/phase;  $X_2$  = rotor reactance/phase at **standstill**.

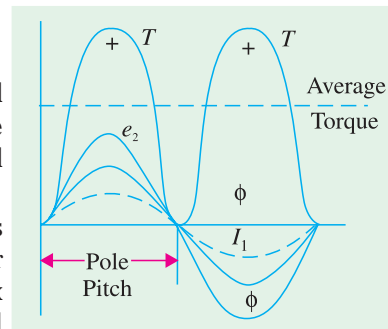

Fig. 34.17

It is seen that for a portion 'ab' of the pole pitch, the torque is negative *i.e.* reversed. Hence, the total torque which is the difference of the forward and the backward torques, is considerably reduced. If  $\phi_2 = 90^\circ$ , then the total torque is zero because in that case the backward and the forward torques become equal and opposite.

Fig. 34.18

Fig. 34.19

### 34.13. Starting Torque

The torque developed by the motor at the instant of starting is called starting torque. In some cases, it is greater than the normal running torque, whereas in some other cases it is somewhat less.

Let  $E_2 =$  rotor *e.m.f.* per phase at **standstill**;  
 $R_2 =$  rotor resistance/phase  
 $X_2 =$  rotor reactance/phase at **standstill**

$$\therefore Z_2 = \sqrt{(R_2^2 + X_2^2)} = \text{rotor impedance/phase at standstill} \quad \dots \text{Fig. 34.19}$$

Then, 
$$I_2 = \frac{E_2}{Z_2} = \frac{E_2}{\sqrt{(R_2^2 + X_2^2)}}; \quad \cos \phi_2 = \frac{R_2}{Z_2} = \frac{R_2}{\sqrt{(R_2^2 + X_2^2)}}$$

Standstill or starting torque  $T_{st} = k_1 E_2 I_2 \cos \phi_2 \quad \dots \text{Art. 34.12}$

or 
$$T_{st} = k_1 E_2 \cdot \frac{E_2}{\sqrt{(R_2^2 + X_2^2)}} \times \frac{R_2}{\sqrt{(R_2^2 + X_2^2)}} = \frac{k_1 E_2^2 R_2}{R_2^2 + X_2^2} \quad \dots (i)$$

If supply voltage  $V$  is constant, then the flux  $\Phi$  and hence,  $E_2$  both are constant.

$\therefore T_{st} = k_2 \frac{R_2}{R_2^2 + X_2^2} = k_2 \frac{R_2}{Z_2^2}$  where  $k_2$  is some other constant.

Now,  $k_1 = \frac{3}{2\pi N_s}$ ,  $\therefore T_{st} = \frac{3}{2\pi N_s} \cdot \frac{E_2^2 R_2}{R_2^2 + X_2^2}$

Where  $N_s \rightarrow$  synchronous speed in rps.

### 34.14. Starting Torque of a Squirrel-cage Motor

The resistance of a squirrel-cage motor is fixed and small as compared to its reactance which is very large especially at the start because at standstill, the frequency of the rotor currents equals the supply frequency. Hence, the starting current  $I_2$  of the rotor, though very large in magnitude, lags by a very large angle behind  $E_2$ , with the result that the starting torque per ampere is very poor. It is roughly 1.5 times the full-load torque, although the starting current is 5 to 7 times the full-load current. Hence, such motors are not useful where the motor has to start against heavy loads.

### 34.15. Starting Torque of a Slip-ring Motor

The starting torque of such a motor is increased by improving its power factor by adding external resistance in the rotor circuit from the star-connected rheostat, the rheostat resistance being progres-

sively cut out as the motor gathers speed. Addition of external resistance, however, increases the rotor impedance and so reduces the rotor current. At first, the effect of improved power factor predominates the current-decreasing effect of impedance. Hence, starting torque is increased. But after a certain point, the effect of increased impedance predominates the effect of improved power factor and so the torque starts decreasing.

### 34.16. Condition for Maximum Starting Torque

It can be proved that starting torque is maximum when rotor resistance equals rotor reactance.

$$\text{Now } T_{st} = \frac{k_2 R_2}{R_2^2 + X_2^2} \quad \therefore \frac{dT_{st}}{dR_2} = k_2 \left[ \frac{1}{R_2^2 + X_2^2} - \frac{R_2 (2R_2)}{(R_2^2 + X_2^2)^2} \right] = 0$$

$$\text{or } R_2^2 + X_2^2 = 2R_2^2 \quad \therefore R_2 = X_2.$$

### 34.17. Effect of Change in Supply Voltage on Starting Torque

We have seen in Art. 34.13 that  $T_{st} = \frac{k_1 E_2^2 R_2}{R_2^2 + X_2^2}$ . Now  $E_2 \propto$  supply voltage  $V$

$$\therefore T_{st} = \frac{k_3 V^2 R_2}{R_2^2 + X_2^2} = \frac{k_3 V^2 R_2}{Z_2^2} \quad \text{where } k_3 \text{ is yet another constant. Hence } T_{st} \propto V^2.$$

Clearly, the torque is very sensitive to any changes in the supply voltage. A change of 5 per cent in supply voltage, for example, will produce a change of approximately 10% in the rotor torque. This fact is of importance in star-delta and auto transformer starters (Art. 33-11).

**Example 34.6.** A 3-6 induction motor having a star-connected rotor has an induced e.m.f. of 80 volts between slip-rings at standstill on open-circuit. The rotor has a resistance and reactance per phase of 1  $\Omega$  and 4  $\Omega$  respectively. Calculate current/phase and power factor when (a) slip-rings are short-circuited (b) slip-rings are connected to a star-connected rheostat of 3  $\Omega$  per phase.

(Electrical Technology, Bombay Univ. 1987, and similar example: Rajiv Gandhi Techn. Univ. Bhopal, Dec. 2000)

**Solution.** Standstill e.m.f./rotor phase =  $80/\sqrt{3} = 46.2$  V

$$\begin{aligned} \text{(a) Rotor impedance/phase} &= \sqrt{(1^2 + 4^2)} = 4.12 \Omega \\ \text{Rotor current/phase} &= 46.2/4.12 = \mathbf{11.2} \text{ A} \\ \text{Power factor} &= \cos \phi = 1/4.12 = \mathbf{0.243} \end{aligned}$$

As p.f. is low, the starting torque is also low.

$$\begin{aligned} \text{(b) Rotor resistance/phase} &= 3 + 1 = 4 \Omega \\ \text{Rotor impedance/phase} &= \sqrt{(4^2 + 4^2)} = 5.66 \Omega \\ \therefore \text{Rotor current/phase} &= 46.2/5.66 = \mathbf{8.16} \text{ A}; \quad \cos \phi = 4/5.66 = \mathbf{0.707}. \end{aligned}$$

Hence, the starting torque is increased due to the improvement in the power factor. It will also be noted that improvement in p.f. is much more than the decrease in current due to increased impedance.

**Example 34.7.** A 3-phase, 400-V, star-connected induction motor has a star-connected rotor with a stator to rotor turn ratio of 6.5. The rotor resistance and standstill reactance per phase are 0.05  $\Omega$  and 0.25  $\Omega$  respectively. What should be the value of external resistance per phase to be inserted in the rotor circuit to obtain maximum torque at starting and what will be rotor starting current with this resistance?

**Solution.** Here  $K = \frac{1}{6.5}$  because transformation ratio  $K$  is defined as

$$= \frac{\text{rotor turns/phase}}{\text{stator turns/phase}}$$

$$\text{Standstill rotor e.m.f./phase, } E_2 = \frac{400}{\sqrt{3}} \times \frac{1}{6.5} = 35.5 \text{ volt}$$

It has been shown in Art. 34.16 that starting torque is maximum when  $R_2 = X_2$  i.e. when  $R_2 = 0.25 \Omega$  in the present case

$$\therefore \text{ External resistance/phase required} = 0.25 - 0.05 = \mathbf{0.2 \Omega}$$

$$\text{Rotor impedance/phase} = \sqrt{(0.25^2 + 0.25^2)} = 0.3535 \Omega$$

$$\text{Rotor current/phase, } I_2 = 35.5/0.3535 = \mathbf{100 \text{ A (approx)}}$$

**Example 34.8.** A 1100-V, 50-Hz delta-connected induction motor has a star-connected slip-ring rotor with a phase transformation ratio of 3.8. The rotor resistance and standstill leakage reactance are 0.012 ohm and 0.25 ohm per phase respectively. Neglecting stator impedance and magnetising current determine.

- (i) the rotor current at start with slip-rings shorted
- (ii) the rotor power factor at start with slip-rings shorted
- (iii) the rotor current at 4% slip with slip-rings shorted
- (iv) the rotor power factor at 4% slip with slip-rings shorted
- (v) the external rotor resistance per phase required to obtain a starting current of 100 A in the stator supply lines. (Elect. Machines AMIE Sec. B 1992)

**Solution.** It should be noted that in a  $\Delta/Y$  connection, primary phase voltage is the same as the line voltage. The rotor phase voltage can be found by using the phase transformation ratio of 3.8 i.e.  $K = 1/3.8$ .

$$\text{Rotor phase voltage at standstill} = 1100 \times 1/3.8 = 289.5 \text{ V}$$

$$(i) \text{ Rotor impedance/phase} = \sqrt{0.012^2 + 0.25^2} = 0.2503 \Omega$$

$$\text{Rotor phase current at start} = 289.5/0.2503 = \mathbf{1157 \text{ A}}$$

$$(ii) \text{ p.f.} = R_2/Z_2 = 0.012/0.2503 = \mathbf{0.048 \text{ lag}}$$

$$(iii) \text{ at 4\% slip, } X_r = sX_2 = 0.04 \times 0.25 = 0.01 \Omega$$

$$\therefore Z_r = \sqrt{0.012^2 + 0.01^2} = \mathbf{0.0156 \Omega}$$

$$E_r = sE_2 = 0.04 \times 289.5 = 11.58 \text{ V; } I_2 = 11.58/0.0156 = \mathbf{742.3 \text{ A}}$$

$$(iv) \text{ p.f.} = 0.012/0.0156 = \mathbf{0.77}$$

$$(v) I_2 = I_1/K = 100 \times 3.8 = 380 \text{ A; } E_2 \text{ at standstill} = 289.5 \text{ V}$$

$$Z_2 = 289.5/380 = 0.7618 \Omega; R_2 = \sqrt{Z_2^2 - X_2^2} = \sqrt{0.7618^2 - 0.25^2} = 0.7196 \Omega$$

$$\therefore \text{ External resistance reqd./phase} = 0.7196 - 0.012 = \mathbf{0.707 \Omega}$$

**Example 34.9.** A 150-kw, 3000-V, 50-Hz, 6-pole star-connected induction motor has a star-connected slip-ring rotor with a transformation ratio of 3.6 (stator/rotor). The rotor resistance is 0.1 $\Omega$ /phase and its per phase leakage reactance is 3.61 mH. The stator impedance may be neglected. Find the starting current and starting torque on rated voltage with short-circuited slip rings.

(Elect. Machines, A.M.I.E. Sec. B, 1989)

$$\text{Solution. } X_2 = 2\pi \times 50 \times 3.61 \times 10^{-3} = 1.13 \Omega$$

$$K = 1/3.6, R_2' = R_2/K^2 = (3.6)^2 \times 0.1 = 1.3 \Omega$$

$$X_2 = 2\pi \times 50 \times 3.61 \times 10^{-3} = 1.13 \Omega; X_2' = (3.6)^2 \times 1.13 = 14.7 \Omega$$

$$I_{st} = \frac{V}{(R_2')^2 + (X_2')^2} \cdot \frac{3000/\sqrt{3}}{\sqrt{(1.3)^2 + (14.7)^2}} = 117.4 \text{ A}$$

Now,  $N_s = 120 \times 50/6 = 1000 \text{ rpm} = (50/3) \text{ rps}$

$$T_{st} = \frac{3}{2\pi N_s} \cdot \frac{V^2 R_2'}{(R_2')^2 + (X_2')^2} = \frac{3}{2\pi (50/3)} \times \frac{(3000/\sqrt{3})^2 \times 1.3}{(1.3^2 + 14.7^2)} = 513 \text{ N-m}$$

### Tutorial Problem No. 34.1

- In the case of an 8-pole induction motor, the supply frequency was 50-Hz and the shaft speed was 735 r.p.m. What were the magnitudes of the following: **(Nagpur Univ., Summer 2000)**
  - synchronous speed
  - speed of slip
  - per unit slip
  - percentage slip

**[750 r.p.m. ; 15 r.p.m.; 0.02 ; 2%]**
- A 6-pole, 50-Hz squirrel-cage induction motor runs on load at a shaft speed of 970 r.p.m. Calculate:-
  - the percentage slip
  - the frequency of induced current in the rotor.

**[3% ; 1.5 Hz]**
- An 8-pole alternator runs at 750. r.p.m. and supplies power to a 6-pole induction motor which has at full-load a slip of 3%. Find the full-load speed of the induction motor and the frequency of its rotor e.m.f. **[970 r.p.m. ; 1.5 Hz]**
- A 3-phase, 50-Hz induction motor with its rotor star-connected gives 500 V (r.m.s.) at standstill between the slip-rings on open-circuit. Calculate the current and power factor at standstill when the rotor winding is joined to a star-connected external circuit, each phase of which has a resistance of 10  $\Omega$  and an inductance of 0.04 H. The resistance per phase of the rotor winding is 0.2  $\Omega$  and its inductance is 0.04 H.  
Also, calculate the current and power factor when the slip-rings are short-circuited and the motor is running with a slip of 5 per cent. Assume the flux to remain constant. **[10.67 A; 0.376; 21.95 A; 0.303]**
- Obtain an expression for the condition of maximum torque of an induction motor. Sketch the torque-slip curves for several values of rotor circuit resistance and indicate the condition for maximum torque to be obtained at starting.  
If the motor has a rotor resistance of 0.02  $\Omega$  and a standstill reactance of 0.1  $\Omega$ , what must be the value of the total resistance of a starter for the rotor circuit for maximum torque to be exerted at starting? **[0.08  $\Omega$ ] (City and Guilds, London)**
- The rotor of a 6-pole, 50-Hz induction motor is rotated by some means at 1000 r.p.m. Compute (i) rotor voltage (ii) rotor frequency (iii) rotor slip and (iv) torque developed. Can the rotor rotate at this speed by itself? **[(i) 0 (ii) 0 (iii) 0 (iv) 0; No] (Elect. Engg. Grad I.E.T.E. June 1985)**
- The rotor resistances per phase of a 4-pole, 50-Hz, 3-phase induction motor are 0.024 ohm and 0.12 ohm respectively. Find the speed at maximum torque. Also find the value of the additional rotor resistance per phase required to develop 80% of maximum torque at starting. **[1200 r.p.m. 0.036  $\Omega$ ] (Elect. Machines, A.M.I.E. Sec. B, 1990)**
- The resistance and reactance per phase of the rotor of a 3-phase induction motor are 0.6 ohm and 5 ohms respectively. The induction motor has a star-connected rotor and when the stator is connected to a supply of normal voltage, the induced e.m.f. between the slip rings at standstill is 80 V. Calculate the current in each phase and the power factor at starting when (i) the slip-rings are shorted, (ii) slip-rings are connected to a star-connected resistance of 4 ohm per phase. **[(i) 9.17 amp, 0.1194 lag (ii) 6.8 amp, 0.6765 lag] [Rajiv Gandhi Technical University, Bhopal, 2000]**

### 34.18. Rotor E.M.F. and Reactance Under Running Conditions

Let  $E_2 =$  **standstill** rotor induced e.m.f./phase  
 $X_2 =$  **standstill** rotor reactance/phase,  $f_2 =$  rotor current frequency at **standstill**

When rotor is stationary i.e.  $s = 1$ , the frequency of rotor e.m.f. is the same as that of the stator supply frequency. The value of e.m.f. induced in the rotor at standstill is maximum because the relative speed between the rotor and the revolving stator flux is maximum. In fact, the motor is equivalent to a 3-phase transformer with a short-circuited rotating secondary.

When rotor starts running, the relative speed between it and the rotating stator flux is decreased. Hence, the rotor induced e.m.f. which is directly proportional to this relative speed, is also decreased (and may disappear altogether if rotor speed were to become equal to the speed of stator flux). Hence, for a slip  $s$ , the rotor induced e.m.f. will be  $s$  times the induced e.m.f. at standstill.

Therefore, under **running conditions**  $E_r = sE_2$

The frequency of the induced e.m.f. will likewise become  $f_r = sf_2$

Due to decrease in frequency of the rotor e.m.f., the rotor reactance will also decrease.

$$\therefore X_r = sX_2$$

where  $E_r$  and  $X_r$  are rotor e.m.f. and reactance under **running** conditions.

### 34.19. Torque Under Running Conditions

$$T \propto E_r I_r \cos \phi_2 \text{ or } T \propto \phi I_r \cos \phi_2 \quad (\because E_r \propto \phi)$$

where  $E_r =$  rotor e.m.f./phase under **running conditions**  
 $I_r =$  rotor current/phase under **running conditions**

Now  $E_r = sE_2$

$$\therefore I_r = \frac{E_r}{Z_r} = \frac{sE_2}{\sqrt{[R_2^2 + (sX_2)^2]}}$$

$$\cos \phi_2 = \frac{R_2}{\sqrt{[R_2^2 + (sX_2)^2]}} \quad \text{—Fig. 34.20}$$

$$\therefore T \propto \frac{s \Phi E_2 R_2}{R_2^2 + (sX_2)^2} = \frac{k \Phi \cdot s \cdot E_2 R_2}{R_2^2 + (sX_2)^2}$$

Also  $T = \frac{k_1 \cdot s E_2^2 R_2}{R_2^2 + (sX_2)^2} \quad (\because E_2 \propto \phi)$

Fig. 34.20

where  $k_1$  is another constant. Its value can be proved to be equal to  $3/2 \pi N_s$  (Art. 34.38). Hence, in that case, expression for torque becomes

$$T = \frac{3}{2\pi N_s} \cdot \frac{sE_2^2 R_2}{R_2^2 + (sX_2)^2} = \frac{3}{2\pi N_s} \cdot \frac{sE_2^2 R_2}{Z_r^2}$$

At standstill when  $s = 1$ , obviously

$$T_{st} = \frac{k_1 E_2^2 R_2}{R_2^2 + X_2^2} \left( \text{or } = \frac{3}{2\pi N_s} \cdot \frac{E_2^2 R_2}{R_2^2 + X_2^2} \right) \text{ the same as in Art. 34.13.}$$

**Example 34.10.** The star connected rotor of an induction motor has a standstill impedance of  $(0.4 + j4)$  ohm per phase and the rheostat impedance per phase is  $(6 + j2)$  ohm.

The motor has an induced emf of 80 V between slip-rings at standstill when connected to its normal supply voltage. Find

- (i) rotor current at standstill with the rheostat is in the circuit.
- (ii) when the slip-rings are short-circuited and motor is running with a slip of 3%.

(Elect. Engg. I, Nagpur Univ. 1993)

**Solution. (1) Standstill Conditions**

Voltage/rotor phase =  $80/\sqrt{3} = 46.2$  V; rotor and starter impedance/phase =  $(6.4 + j6) = 8.77 \angle 43.15^\circ$   
 Rotor current/phase =  $46.2/8.77 = 5.27$  A (p.f. =  $\cos 43.15^\circ = 0.729$ )

**(2) Running Conditions.** Here, starter impedance is cut out.

Rotor voltage/phase,  $E_r = sE_2 = 0.03 \times 46.2 = 1.386$  V  
 Rotor reactance/phase,  $X_r = 0.03 \times 4 = 0.12 \Omega$   
 Rotor impedance/phase,  $Z_r = 0.4 + j0.12 = 0.4176 \angle 16.7^\circ$   
 Rotor current/phase =  $1.386/0.4176 = 3.32$  A (p.f. =  $\cos 16.7^\circ = 0.96$ )

**Note.** It has been assumed that flux across the air-gap remains constant

**34.20. Condition for Maximum Torque Under Running Conditions**

The torque of a rotor under **running** conditions is

$$T = \frac{k\Phi s E_2 R_2}{R_2^2 + (sX_2)^2} = k_1 \frac{s E_2^2 R_2}{R_2^2 + (sX_2)^2} \quad \dots (i)$$

The condition for maximum torque may be obtained by differentiating the above expression with respect to slip  $s$  and then putting it equal to zero. However, it is simpler to put  $Y = \frac{1}{T}$  and then differentiate it.

$$\therefore Y = \frac{R_2^2 + (sX_2)^2}{k\Phi s E_2 R_2} = \frac{R_2}{k\Phi s E_2} + \frac{sX_2^2}{k\Phi E_2 R_2}; \frac{dY}{ds} = \frac{-R_2}{k\Phi s^2 E_2} + \frac{X_2^2}{k\Phi E_2 R_2} = 0$$

$$\therefore \frac{R_2}{k\Phi s^2 E_2} = \frac{X_2^2}{k\Phi E_2 R_2} \quad \text{or} \quad R_2^2 = s^2 X_2^2 \quad \text{or} \quad R_2 = sX_2$$

Hence, torque under **running condition** is maximum at that value of the slip  $s$  which makes rotor reactance per phase equal to rotor resistance per phase. This slip is sometimes written as  $s_b$  and the maximum torque as  $T_b$ .

Slip corresponding to maximum torque is  $s = R_2/X_2$

Putting  $R_2 = sX_2$  in the above equation for the torque, we get

$$T_{\max} = \frac{k\Phi s^2 E_2 X_2}{2 s^2 X_2^2} \left( \text{or} \frac{k\Phi s E_2 R_2}{2 R_2^2} \right) \quad \text{or} \quad T_{\max} = \frac{k\Phi E_2}{2 X_2} \left( \text{or} \frac{k\Phi s E_2}{2 R_2} \right) \quad \dots (ii)$$

Substituting value of  $s = R_2/X_2$  in the other equation given in (i) above, we get

$$T_{\max} = k_1 \frac{(R_2 / X_2) \cdot E_2^2 \cdot R_2}{R_2^2 + (R_2 / X_2)^2 \cdot X_2^2} = k_1 \frac{E_2^2}{2 X_2}$$

Since,  $k_1 = 3/2\pi N_s$ , we have  $T_{\max} = \frac{3}{2\pi N_s} \cdot \frac{E_2^2}{2 X_2}$  N-m

From the above, it is found

1. that the maximum torque is independent of rotor resistance as such.
2. however, the speed or slip at which maximum torque occurs is determined by the rotor

resistance. As seen from above, torque becomes maximum when rotor reactance equals its resistance. Hence, by varying rotor resistance (possible only with slip-ring motors) maximum torque can be made to occur at any desired slip (or motor speed).

3. maximum torque varies inversely as standstill reactance. Hence, it should be kept as small as possible.
4. maximum torque varies directly as the square of the applied voltage.
5. for obtaining maximum torque at starting ( $s = 1$ ), rotor resistance must be equal to rotor reactance.

**Example 34.11.** A 3-phase, slip-ring, induction motor with star-connected rotor has an induced e.m.f. of 120 volts between slip-rings at standstill with normal voltage applied to the stator. The rotor winding has a resistance per phase of 0.3 ohm and standstill leakage reactance per phase of 1.5 ohm.

Calculate (i) rotor current/phase when running short-circuited with 4 percent slip and (ii) the slip and rotor current per phase when the rotor is developing maximum torque.

(Elect. Engg.-II, Pune Univ. 1989)

**Solution.** (i) induced e.m.f./rotor phase,  $E_r = sE_2 = 0.04 \times (120/\sqrt{3}) = 2.77\text{V}$

rotor reactance/phase,  $X_r = sX_2 = 0.04 \times 1.5 = 0.06 \Omega$

rotor impedance/phase  $= \sqrt{0.3^2 + 0.06^2} = 0.306 \Omega$

rotor current/phase  $= 2.77/0.306 = 9\text{A}$

(ii) For developing maximum torque,

$$R_2 = sX_2 \quad \text{or} \quad s = R_2/X_2 = 0.3/1.5 = 0.2$$

$$X_r = 0.2 \times 1.5 = 0.3 \Omega, Z_r = \sqrt{0.3^2 + 0.3^2} = 0.42 \Omega$$

$$E_r = sE_2 = 0.2 \times (120/\sqrt{3}) = 13.86 \text{ V}$$

$$\therefore \text{Rotor current/phase} = 13.86/0.42 = 33\text{A}$$

### 34.21. Rotor Torque and Breakdown Torque

The rotor torque at any slip  $s$  can be expressed in terms of the maximum (or breakdown) torque  $T_b$  by the following equation

$$T = T_b \left[ \frac{2}{(s_b/s) + (s/s_b)} \right] \quad \text{where } s_b \text{ is the breakdown or pull-out slip.}$$

**Example 34.12.** Calculate the torque exerted by an 8-pole, 50-Hz, 3-phase induction motor operating with a 4 per cent slip which develops a maximum torque of 150 kg-m at a speed of 660 r.p.m. The resistance per phase of the rotor is 0.5  $\Omega$ . (Elect. Machines, A.M.I.E. Sec. B, 1989)

**Solution.**  $N_s = 120 \times 50/8 = 750 \text{ r.p.m.}$

Speed at maximum torque  $= 660 \text{ r.p.m.}$  Corresponding slip  $s_b = \frac{750 - 660}{750} = 0.12$

For maximum torque,  $R_2 = s_b X_2$

$$\therefore X_2 = R_2/s_b = 0.5/0.12 = 4.167 \Omega$$

As seen from Eq. (ii) of Art. 34.20,

$$T_{\max} = k \Phi E_2 \cdot \frac{s_b}{2R_2} = k \Phi E_2 \cdot \frac{0.12}{2 \times 0.5} = 0.12 k \Phi E_2 \quad \dots (i)$$

**When slip is 4 per cent**

As seen from Eq. (i) of Art. 34.20

$$T = k \Phi E_2 \frac{sR_2}{R_2^2 + (sX_2)^2} = k \Phi E_2 \frac{0.04 \times 0.5}{0.5^2 + (0.04 \times 4.167)^2} = \frac{0.02 k \Phi E_2}{0.2778}$$

$$\therefore \frac{T}{T_{\max}} = \frac{T}{150} = \frac{0.02}{0.2778 \times 0.12} \quad \therefore T = 90 \text{ kg-m}$$

**Alternative Solution**

$$T_b = 150 \text{ kg.m; } s_b = 0.12, s = 4\% = 0.04, T = ?$$

$$T = T_b \left( \frac{2}{(s_b/s) + (s/s_b)} \right) \quad \dots \text{Art 34.21}$$

$$= 150 \left( \frac{2}{(0.12/0.04) + (0.04/0.12)} \right) = 90 \text{ kg-m}$$

**34.22. Relation Between Torque and Slip**

A family of torque/slip curves is shown in Fig. 34.21 for a range of  $s = 0$  to  $s = 1$  with  $R_2$  as the parameter. We have seen above in Art. 34.19 that

$$T = \frac{k \Phi s E_2 R_2}{R_2^2 + (sX_2)^2}$$

It is clear that when  $s = 0, T = 0$ , hence the curve starts from point  $O$ .

At normal speeds, close to synchronism, the term  $(sX_2)$  is small and hence negligible w.r.t.  $R_2$ .

$$\therefore T \propto \frac{s}{R_2}$$

or  $T \propto s$  if  $R_2$  is constant.

Hence, for low values of slip, the torque/slip curve is approximately a straight line. As slip increases (for increasing load on the motor), the torque also increases and becomes maximum when  $s = R_2/X_2$ . This torque is known as 'pull-out' or 'breakdown' torque  $T_b$  or stalling torque. As the slip further increases (*i.e.* motor speed falls) with further increase in motor load, then  $R_2$  becomes negligible as compared to  $(sX_2)$ . Therefore, for large values of slip

$$T \propto \frac{s}{(sX_2)^2} \propto \frac{1}{s}$$

Fig. 34.21

Hence, the torque/slip curve is a rectangular hyperbola. So, we see that beyond the point of maximum torque, any further increase in motor load results in decrease of torque developed by the motor. The result is that the motor slows down and eventually stops. The circuit-breakers will be tripped open if the circuit has been so protected. In fact, the stable operation of the motor lies between the values of  $s = 0$  and that corresponding to maximum torque. The operating range is shown shaded in Fig. 34.21.

It is seen that although maximum torque does not depend on  $R_2$ , yet the exact location of  $T_{\max}$  is dependent on it. Greater the  $R_2$ , greater is the value of slip at which the maximum torque occurs.

### 34.23. Effect of Change in Supply Voltage on Torque and Speed

As seen from Art. 34.19,  $T = \frac{k\Phi sE_2R_2}{R_2^2 + (sX_2)^2}$

As  $E_2 \propto \phi \propto V$  where  $V$  is supply voltage  $\therefore T \propto sV^2$

Obviously, torque at any speed is proportional to the square of the applied voltage. If stator voltage decreases by 10%, the torque decreases by 20%. Changes in supply voltage not only affect the starting torque  $T_{st}$  but torque under running conditions also. If  $V$  decreases, then  $T$  also decreases. Hence, for maintaining the same torque, slip increases *i.e.* speed falls.

Let  $V$  change to  $V'$ ,  $s$  to  $s'$  and  $T$  to  $T'$ ; then  $\frac{T}{T'} = \frac{sV^2}{s'V'^2}$

### 34.24. Effect of Changes in supply Frequency on Torque and Speed

Hardly any important changes in frequency take place on a large distribution system except during a major disturbance. However, large frequency changes often take place on isolated, low-power systems in which electric energy is generated by means of diesel engines or gas turbines. Examples of such systems are : emergency supply in a hospital and the electrical system on a ship etc.

The major effect of change in supply frequency is on motor **speed**. If frequency drops by 10%, then motor speed also drops by 10%. Machine tools and other motor-driven equipment meant for 50 Hz causes problem when connected to 60-Hz supply. Everything runs  $(60 - 50) \times 100/50 = 20\%$  faster than normal and this may not be acceptable in all applications. In that case, we have to use either gears to reduce motor speed or an expensive 50-Hz source.

A 50-Hz motor operates well on a 60-Hz line provided its terminal voltage is raised to  $60/50 = 6/5$  (*i.e.* 120%) of the name-plate rating. In that case, the new breakdown torque becomes equal to the original breakdown torque and the starting torque is only slightly reduced. However, power factor, efficiency and temperature rise remain satisfactory.

Similarly, a 60-Hz motor can operate satisfactorily on 50-Hz supply provided its terminal voltage is reduced to  $5/6$  (*i.e.* 80%) of its name-plate rating.

### 34.25. Full-load Torque and Maximum Torque

Let  $s_f$  be the slip corresponding to full-load torque, then

$$T_f \propto \frac{s_f R_2}{R_2^2 + (s_f X_2)^2} \quad \text{and} \quad T_{\max} \propto \frac{1}{2 \times X_2} \quad \dots \text{Art 34.20}$$

$$\therefore \frac{T_f}{T_{\max}} = \frac{2s_f R_2 X_2}{R_2^2 + (s_f X_2)^2}$$

Dividing both the numerator and the denominator by  $X_2^2$ , we get

$$\frac{T_f}{T_{\max}} = \frac{2s_f \cdot R_2 / X_2}{(R_2 / X_2)^2 + s_f^2} = \frac{2as_f}{a^2 + s_f^2}$$

where  $a = R_2/X_2 = \text{resistance/standstill reactance}^*$

---

\* In fact  $a = s_m$ —slip corresponding to maximum torque. In that case, the relation becomes

$$\frac{T_f}{T_{\max}} = \frac{2s_m s_f^2}{s_m^2 + s_f^2} \quad \text{— where } s_f = \text{full-load slip.}$$

In general, 
$$\frac{\text{operating torque at any slip } s}{\text{maximum torque}} = \frac{2as}{a^2 + s^2}$$

**34.26. Starting Torque and Maximum Torque**

$$T_{st} \propto \frac{R_2}{R_2^2 + X_2^2} \quad \dots \text{Art 34.13}$$

$$T_{max} \propto \frac{1}{2X_2} \quad \dots \text{Art. 34.20}$$

$$\therefore \frac{T_{st}}{T_{max}} = \frac{2R_2X_2}{R_2^2 + X_2^2} = \frac{2R_2/X_2}{1 + (R_2/X_2)^2} = \frac{2a}{1 + a^2}$$

where 
$$a = \frac{R_2}{X_2} = \frac{\text{rotor resistance}}{\text{stand still reactance}} \text{ per phase*}$$

**Example. 34.13(a).** A 3- $\phi$  induction motor is driving full-load torque which is independent of speed. If line voltage drops to 90% of the rated value, find the increase in motor copper losses.

**Solution.** As seen from Art. 34.23, when  $T$  remains constant,  $s_1 V_1^2 = s_2 V_2^2$

$$\therefore \frac{s_2}{s_1} = \left(\frac{V_1}{V_2}\right)^2 = \left(\frac{1}{0.9}\right)^2 = 1.23$$

Again from Art. 34-19,  $I_2 \propto sV \therefore \frac{I_2'}{I_2} = \frac{s_2 V_2}{s_1 V_1} = 1.2 \times 0.9 = 1.107$

Now, Cu losses are nearly proportional to  $I_2^2$

$$\therefore \frac{\text{Cu loss in the 2nd case}}{\text{Cu loss in the 1st case}} = \frac{(I_2')^2}{I_2^2} = 1.107^2 = 1.23$$

Thus a reduction of 10% in line voltage causes about 23% increase in Cu losses.

**Example. 34.13 (b).** A 230-V, 6-pole, 3- $\phi$ , 50-Hz, 15-kW induction motor drives a constant torque load at rated frequency, rated voltage and rated kW output and has a speed of 980 rpm and an efficiency of 93%. Calculate (i) the new operating speed if there is a 10% drop in voltage and 5% drop in frequency and (ii) the new output power. Assume all losses to remain constant.

**Solution. (i)**  $V_2 = 0.9 \times 230 = 207$  V;  $f_2 = 0.95 \times 50 = 47.5$  Hz;  $N_{s1} = 120 \times 50/6 = 1000$  rpm;  $N_{s2} = 120 \times 47.5/6 = 950$  rpm;  $s_1 = (1000 - 980)/1000 = 0.02$

Since the load torque remains constant, the product  $(sV^2/f)$  remains constant.

$$\therefore s_1 V_1^2 / f_1 = \frac{s_2 V_2^2}{f_2} \text{ or } s_2 = s_1 \left(\frac{V_1}{V_2}\right)^2 \cdot f_2 / f_1 = 0.02 (230/207)^2 \times 47.5/50 = 0.2234$$

$$\therefore N_2 = N_{s2} (1 - s_2) = 950 (1 - 0.0234) = 928 \text{ rpm}$$

**(ii)**  $P \propto TN$ . Since torque remains constant,  $P \propto N$

$$\therefore P_1 \propto N_1; P_2 \propto N_2; \text{ or } P_2 = P_1 \times N_2 / N_1 = 15 \times 928 / 980 = \mathbf{14.2 \text{ kW}}$$

---

\* Similarly, the relation becomes 
$$\frac{T_f}{T_{max}} = \frac{2s_m}{1 + s_m^2}$$

**Example 34.14 (a).** A 3-phase, 400/200-V, Y-Y connected wound-rotor induction motor has  $0.06\Omega$  rotor resistance and  $0.3\Omega$  standstill reactance per phase. Find the additional resistance required in the rotor circuit to make the starting torque equal to the maximum torque of the motor.

(Electrical Technology, Bombay Univ. 1990)

**Solution.**

$$\frac{T_{st}}{T_{max}} = \frac{2a}{1+a^2}; \text{ Since } T_{st} = T_{max}$$

$$\therefore 1 = \frac{2a}{1+a^2} \text{ or } a = 1 \text{ Now, } a = \frac{R_2 + r}{X_2}$$

where  $r =$  external resistance per phase added to the rotor circuit

$$\therefore 1 = \frac{0.06 + r}{0.3} \therefore r = 0.3 - 0.06 = \mathbf{0.24\Omega}$$

**Example 34.14 (b).** 3-phase, 50-Hz, 8-pole, induction motor has full-load slip of 2%. The rotor-resistance and stand still rotor-reactance per phase are 0.001 ohm and 0.005 ohm respectively. Find the ratio of the maximum to full-load torque and the speed at which the maximum torque occurs.

(Amravati University, 1999)

**Solution.** Synchronous speed,  $N_s = 120 \times 50 / 8 = 750$  rpm  
 Slip at maximum torque,  $s_{mT} = r_2/x_2$

Thus, let a  $= \frac{r_2}{x_2} = \frac{0.001}{0.005} = 0.2$

Corresponding speed  $= (1 - 0.2) \times 750 = 600$  rpm

$$\frac{\text{Full-load torque}}{\text{Maximum torque}} = \frac{2 s_{mT} s_{fL}^2}{s_{mT}^2 + s_{fL}^2} \therefore \frac{T_{fL}}{T_{max}} = \frac{2 \times 0.2 \times 0.02^2}{0.20^2 + 0.02^2} = \frac{1.6 \times 10^{-4}}{0.0404}$$

$$\therefore \frac{T_{max}}{T_f} = 252.5$$

$$= \mathbf{3.96 \times 10^{-3}}$$

**Example 34.14 (c).** A 12-pole, 3-phase, 600-V, 50-Hz, star-connected, induction motor has rotor-resistance and stand-still reactance of 0.03 and 0.5 ohm per phase respectively. Calculate:

(a) Speed of maximum torque. (b) ratio of full-load torque to maximum torque, if the full-load speed is 495 rpm.

(Nagpur University, April 1999)

**Solution.** For a 12-pole, 50 Hz motor,  
 Synchronous speed  $= 120 \times 50 / 12 = 500$  rpm  
 For  $r = 0.03$  and  $x = 0.5$  ohm, the slip for maximum torque is related as :

$$s_{mT} = a = r/x = 0.03/0.5 = 0.06$$

(a) Corresponding speed  $= 500 (1 - s_{mT}) = 470$  rpm  
 (b) Full-load speed  $= 495$  rpm, slip  $s = 0.01$ , at full load.

$$\frac{\text{Full-load torque}}{\text{Maximum torque}} = \frac{2 as}{a^2 + s^2} = \frac{2 \times 0.06 \times 0.01}{0.06^2 + 0.01^2} = \mathbf{0.324}$$

**Example 34.15.** A 746-kW, 3-phase, 50-Hz, 16-pole induction motor has a rotor impedance of  $(0.02 + j 0.15) \Omega$  at standstill. Full-load torque is obtained at 360 rpm. Calculate (i) the ratio of maximum to full-load torque (ii) the speed of maximum torque and (iii) the rotor resistance to be added to get maximum starting torque.

(Elect. Machines, Nagpur Univ. 1993)

**Solution.** Let us first find out the value of full-load slip  $s_f$

$$N_s = 120 \times 50 / 16 = 375 \text{ rpm.}; \text{ F.L. Speed} = 360 \text{ rpm.}$$

$$s_f = (375 - 360) / 375 = 0.04; a = R_2/X_2 = 0.02/0.15 = 2/15$$

$$(i) \quad \frac{T_f}{T_{\max}} = \frac{2as_f}{a^2 + s_f^2} = \frac{2 \times (2/15) \times 0.04}{(2/15)^2 + (0.04)^2} = 0.55 \text{ or } \frac{T_{\max}}{T_f} = \frac{1}{0.55} = \mathbf{1.818}$$

$$(ii) \text{ At maximum torque, } a = s_m = R_2/X_2 = 0.02/0.15 = 2/15$$

$$N = N_s(1 - s) = 375(1 - 2/15) = \mathbf{325 \text{ r.p.m.}}$$

$$(iii) \text{ For maximum starting torque, } R_2 = X_2. \text{ Hence, total rotor resistance per phase} = \mathbf{0.15\Omega}$$

$$\therefore \text{ external resistance required/phase} = 0.15 - 0.02 = \mathbf{0.13\Omega}$$

**Example 34.16.** The rotor resistance and reactance per phase of a 4-pole, 50-Hz, 3-phase induction motor are 0.025 ohm and 0.12 ohm respectively. Make simplifying assumptions, state them and :

(i) find speed at maximum torque

(ii) find value of additional rotor resistance per phase required to give three-fourth of maximum torque at starting. Draw the equivalent circuit of a single-phase induction motor.

(Elect. Machines, Nagpur Univ. 1993)

**Solution.** (i) At maximum torque,  $s = R_2/X_2 = 0.025/0.12 = 0.208$ .

$$N_s = 120 \times 50/4 = 1500 \text{ rpm} \quad \therefore N = 1500(1 - 0.208) = \mathbf{1188 \text{ rpm}}$$

$$(ii) \text{ It is given that } T_{st} = 0.75 T_{\max} \quad \text{Now, } \frac{T_{st}}{T_{\max}} = \frac{2a}{1 + a^2} = \frac{3}{4}$$

$$\therefore 3a^2 - 8a + 3 = 0; \quad a = \frac{8 \pm \sqrt{64 - 36}}{6} = 0.45 \Omega^*$$

Let,

$r$  = additional rotor resistance reqd., then

$$a = \frac{R_2 + r}{R_2} \quad \text{or} \quad 0.45 = \frac{0.025 + r}{0.12} \quad \therefore r = \mathbf{0.029\Omega}$$

**Example 34.17.** A 50-Hz, 8-pole induction motor has F.L. slip of 4%. The rotor resistance/phase = 0.01 ohm and standstill reactance/phase = 0.1 ohm. Find the ratio of maximum to full-load torque and the speed at which the maximum torque occurs.

$$\text{Solution.} \quad \frac{T_f}{T_{\max}} = \frac{2as_f}{a^2 + s_f^2}$$

$$\text{Now,} \quad a = R_2/X_2 = 0.01/0.1 = 0.1, \quad s_f = 0.04$$

$$\therefore \quad \frac{T_f}{T_{\max}} = \frac{2 \times 0.1 \times 0.04}{0.1^2 + 0.04^2} = \frac{0.008}{0.0116} = 0.69 \quad \therefore \frac{T_{\max}}{T_f} = \frac{1}{0.69} = \mathbf{1.45}$$

$$N_s = 120 \times 50/8 = 750 \text{ rpm, } s_m = 0.1$$

$$N = (1 - 0.1) \times 750 = 675 \text{ rpm}$$

**Example 34.18.** For a 3-phase slip-ring induction motor, the maximum torque is 2.5 times the full-load torque and the starting torque is 1.5 times the full-load torque. Determine the percentage reduction in rotor circuit resistance to get a full-load slip of 3%. Neglect stator impedance.

(Elect. Machines, A.M.I.E. Sec. B, 1992)

**Solution.** Given,  $T_{\max} = 2.5 T_f$ ;  $T_{st} = 1.5 T_f$ ;  $T_{st}/T_{\max} = 1.5/2.5 = 3/5$ .

\* The larger value of 2.214  $\Omega$  has been rejected.

Now, 
$$\frac{T_{st}}{T_f} = \frac{3}{5} = \frac{2a}{1+a^2} \quad \text{or} \quad 3a^2 - 10a + 3 = 0 \quad \text{or} \quad a = 1/3$$

Now, 
$$a = R_2/X_2 \text{ or } R_2 = X_2/3$$

When F.L. slip is 0.03

$$\frac{T_f}{T_{st}} = \frac{2as}{a^2 + s^2} \quad \text{or} \quad \frac{2}{2.5} = \frac{2a \times 0.03}{a^2 + 0.03^2}$$

$$a^2 - 0.15a + 0.009 = 0 \quad \text{or} \quad a = 0.1437$$

If  $R'_2$  is the new rotor circuit resistance, then  $0.1437 = R'_2/X_2$  or  $R'_2 = 0.1437 X_2$

% reduction in rotor resistance is

$$= \frac{(X_2/3) - 0.1437 \times X_2}{(X_2/3)} \times 100 = \mathbf{56.8\%}$$

**Example 34.19.** An 8-pole, 50-Hz, 3-phase slip-ring induction motor has effective rotor resistance of 0.08 Ω/phase. Stalling speed is 650 r.p.m. How much resistance must be inserted in the rotor phase to obtain the maximum torque at starting? Ignore the magnetising current and stator leakage impedance. (Elect. Machines-I, Punjab Univ. 1991)

**Solution.** It should be noted that stalling speed corresponds to maximum torque (also called stalling torque) and to maximum slip **under running conditions**.

$$N_s = 120 \times 50/8 = 750 \text{ r.p.m.}; \text{ stalling speed is } = 650 \text{ r.p.m.}$$

$$s_b = (750 - 650)/750 = 2/15 = 0.1333 \text{ or } 13.33\%$$

Now, 
$$s_b = R_2/X_2 \quad \therefore \quad X_2 = 0.08 \times 15/2 = 0.6 \Omega$$

$$\frac{T_{st}}{T_{max}} = \frac{2a}{1+a^2}. \text{ Since } T_{st} = T_{max} \quad \therefore \quad 1 = \frac{2a}{1+a^2} \text{ or } a = 1$$

Let  $r$  be the external resistance per phase added to the rotor circuit. Then

$$a = \frac{R_2 + r}{X_2} \quad \text{or} \quad 1 = \frac{0.08 + r}{0.6} \quad \therefore \quad \mathbf{r = 0.52 \Omega \text{ per phase.}}$$

**Example 34.20.** A 4-pole, 50-Hz, 3-φ induction motor develops a maximum torque of 162.8 N-m at 1365 r.p.m. The resistance of the star-connected rotor is 0.2 Ω/phase. Calculate the value of the resistance that must be inserted in series with each rotor phase to produce a starting torque equal to half the maximum torque.

**Solution.** 
$$N_s = 120 \times 50/4 = 1500 \text{ r.p.m. } N = 1365 \text{ r.p.m.}$$

∴ Slip corresponding to maximum torque is

$$s_b = (1500 - 1365)/1500 = 0.09 \quad \text{But } s_b = R_2/X_2 \quad \therefore \quad X_2 = 0.2/0.09 = 2.22 \Omega$$

Now, 
$$T_{max} = \frac{k \Phi E_2}{2 X_2} = \frac{K}{2 X_2} \quad (\text{where } K = k \Phi E_2) \quad \dots \text{Art 34.20}$$

$$= \frac{K}{2 \times 2.22} = 0.225 K$$

Let ' $r$ ' be the external resistance introduced per phase in the rotor circuit, then

Starting torque 
$$T_{st} = \frac{k \Phi E_2 (R_2 + r)}{(R_2 + r)^2 + (X_2)^2} = \frac{K (0.2 + r)}{(0.2 + r)^2 + (0.2/0.09)^2}$$

∴ 
$$T_{st} = \frac{1}{2} \cdot T_{max} \quad \therefore \quad \frac{K (0.2 + r)}{(0.2 + r)^2 + (2.22)^2} = \frac{0.225 K}{2}$$

Solving the quadratic equation for ' $r$ ', we get  $r = \mathbf{0.4 \Omega}$

**Example 34.21.** A 4-pole, 50-Hz, 7.46.kW motor has, at rated voltage and frequency, a starting torque of 160 per cent and a maximum torque of 200 per cent of full-load torque. Determine (i) full-load speed (ii) speed at maximum torque. **(Electrical Technology-I, Osmania Univ. 1990)**

**Solution.**  $\frac{T_{st}}{T_f} = 1.6$  and  $\frac{T_{max}}{T_f} = 2 \quad \therefore \frac{T_{st}}{T_{max}} = \frac{1.6}{2} = 0.8$

Now,  $\frac{T_{st}}{T_{max}} = \frac{2a}{1+a^2} \quad \therefore \frac{2a}{1+a^2} = 0.8$

or  $0.8a^2 - 2a + 0.8 = 0 \quad a = 0.04 \quad \therefore a = R_2/X_2 = 0.04$  or  $R_2 = 0.04X_2$

Also,  $\frac{T_f}{T_{max}} = \frac{2as_f}{a^2 + s_f^2} = \frac{1}{2}$  or  $\frac{2 \times 0.04 s_f}{0.0016 + s_f^2} = \frac{1}{2}$  or  $s_f = 0.01$

(i) full-load speed occurs at a slip of 0.01 or 1 per cent. Now,

$$N_s = 120 \times 50/4 = 1500 \text{ r.p.m.}; N = 1500 - 15 = \mathbf{1485 \text{ r.p.m.}}$$

(ii) Maximum torque occurs at a slip given by  $s_b = R_2/X_2$ . As seen from above slip corresponding to maximum torque is 0.04.

$$\therefore N = 1500 - 1500 \times 0.04 = \mathbf{1440 \text{ r.p.m.}}$$

**Example 34.22.** A 3-phase induction motor having a 6-pole, star-connected stator winding runs on 240-V, 50-Hz supply. The rotor resistance and standstill reactance are 0.12 ohm and 0.85 ohm per phase. The ratio of stator to rotor turns is 1.8. Full load slip is 4%.

Calculate the developed torque at full load, maximum torque and speed at maximum torque.

**(Elect. Machines, Nagpur Univ. 1993)**

**Solution.** Here,  $K = \frac{\text{rotor turns/phase}}{\text{stator turns/phase}} = \frac{1}{1.8}$

$$E_2 = KE_1 = \frac{1}{1.8} \times \frac{240}{\sqrt{3}} = 77 \text{ V}; s = 0.04;$$

$$N_s = 120 \times 50/6 = 1000 \text{ rpm} = 50/3 \text{ rps}$$

$$T_f = \frac{3}{2\pi N_s} \cdot \frac{sE_2^2 R_2}{R_2^2 + (sX_2)^2} \quad \dots \text{Art. 34.19}$$

$$= \frac{3}{2\pi (50/3)} \cdot \frac{0.04 \times 77^2 \times 0.12}{0.12^2 + (0.14 \times 0.85)^2} = 52.4 \text{ N-m}$$

For maximum torque,  $s = R_2/X_2 = 0.12/0.85 = 0.14$

$$\therefore T_{max} = \frac{3}{2\pi (50/3)} \cdot \frac{0.14 \times 77^2 \times 0.12}{0.12^2 + (0.14 \times 0.85)^2} = 99.9 \text{ N-m}$$

Alternatively, as seen from Art 34.20.

$$T_{max} = \frac{3}{2\pi N_s} \cdot \frac{E_2^2}{2 X_2}$$

$$\therefore T_{max} = \frac{3}{2\pi (50/3)} \cdot \frac{77^2}{2 \times 0.85} = 99.9 \text{ N-m}$$

Speed corresponding to maximum torque,  $N = 1000(1 - 0.14) = \mathbf{860 \text{ rpm}}$

**Example 34.23.** The rotor resistance and standstill reactance of a 3-phase induction motor are respectively 0.015  $\Omega$  and 0.09  $\Omega$  per phase. At normal voltage, the full-load slip is 3%. Estimate the percentage reduction in stator voltage to develop full-load torque at half full-load speed. Also, calculate the power factor. **(Adv. Elect. Machines, A.M.I.E. 1989)**

**Solution.** Let  $N_s = 100$  r.p.m. F.L. speed =  $(1 - 0.03)100 = 97$  r.p.m.

Let the normal voltage be  $V_1$  volts.

Speed in second case =  $97/2 = 48.5$  r.p.m.

$\therefore$  slip =  $(100 - 48.5)/100 = 0.515$  or 51.5%

Now, 
$$T = \frac{k \Phi s E_2 R_2}{R_2^2 + (s X_2)^2} = \frac{k s V^2 R_2}{R_2^2 + (s X_2)^2} \quad (\because E_2 \propto \Phi \propto V)$$

Since torque is the same in both cases,

$$\frac{k V_1^2 s_1 R_2}{R_2^2 + (s_1 X_2)^2} = \frac{k V_2^2 s_2 R_2}{R_2^2 + (s_2 X_2)^2} \quad \text{where } V_2 = \text{stator voltage in second case}$$

$$\begin{aligned} \therefore \left(\frac{V_1}{V_2}\right)^2 &= \frac{s_2}{s_1} \cdot \frac{R_2^2 + (s_1 X_2)^2}{R_2^2 + (s_2 X_2)^2} \\ &= \frac{51.3}{3} \cdot \frac{0.015^2 + (0.03 \times 0.09)^2}{0.015^2 + (0.515 \times 0.09)^2} = 1.68 \end{aligned}$$

$$\therefore \frac{V_1}{V_2} = \sqrt{1.68} = 1.296 \quad \text{or} \quad \frac{V_1 - V_2}{V_1} = \frac{0.296}{1.296}$$

Hence, percentage, reduction in stator (or supply voltage) is

$$= \frac{V_1 - V_2}{V_1} \times 100 = \frac{0.296 \times 100}{1.296} = \mathbf{22.84\%}$$

In the second case,  $\tan \phi = s_2 X_2 / R_2 = 0.515 \times 0.09 / 0.015 = 3.09$

$\therefore \phi = \tan^{-1}(3.09) = 72^\circ 4'$  and p.f. =  $\cos \phi = \cos 72^\circ 4' = \mathbf{0.31}$

### 34.27. Torque/Speed Curve

The torque developed by a conventional 3-phase motor depends on its speed but the relation between the two cannot be represented by a simple equation. It is easier to show the relationship in the form of a curve (Fig. 34.22). In this diagram,  $T$  represents the nominal full-load torque of the motor. As seen, the starting torque (at  $N=0$ ) is  $1.5 T$  and the maximum torque (also called breakdown torque) is  $2.5 T$ .

Fig. 34.22

At full-load, the motor runs at a speed of  $N$ . When mechanical load increases, motor speed decreases till the motor torque again becomes equal to the load torque. As long as the two torques are in balance, the motor will run at constant (but lower) speed. However, if the load torque exceeds  $2.5 T$ , the motor will suddenly stop.

### 34.28. Shape of Torque/Speed Curve

For a squirrel-cage induction motor (SCIM), shape of its torque/speed curve depends on the voltage and frequency applied to its stator. If  $f$  is fixed,  $T \propto V^2$  (Art 34.22). Also, synchronous speed

Fig. 34.23

depends on the supply frequency. Now, let us see what happens when *both* stator voltage and frequency are changed. In practice, supply voltage and frequency are varied in the **same proportion** in order to maintain a constant flux in the air-gap. For example, if voltage is doubled, then frequency is also doubled. Under these conditions, shape of the torque/speed curve remains the same but its position along the  $X$ -axis (*i.e.* speed axis) shifts with frequency.

Fig. 34.23 (a) shows the torque/speed curve of an 11.kW, 440-V, 60-Hz 3- $\phi$  SCIM. As seen, full-load speed is 1728 rpm and full-load torque is 45 N-m (point-A) whereas breakdown torque is 150 N-m and locked-rotor torque is 75 N-m.

Suppose, we now reduce both the voltage and frequency to **one-fourth** their original values *i.e.* to 110 V and 15 Hz respectively. As seen in Fig. 34.23 (b), the torque/speed curve shifts to the left. Now, the curve crosses the  $X$ -axis at the synchronous speed of  $120 \times 15/4 = 450$  rpm (*i.e.*  $1800/4 = 450$  rpm). Similarly, if the voltage and frequency are increased by 50% (660 V 90 Hz), the curve shifts to the right and cuts the  $X$ -axis at the synchronous speed of 2700 rpm.

Since the *shape* of the torque/speed curve remains the same at all **frequencies**, it follows that torque developed by a SCIM is the same **whenever slip-speed is the same**.

**Exampel 34.26.** A 440-V, 50-Hz, 4-pole, 3-phase SCIM develops a torque of 100 N-m at a speed of 1200 rpm. If the stator supply frequency is reduced by half, calculate

- the stator supply voltage required for maintaining the same flux in the machine.
- the new speed at a torque of 100 N-m.

**Solution.** (a) The stator voltage must be reduced in proportion to the frequency. Hence, it should also be reduced by half to  $440/2 = 220$  V.

(b) Synchronous speed at 50 Hz frequency =  $120 \times 50/4 = 1500$  rpm. Hence, slip speed for a torque of 100 N-m =  $1500 - 1200 = 300$  rpm.

Now, synchronous speed at 25 Hz =  $1500/2 = 750$  rpm.

Since slip-speed has to be the same for the same torque irrespective of the frequency, the new speed at 100 N-m is =  $750 + 300 = 1050$  rpm.

### 34.29. Current/Speed Curve of an Induction Motor

It is a  $V$ -shaped curve having a minimum value at synchronous speed. This minimum is equal to

the magnetising current which is needed to create flux in the machine. Since flux is purposely kept constant, it means that magnetising current is the same at all synchronous speeds.

Fig. 34.24

Fig. 34.24. shows the current/speed curve of the SCIM discussed in Art. 34.28 above. Refer Fig. 34.23(b) and Fig. 34.24. As seen, locked rotor current is 100 A and the corresponding torque is 75 N-m. If stator voltage and frequency are varied in the same proportion, current/speed curve has the same shape, but shifts along the speed axis. Suppose that voltage and frequency are reduced to one-fourth of their previous values *i.e.* to 110 V, 15 Hz respectively. Then, locked rotor current **decreases** to 75 A but corresponding torque **increases** to 150 N-m which is equal to full breakdown torque (Fig. 34.25).

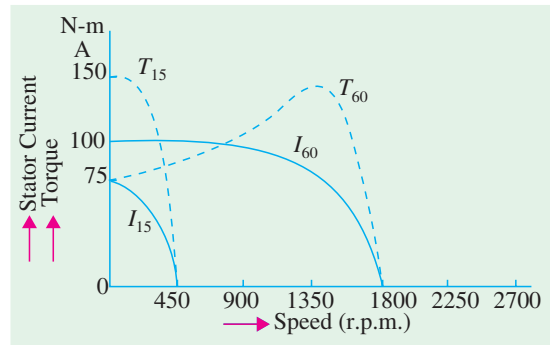

Fig. 34.25

It means that by reducing frequency, we can obtain **a larger torque with a reduced current**. This is one of the big advantages of frequency control method. By progressively increasing the voltage and current during the start-up period, a SCIM can be made to develop close to its breakdown torque all the way from zero to rated speed.

Fig. 34.26

Another advantage of frequency control is that it permits regenerative braking of the motor. In fact, the main reason for the popularity of frequency-controlled induction motor drives is their ability to develop high torque from zero to full speed together with the economy of regenerative braking.

### 34.30. Torque/Speed Characteristic Under Load

As stated earlier, stable operation of an induction motor lies over the linear portion of its torque/speed curve. The slope of this straight line depends

mainly on the rotor resistance. Higher the resistance, sharper the slope. This linear relationship between torque and speed (Fig. 34.26) enables us to establish a very simple equation between different parameters of an induction motor. The parameters under two different load conditions are related by the equation

$$s_2 = s_1 \cdot \frac{T_2}{T_1} \cdot \frac{R_2}{R_1} \left( \frac{V_1}{V_2} \right)^2 \quad \dots(i)$$

The only restriction in applying the above equation is that the new torque  $T_2$  must not be greater than  $T_1$  ( $V_2/V_1$ )<sup>2</sup>. In that case, the above equation yields an accuracy of better than 5% which is sufficient for all practical purposes.

**Example 34.24.** A 400-V, 60-Hz, 8-pole, 3-φ induction motor runs at a speed of 1140 rpm when connected to a 440-V line. Calculate the speed if voltage increases to 550V.

**Solution.** Here,  $s_1 = (1200 - 1140)/1200 = 0.05$ . Since everything else remains the same in Eq. (i) of Art. 34.30 except the slip and voltage, hence

$$S_2 = s_1 (V_1/V_2)^2 = 0.05 \times (440/550)^2 = 0.032 \quad \dots\text{Art. 34.23}$$

$$\therefore N_2 = 1200(1 - 0.032) = \mathbf{1161.6\text{ rpm.}}$$

**Example 34.25.** A 450-V, 60-Hz, 8-Pole, 3-phase induction motor runs at 873 rpm when driving a fan. The initial rotor temperature is 23° C. The speed drops to 864 rpm when the motor reaches its final temperature. Calculate (i) increase in rotor resistance and (ii) approximate temperature of the hot rotor if temperature coefficient of resistance is 1/234 per ° C.

**Solution.**  $s_1 = (900 - 873)/900 = 0.03$  and  $s_2 = (900 - 864)/900 = 0.04$

Since voltage and frequency etc. are fixed, the change in speed is entirely due to change in rotor resistance.

$$(i) \quad s_2 = s_1 (R_2/R_1) \quad \text{or} \quad 0.04 = 0.03 (R_2/R_1); \quad R_2 = 1.33 R_1$$

Obviously, the rotor resistance has increased by **33 percent**.

(ii) Let  $t_2$  be temperature of the rotor. Then, as seen from Art.1-11,

$$R_2 = R_1 [1 + \alpha (t_2 - 23)] \quad \text{or} \quad 1.33 R_1 = R_1 \left[ 1 + \frac{1}{234} (t_2 - 23) \right] \quad \therefore t_2 = \mathbf{100.2^\circ\text{C}}$$

### 34.31. Plugging of an Induction Motor

An induction motor can be quickly stopped by simply inter-changing any of its two stator leads. It reverses the direction of the revolving flux which produces a torque in the reverse direction, thus

Fig. 34.27

Induction asynchronous motor

applying brake on the motor. Obviously, during this so-called plugging period, **the motor acts as a brake**. It absorbs kinetic energy from the still

revolving load causing its speed to fall. The associated Power  $P_m$  is dissipated as heat in the rotor. At the same time, the rotor also continues to receive power  $P_2$  from the stator (Fig. 34.27) which is also dissipated as heat. Consequently, plugging produces rotor  $I^2R$  losses which even exceed those when the rotor is locked.

### 34.32. Induction Motor Operating as a Generator

When run *faster than* its synchronous speed, an induction motor runs as a generator called a **Induction generator**. It converts the mechanical energy it receives into electrical energy and this energy is released by the stator (Fig. 34.29). Fig. 34.28 shows an ordinary squirrel-cage motor which is driven by a petrol engine and is connected to a 3-phase line. As soon as motor speed exceeds its synchronous speed, it starts delivering **active** power  $P$  to the 3-phase line. However, for creating its own magnetic field, it absorbs **reactive** power  $Q$  from the line to which it is connected. As seen,  $Q$  flows in the **opposite** direction to  $P$ .

Fig. 34.28

Fig. 34.29

The active power **is directly proportional to the slip** above the synchronous speed. The reactive power required by the machine can also be supplied by a group of capacitors connected across its terminals (Fig. 34.30). This arrangement can be used to supply a 3-phase load without using an external source. The frequency generated is slightly less than that corresponding to the speed of rotation.

Fig. 34.30

The terminal voltage increases with capacitance. If capacitance is insufficient, the generator voltage will not build up. Hence, capacitor bank must be large enough to supply the reactive power normally drawn by the motor.

**Example 34.26.** A 440-V, 4-pole, 1470 rpm, 30-kW, 3-phase induction motor is to be used as an asynchronous generator. The rated current of the motor is 40 A and full-load power factor is 85%. Calculate

- (a) capacitance required per phase if capacitors are connected in delta.
- (b) speed of the driving engine for generating a frequency of 50 Hz.

**Solution. (i)** 
$$S = \sqrt{3} \cdot VI = 1.73 \times 440 \times 40 = 30.4 \text{ kVA}$$

$$P = S \cos \phi = 30.4 \times 0.85 = 25.8 \text{ kW}$$

$$Q = \sqrt{S^2 - P^2} = \sqrt{30.4^2 - 25.8^2} = 16 \text{ kVAR}$$

Hence, the  $\Delta$ -connected capacitor bank (Fig. 32.31) must provide  $16/3 = 5.333 \text{ kVAR}$  per phase.

Fig. 34.31

Capacitor current per phase is  $= 5,333/440 = 12 \text{ A}$ . Hence  $X_c = 440/12 = 36.6 \Omega$ . Now,

$$C = \frac{1}{2\pi f X_c} = 1/2\pi \times 50 \times 36.6 = \mathbf{87\mu F}$$

(ii) The driving engine must run at slightly more than synchronous speed. The slip speed is usually the same as that when the machine runs as a motor *i.e.* 30 rpm.

Hence, engine speed is  $= 1500 + 30 = \mathbf{1530 \text{ rpm}}$ .

### 34.33. Complete Torque/Speed Curve of a Three-Phase Machine

We have already seen that a 3-phase machine can be run as a **motor**, when it takes electric power and supplies mechanical power. The directions of torque and rotor rotation are in the **same** direction. The same machine can be used as an **asynchronous generator** when driven at a speed **greater** than the synchronous speed. In this case, it receives mechanical energy in the rotor and supplies electrical energy from the stator. The torque and speed are **oppositely-directed**.

The same machine can also be used as a **brake** during the plugging period (Art. 34.31). The three modes of operation are depicted in the torque/speed curve shown in Fig. 34.32.

Fig. 34.32

### Tutorial Problem No. 34.2

1. In a 3-phase, slip-ring induction motor, the open-circuit voltage across slip-rings is measured to be 110 V with normal voltage applied to the stator. The rotor is star-connected and has a resistance of  $1 \Omega$  and reactance of  $4 \Omega$  at standstill condition. Find the rotor current when the machine is (a) at standstill with slip-rings joined to a star-connected starter with a resistance of  $2\Omega$  per phase and negligible reactance (b) running normally with 5% slip. State any assumptions made.

[12.7 A ; 3.11 A] (Electrical Technology-I, Bombay Univ. 1978)

2. The star-connected rotor of an induction motor has a standstill impedance of  $(0.4 + j4)$  ohm per phase and the rheostat impedance per phase is  $(6 + j2)$  ohm. The motor has an induced e.m.f. of 80 V between slip-rings at standstill when connected to its normal supply voltage. Find (a) rotor current at standstill with the rheostat in the circuit (b) when the slip-rings are short-circuited and the motor is running with a slip of 3%. **[5.27 A ; 3.3 A]**
3. A 4-pole, 50-Hz induction motor has a full-load slip of 5%. Each rotor phase has a resistance of 0.3  $\Omega$  and a standstill reactance of 1.2  $\Omega$ . Find the ratio of maximum torque to full-load torque and the speed at which maximum torque occurs. **[2.6 ; 1125 r.p.m.]**
4. A 3-phase, 4-pole, 50-Hz induction motor has a star-connected rotor. The voltage of each rotor phase at standstill and on open-circuit is 121 V. The rotor resistance per phase is 0.3  $\Omega$  and the reactance at standstill is 0.8  $\Omega$ . If the rotor current is 15 A, calculate the speed at which the motor is running. Also, calculate the speed at which the torque is a maximum and the corresponding value of the input power to the motor, assuming the flux to remain constant. **[1444 r.p.m.; 937.5 r.p.m.]**
5. A 4-pole, 3-phase, 50 Hz induction motor has a voltage between slip-rings on open-circuit of 520 V. The star-connected rotor has a standstill reactance and resistance of 2.0 and 0.4  $\Omega$  per phase respectively. Determine :
  - (a) the full-load torque if full-load speed is 1,425 r.p.m.
  - (b) the ratio of starting torque to full-load torque
  - (c) the additional rotor resistance required to give maximum torque at standstill**[(a) 200 N-m (b) 0.82 (c) 1.6  $\Omega$ ] (Elect. Machines-II, Vikram Univ. Ujjain 1977)**
6. A 50-Hz, 8-pole induction motor has a full-load slip of 4 per cent. The rotor resistance is 0.001  $\Omega$  per phase and standstill reactance is 0.005  $\Omega$  per phase. Find the ratio of the maximum to the full-load torque and the speed at which the maximum torque occurs. **[2.6; 600 r.p.m.] (City & Guilds, London)**
7. A 3- $\phi$ , 50-Hz induction motor with its rotor star-connected gives 500 V (r.m.s.) at standstill between slip-rings on open circuit. Calculate the current and power factor in each phase of the rotor windings at standstill when joined to a star-connected circuit, each limb of which has a resistance of 10  $\Omega$  and an inductance of 0.03 H. The resistance per phase of the rotor windings is 0.2  $\Omega$  and inductance 0.03 H. Calculate also the current and power factor in each rotor phase when the rings are short-circuited and the motor is running with a slip of 4 per cent. **[13.6 A, 0.48; 27.0 A, 0.47] (London University)**
8. A 4-pole, 50-Hz, 3-phase induction motor has a slip-ring rotor with a resistance and standstill reactance of 0.04  $\Omega$  and 0.2  $\Omega$  per phase respectively. Find the amount of resistance to be inserted in each rotor phase to obtain full-load torque at starting. What will be the approximate power factor in the rotor at this instant ? The slip at full-load is 3 per cent. **[0.084  $\Omega$ , 0.516 p.f.] (London University)**
9. A 3- $\phi$  induction motor has a synchronous speed of 250 r.p.m. and 4 per cent slip at full-load. The rotor has a resistance of 0.02  $\Omega$ /phase and a standstill leakage reactance of 0.15  $\Omega$ /phase. Calculate (a) the ratio of maximum and full-load torque (b) the speed at which the maximum torque is developed. Neglect resistance and leakage of the stator winding. **[(a) 1.82 (b) 217 r.p.m.] (London University)**
10. The rotor of an 8-pole, 50-Hz, 3-phase induction motor has a resistance of 0.2  $\Omega$ /phase and runs at 720 r.p.m. If the load torque remains unchanged. Calculate the additional rotor resistance that will reduce this speed by 10% **[0.8  $\Omega$ ] (City & Guilds, London)**
11. A 3-phase induction motor has a rotor for which the resistance per phase is 0.1  $\Omega$  and the reactance per phase when stationary is 0.4  $\Omega$ . The rotor induced e.m.f. per phase is 100 V when stationary. Calculate the rotor current and rotor power factor (a) when stationary (b) when running with a slip of 5 per cent. **[(a) 242.5 A; 0.243 (b) 49 A; 0.98]**
12. An induction motor with 3-phase star-connected rotor has a rotor resistance and standstill reactance of 0.1  $\Omega$  and 0.5  $\Omega$  respectively. The slip-rings are connected to a star-connected resistance of 0.2  $\Omega$  per phase. If the standstill voltage between slip-rings is 200 volts, calculate the rotor current per phase when the slip is 5%, the resistance being still in circuit. **[19.1 A]**
13. A 3-phase, 50-Hz induction motor has its rotor windings connected in star. At the moment of starting

the rotor, induced e.m.f. between each pair of slip-rings is 350 V. The rotor resistance per phase is  $0.2 \Omega$  and the standstill reactance per phase is  $1 \Omega$ . Calculate the rotor starting current if the external starting resistance per phase is  $8 \Omega$  and also the rotor current when running with slip-rings short-circuited, the slip being 3 per cent. **[24.5 A ; 30.0 A]**

14. In a certain 8-pole, 50-Hz machine, the rotor resistance per phase is  $0.04 \Omega$  and the maximum torque occurs at a speed of 645 r.p.m. Assuming that the air-gap flux is constant at all loads, determine the percentage of maximum torque (a) at starting (b) when the slip is 3%.

**[(a) 0.273 (b) 0.41] (London University)**

15. A 6-pole, 3-phase, 50-Hz induction motor has rotor resistance and reactance of  $0.02 \Omega$  and  $0.1 \Omega$  respectively per phase. At what speed would it develop maximum torque ? Find out the value of resistance necessary to give half of maximum torque at starting.

**[800 rpm;  $0.007 \Omega$ ] (Elect.Engg. Grad I.E.T.E. June 1988)**

### 34.34. Measurement of Slip

Following are some of the methods used for finding the slip of an induction motor whether squirrel-cage or slip-ring type.

**(i) By actual measurement of motor speed**

This method requires measurement of actual motor speed  $N$  and calculation of synchronous speed  $N_s$ .  $N$  is measured with the help of a speedometer and  $N_s$  calculated from the knowledge of supply frequency and the number of poles of the motor.\* Then slip can be calculated by using the equation.

$$s = (N_s - N) \times 100 / N_s$$

**(ii) By comparing rotor and stator supply frequencies**

This method is based on the fact that  $s = f_r / f$

Since  $f$  is generally known,  $s$  can be found if frequency of rotor current can be measured by some method. In the usual case, where  $f$  is 50 Hz,  $f_r$  is so low that individual cycles can be easily counted. For this purpose, a d.c. moving-coil millivoltmeter, preferably of centre-zero, is employed as described below :

**(a)** In the case of a slip-ring motor, the leads of the millivoltmeter are lightly pressed against the adjacent slip-rings as they revolve (Fig. 34.33). Usually, there is sufficient voltage drop in the brushes and their short-circuiting strap to provide an indication on the millivoltmeter. The current in the millivoltmeter follows the variations of the rotor current and hence the pointer oscillates about its mean zero position. The number of complete cycles made by the pointer per second can be easily counted (it is worth remembering that one cycle consists of a movement from zero to a maximum to the right, back to zero and on to a maximum to the left and then back to zero).

As an example, consider the case of a 4-pole motor fed from a 50-Hz supply and running at 1,425 r.p.m. Since

Fig. 34.33

Fig. 34.34

\* Since an induction motor does not have salient poles, the number of poles is usually inferred from the no-load speed or from the rated speed of the motor.

$N_s = 1,500$  r.p.m., its slip is 5% or 0.05. The frequency of the rotor current would be  $f_r = s_f = 0.05 \times 50 = 2.5$  Hz which (being slow enough) can be easily counted.

(b) For squirrel-cage motors (which do not have slip-rings) it is not possible to employ the millivoltmeter so **directly**, although it is sometimes possible to pick up some voltage by connecting the millivoltmeter across the ends of the motor shaft (Fig. 34.34)

Another method, sometime employed, is as follows :

A large flat search coil of many turns is placed centrally against the end plate on the non-driving end of the motor. Quite often, it is possible to pick up sufficient voltage by induction from the leakage fluxes to obtain a reading on the millivoltmeter. Obviously, a large 50-Hz voltage will also be induced in the search coil although it is too rapid to affect the millivoltmeter. Commercial slip-indicators use such a search coil and, in addition, contain a low-pass filter amplifier for eliminating fundamental frequency and a bridge circuit for comparing stator and rotor current frequencies.

**(iii) Stroboscopic Method**

In this method, a circular metallic disc is taken and painted with alternately black and white segments. The number of segments (both black and white) is equal to the number of poles of the motor. For a 6-pole motor, there will be six segments, three black and three white, as shown in Fig. 34.35(a). The painted disc is mounted on the end of the shaft and illuminated by means of a neon-filled stroboscopic lamp, which may be supplied preferably with a combined d.c. and a.c. supply although only a.c. supply will do\*. The connections for combined supply are shown in Fig. 34.36 whereas Fig. 34.35 (b) shows the connection for a.c. supply only. It must be noted that with combined d.c. and a.c. supply, the lamp will flash once per cycle\*\*. But with a.c. supply, it will flash twice per cycle.

Fig. 34.35

Consider the case when the revolving disc is seen in the flash light of the bulb which is fed by the combined d.c. and a.c. supply.

If the disc were to rotate at synchronous speed, it would appear to be stationary. Since, in actual practice, its speed is slightly less than the synchronous speed, it appears to rotate slowly backwards. The reason for this apparent backward movement is as follows :

Fig. 34.36

\* When combined d.c. and a.c. supply is used, the lamp should be tried both ways in its socket to see which way it gives better light.

\*\* It will flash only when the two voltages add and remain extinguished when they oppose.

Let Fig. 34.37(a) represent the position of the white lines when they are illuminated by the first flash. When the next flash comes, they have **nearly** reached positions 120° ahead (but not quite), as shown in Fig. 34.37(b). Hence, line No. 1 has **almost** reached the position previously occupied by line No. 2 and one flash still later [Fig. 34.37 (c)] it has **nearly** reached the position previously occupied by line No. 3 in Fig. 34.37(a).

Fig. 34.37

By counting the number of lines passing a fixed point in, say, a minute and dividing by the number of lines seen (*i.e.* three in the case of a 6-pole motor and so on) the apparent backward speed in r.p.m. can be found. This gives slip-speed in r.p.m. *i.e.*  $N_s - N$ . The slip may be found from the

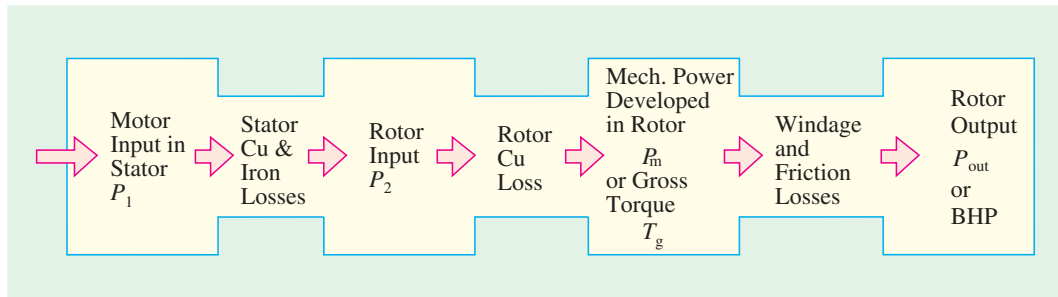

$$\text{relation } s = \frac{N_s - N}{N_s} \times 100$$

**Note.** If the lamp is fed with a.c. supply alone, then it will flash twice per cycle and twice as many lines will be seen rotating as before.

### 34.35. Power Stages in an Induction Motor

Stator iron loss (consisting of eddy and hysteresis losses) depends on the supply frequency and the flux density in the iron core. It is practically constant. The iron loss of the rotor is, however, negligible because frequency of rotor currents under normal running conditions is always small. Total rotor Cu loss =  $3 I_2^2 R_2$ .

Different stages of power development in an induction motor are as under :

A better visual for power flow, within an induction motor, is given in Fig. 34.38.

### 34.36. Torque Developed by an Induction Motor

An induction motor develops gross torque  $T_g$  due to gross rotor output  $P_m$  (Fig 34.38). Its value can be expressed either in terms of rotor input  $P_2$  or rotor gross output  $P_m$  as given below.

$$T_g = \frac{P_2}{\omega_s} = \frac{P_m}{2\pi N_s} \quad \dots \text{in terms of rotor input}$$

Fig. 34.38

$$T_g = \frac{P_m}{\omega} = \frac{P_m}{2\pi N} \quad \dots \text{ in terms of rotor output}$$

The shaft torque  $T_{sh}$  is due to output power  $P_{out}$  which is less than  $P_m$  because of rotor friction and windage losses.

$$\therefore T_{sh} = P_{out}/\omega = P_{out}/2\pi N$$

The difference between  $T_g$  and  $T_{sh}$  equals the torque lost due to friction and windage loss in the motor.

In the above expressions,  $N$  and  $N_s$  are in r.p.s. However, if they are in r.p.m., the above expressions for motor torque become

$$\begin{aligned} T_g &= \frac{P_2}{2\pi N_s/60} = \frac{60}{2\pi} \cdot \frac{P_2}{N_s} = 9.55 \frac{P_2}{N_s} \text{ N-m} \\ &= \frac{P_m}{2\pi N/60} = \frac{60}{2\pi} \cdot \frac{P_m}{N} = 9.55 \frac{P_m}{N} \text{ N-m} \\ T_{sh} &= \frac{P_{out}}{2\pi N/60} = \frac{60}{2\pi} \cdot \frac{P_{out}}{N} = 9.55 \frac{P_{out}}{N} \text{ N-m} \end{aligned}$$

### 34.37. Torque, Mechanical Power and Rotor Output

Stator input  $P_1 = \text{stator output} + \text{stator losses}$   
 The stator output is transferred entirely inductively to the rotor circuit.

Obviously, rotor input  $P_2 =$  stator output  
 Rotor gross output,  $P_m =$  rotor input  $P_2$  — rotor Cu losses

The type DF200 diesel electric locomotive is the first motor-driven train equipped with diesel generators since 1958. It adopted induction motors to realize high acceleration, high speed, and large torque, which resulted in a quick-response generator brake system.

This rotor output is converted into mechanical energy and gives rise to gross torque  $T_g$ . Out of this gross torque developed, some is lost due to windage and friction losses in the rotor and the rest appears as the useful or shaft torque  $T_{shr}$ .

Let  $N$  r.p.s. be the actual speed of the rotor and if  $T_g$  is in N-m, then

$$T_g \times 2\pi N = \text{rotor gross output in watts, } P_m$$

$$\therefore T_g = \frac{\text{rotor gross output in watts, } P_m}{2\pi N} \text{ N-m}^* \quad \dots(1)$$

If there were no Cu losses in the rotor, then rotor output will equal rotor input and the rotor will run at synchronous speed.

$$\therefore T_g = \frac{\text{rotor input } P_2}{2\pi N_s} \quad \dots(2)$$

From (1) and (2), we get,

Rotor gross output  $P_m = T_g \omega = T_g \times 2\pi N$

Rotor input  $P_2 = T_g \omega_s = T_g \times 2\pi N_s$  ... (3)

The difference of two equals rotor Cu loss.

$$\therefore \text{rotor Cu loss} = P_2 - P_m = T_g \times 2\pi (N_s - N) \quad \dots(4)$$

From (3) and (4),

$$\frac{\text{rotor Cu loss}}{\text{rotor input}} = \frac{N_s - N}{N_s} = s$$

$$\therefore \text{rotor Cu loss} = s \times \text{rotor input} = s \times \text{power across air-gap} = s P_2 \quad \dots(5)$$

Also, rotor input = rotor Cu loss/s

Rotor gross output,  $P_m = \text{input } P_2 - \text{rotor Cu loss} = \text{input} - s \times \text{rotor input}$

$$= (1 - s) \text{ input } P_2 \quad \dots(6)$$

$$\therefore \text{rotor gross output } P_m = (1 - s) \text{ rotor input } P_2$$

or  $\frac{\text{rotor gross output, } P_m}{\text{rotor input, } P_2} = 1 - s = \frac{N}{N_s}; \quad \frac{P_m}{P_2} = \frac{N}{N_s}$

$$\therefore \text{rotor efficiency} = \frac{N}{N_s} \quad \text{Also, } \frac{\text{rotor Cu loss}}{\text{rotor gross output}} = \frac{s}{1 - s}$$

**Important Conclusion**

If some power  $P_2$  is delivered to a rotor, then a part  $sP_2$  is lost in the rotor itself as copper loss (and appears as heat) and the remaining  $(1 - s)P_2$  appears as gross mechanical power  $P_m$  (including friction and windage losses).

$$\therefore P_2 : P_m : P_{cr} :: 1 : (1 - s) : s \quad \text{or} \quad P_2 : P_m : P_{cr} :: 1 : (1 - s) : s$$

\* The value of gross torque in kg-m is given by

$$T_g = \frac{\text{rotor gross output in watts}}{9.81 \times 2\pi N} \text{ kg-m.} = \frac{P_m}{9.81 \times 2\pi N} \text{ kg-m}$$

The rotor input power will always divide itself in this ratio, hence it is advantageous to run the motor with as small a slip as possible.

**Example 34.27.** The power input to the rotor of 440 V, 50 Hz, 6-pole, 3-phase, induction motor is 80 kW. The rotor electromotive force is observed to make 100 complete alterations per minute. Calculate (i) the slip, (ii) the rotor speed, (iii) rotor copper losses per phase. [Madras University, 1997]

**Solution.** 100 alterations/minute =  $\frac{100}{60}$  cycles/sec

$$1.6667 \text{ Hz} = sf$$

Hence, the slip,  $s = \frac{1.6667}{50} = 0.3333 \text{ P.u. or } 3.333\%$

(ii) rotor speed,  $N = (1 - s) N_s = (1 - 0.03333) \times 1000$

Since  $N_s = \frac{120 \times 50}{6} = 1000 \text{ rpm}$ ,  $N = 966.67 \text{ rpm}$

(iii) rotor copper losses/phase =  $\frac{1}{3} \times (s \times \text{rotor input})$

$$\text{total rotor power input} = 80 \text{ kW}$$

$$\text{rotor power input per phase} = 80/3 \text{ kW}$$

rotor copper losses per phase

$$= \frac{0.0333 \times 80}{3} \text{ kW} = 0.8888 \text{ kW}$$

**Example 34.28.** A 440-V, 3- $\phi$ , 50-Hz, 4-pole, Y-connected induction motor has a full-load speed of 1425 rpm. The rotor has an impedance of  $(0.4 + j4)$  ohm and rotor/stator turn ratio of 0.8. Calculate (i) full-load torque (ii) rotor current and full-load rotor Cu loss (iii) power output if windage and friction losses amount to 500 W (iv) maximum torque and the speed at which it occurs (v) starting current and (vi) starting torque.

**Solution.**  $N_s = 120 \times 50/4 = 1500 \text{ rpm} = 25 \text{ rps}$ ,  $s = 75/1500 = 0.05$   
 $E_1 = 440/1.73 = 254 \text{ V/phase}$

(i) Full-load  $T_f = \frac{3}{2\pi \times 25} \times \frac{0.05 (0.8 \times 254)^2 \times 0.4}{(0.4)^2 + (0.05 \times 4)^2}$   
 $= 78.87 \text{ N-m}$

(ii)  $I_r = \frac{sE_2}{\sqrt{R_2^2 + (sX_2)^2}} = \frac{sKE_1}{\sqrt{R_2^2 + (sX_2)^2}} = \frac{0.05 \times (0.8 \times 254)}{\sqrt{(0.4)^2 + (0.05 \times 4)^2}}$   
 $= 22.73 \text{ A}$

Total Cu loss =  $3I_r^2 R = 3 \times 22.73^2 \times 0.4 = 620 \text{ W}$

(iii) Now,  $P_m = 2\pi NT = 2\pi \times (1425/60) \times 78.87 = 11,745 \text{ W}$

$\therefore P_{\text{out}} = P_m - \text{windage and friction loss} = 11,745 - 500 = 11,245 \text{ W}$

(iv) For maximum torque,  $s = R_2/X_2 = 0.4/4 = 0.1$

$\therefore T_{\text{max}} = \frac{3}{2\pi \times 25} \times \frac{0.1 \times (0.8 \times 254)^2 \times 0.4}{(0.4)^2 + (0.1 \times 4)^2} = 98.5 \text{ N-m}$

Since  $s = 0.1$ , slip speed =  $sN_s = 0.1 \times 1500 = 150 \text{ rpm}$ .

$\therefore$  Speed for maximum torque =  $1500 - 150 = 1350 \text{ rpm}$ .

$$\begin{aligned}
 \text{(v) starting current} &= \frac{E_2}{\sqrt{R_2^2 + X_2^2}} = \frac{KE_1}{\sqrt{R_2^2 + X_2^2}} = \frac{0.8 \times 254}{\sqrt{0.4^2 + 4^2}} = \mathbf{50.5 \text{ A}} \\
 \text{(vi) At start,} & \quad s = 1, \text{ hence} \\
 T_{st} &= \frac{3}{2\pi \times 25} \times \frac{(0.8 \times 254)^2 \times 0.4}{(0.4)^2 + 4^2} = \mathbf{19.5 \text{ N}\cdot\text{m}}
 \end{aligned}$$

It is seen that as compared to full-load torque, the starting torque is much less—almost 25 per cent.

### 34.38. Induction Motor Torque Equation

The gross torque  $T_g$  developed by an induction motor is given by

$$\begin{aligned}
 T_g &= P_2 / 2\pi N_s && -N_s \text{ in r.p.s.} \\
 &= 60 P_2 / 2\pi N_s = 9.55 P_2 / N_s && -N_s \text{ in r.p.m.}
 \end{aligned}$$

Now,

$$P_2 = \text{rotor Cu loss}/s = 3I_2^2 R_2 / s$$

$$\text{As seen from Art. 34.19, } I_2 = \frac{sE_2}{\sqrt{R_2^2 + (sX_2)^2}} = \frac{sKE_1}{\sqrt{R_2^2 + (sX_2)^2}}$$

where  $K$  is rotor/stator turn ratio per phase.

$$\therefore P_2 = 3 \times \frac{s^2 E_2^2 R_2}{R_2^2 + (sX_2)^2} \times \frac{1}{s} = \frac{3s E_2^2 R_2}{R_2^2 + (sX_2)^2}$$

Also,

$$P_2 = 3 \times \frac{s^2 K^2 E_1^2 R_2}{R_2^2 + (sX_2)^2} \times \frac{1}{s} = \frac{3s K^2 E_1^2 R_2}{R_2^2 + (sX_2)^2}$$

$$\therefore T_g = \frac{P_2}{2\pi N_s} = \frac{3}{2\pi N_s} \times \frac{s E_2^2 R_2}{R_2^2 + (sX_2)^2} \quad \text{— in terms of } E_2$$

$$\text{or} \quad T_g = \frac{3}{2\pi N_s} \times \frac{s K^2 E_1^2 R_2}{R_2^2 + (sX_2)^2} \quad \text{— in terms of } E_1$$

Here,  $E_1$ ,  $E_2$ ,  $R_2$  and  $X_2$  represent phase values.

In fact,  $3K^2/2\pi N_s = k$  is called the constant of the given machine. Hence, the above torque equation may be simplified to

$$T_g = k \frac{s E_1^2 R_2}{R_2^2 + (sX_2)^2} \quad \text{— in terms of } E_1$$

### 34.39. Synchronous Watt

It is clear from the above relations that torque is proportional to rotor input. By defining a new unit of torque (instead of the force-at-radius unit), we can say that the rotor torque *equals* rotor input. The new unit is synchronous watt. When we say that a motor is developing a torque of 1,000 synchronous watts, we mean that the rotor input is 1,000 watts and that the torque is such that power developed would be 1,000 watts provided the rotor were running synchronously and developing the same torque.

Or

Synchronous watt is that torque which, at the synchronous speed of the machine under consideration, would develop a power of 1 watt.

$$\text{rotor input} = T_{sw} \times 2\pi N_s \quad \therefore T_{sw} = \frac{\text{rotor input, } P_2}{2\pi \times \text{synch. speed}}$$

$$= \frac{1}{\omega_s} \cdot \frac{N_s}{N} \cdot P_g = \frac{1}{\omega_s} \cdot \frac{N_s}{N} \cdot P_m$$

**Synchronous wattage of an induction motor equals the power transferred across the air-gap to the rotor.**

$$\begin{aligned} \therefore \text{torque in synchronous watt} \\ = \text{rotor input} = \frac{\text{rotor Cu loss}}{s} = \frac{\text{gross output power, } P_m}{(1-s)} \end{aligned}$$

Obviously, at  $s = 1$ , torque in synchronous watt equals the total rotor Cu loss because at standstill, entire rotor input is lost as Cu loss.

Suppose a 23-kW, 4-pole induction motor has an efficiency of 92% and a speed of 1440 r.p.m. at rated load. If mechanical losses are assumed to be about 25 per cent of the total losses, then

$$\text{motor input} = 23/0.92 = 25 \text{ kW, total loss} = 25 - 23 = 2 \text{ kW.}$$

$$\text{Friction and windage loss} = 2/4 = 0.5 \text{ kW}$$

$$\therefore P_m = 23 + 0.5 = 23.5 \text{ kW}$$

$$\text{Power in synchronous watts } P_{sw} = P_2 = 23.5 \times 1500/1440 = 24.5 \text{ kW}$$

$$\text{synchronous speed } \omega_s = 2\pi (1500/60) = 157 \text{ rad/s}$$

$$\therefore \text{synchronous torque, } T_{sw} = 24.5 \times 10^3 / 157 = 156 \text{ N-m}$$

$$\begin{aligned} \text{or } T_{sw} &= P_m \frac{N_s}{N} \cdot \frac{1}{\omega_s} = 23.5 \times \frac{1500}{1440} \times \frac{1}{2\pi (1500/60)} \\ &= 156 \text{ N-m} \end{aligned} \quad \text{---Art 34.39}$$

### 34.40. Variations in Rotor Current

The magnitude of the rotor current varies with load carried by the motor.

As seen from Art. 34.37

$$\frac{\text{rotor output}}{\text{rotor input}} = \frac{N}{N_s} \text{ or rotor output} = \text{rotor input} \times \frac{N}{N_s}$$

$$\therefore \text{rotor input} = \text{rotor output} \times N_s / N$$

$$\text{Also, rotor output} \propto 2\pi N T = k N T$$

$$\therefore \text{rotor input} = k N T \times N_s / N = k N_s T$$

$$\text{Now, } \frac{\text{rotor Cu loss}}{\text{rotor input}} = s \text{ or } \frac{3 I_2^2 R_2}{s} = \text{rotor input}$$

$$\therefore 3 I_2^2 R_2 / s = k N_s T \text{ or } T \propto I_2^2 R_2 / s$$

$$\begin{aligned} T_{st} &\propto I_{2st}^2 R_2 && \text{--- since } s = 1 \\ T_f &\propto I_{2f}^2 R_2 / s_f && \text{--- } s_f = \text{full-load slip} \end{aligned}$$

$$\therefore \frac{T_{st}}{T_f} = s_f \left( \frac{I_{2st}}{I_{2f}} \right)^2$$

where  $I_{2st}$  and  $I_{2f}$  are the rotor currents for starting and full-load running conditions.

### 34.41. Analogy with a Mechanical Clutch

We have seen above that, rotor Cu loss = slip  $\times$  rotor input

This fact can be further clarified by considering the working of a mechanical clutch (though it is

not meant to be a proof for the above) similar to the one used in automobiles. A plate clutch is shown in Fig. 34.39. It is obvious that the torque on the driving shaft must exactly equal the torque on the driven shaft. In fact, these two torques are actually one and the same torque, because the torque is caused by friction between the discs and it is true whether the clutch is slipping or not. Let  $\omega_1$  and  $\omega_2$  be the angular velocities of the shaft when the clutch is slipping.

Fig. 34.39

Then, input =  $T \omega_1$  and output =  $T \omega_2 = T \omega_1(1 - s)$  : [  $\because \omega_2 = \omega_1(1 - s)$  ]

$$\text{loss} = T \omega_1 - T \omega_2 = T \omega_1 - T \omega_1(1 - s) = sT \omega_1 = \text{slip} \times \text{input}$$

### 34.42. Analogy with a D.C. Motor

The above relations could also be derived by comparing an induction motor with a d.c. motor. As shown in Art 29.3, in a d.c. shunt motor, the applied voltage is always opposed by a back e.m.f.  $E_b$ . The power developed in the motor armature is  $E_b I_a$  where  $I_a$  is armature current. This power, as we know, is converted into mechanical power in the armature of the motor.

Now, in an induction motor, it is seen that the induced e.m.f in the rotor decreases from its standstill value of  $E_2$  to  $sE_2$  when in rotation. Obviously, the difference  $(1 - s) E_2$  is the e.m.f. called forth by the rotation of the rotor similar to the back e.m.f. in a d.c. motor. Hence, gross power  $P_m$  developed in the rotor is given by the product of the back e.m.f., armature current and rotor power factor.

$$P_m = (1 - s)E_2 \times I_2 \cos \phi_2 ; \quad \text{Now } I_2 = \frac{sE_2}{\sqrt{[R_2^2 + (sX_2)^2]}} \text{ and } \cos \phi_2 = \frac{R_2}{\sqrt{[R_2^2 + (sX_2)^2]}}$$

$$\therefore P_m = (1 - s)E_2 \times \frac{sE_2}{\sqrt{[R_2^2 + (sX_2)^2]}} \times \frac{R_2}{\sqrt{[R_2^2 + (sX_2)^2]}} = \frac{s(1 - s)E_2^2 R_2}{R_2^2 + (sX_2)^2}$$

Multiplying the numerator and the denominator by  $s$ , we get

$$P_m = \left( \frac{1 - s}{s} \right) R_2 \times \frac{s^2 E_2^2}{[R_2^2 + (sX_2)^2]} = \left( \frac{1 - s}{s} \right) I_2^2 R_2 \quad \left( \because I_2 = \frac{sE_2}{\sqrt{[R_2^2 + (sX_2)^2]}} \right)$$

Now,  $I_2^2 R_2 = \text{rotor Cu loss/phase} \quad \therefore \frac{\text{Cu loss}}{\text{rotor output}} = \frac{s}{1 - s}$

This is the same relationship as derived in Art. 34-37.

**Example 34.30.** The power input to a 3-phase induction motor is 60 kW. The stator losses total 1 kW. Find the mechanical power developed and the rotor copper loss per phase if the motor is running with a slip of 3%.

(Elect. Machines AMIE Sec. E Summer 1991)

**Solution.** Rotor input,  $P_2 = \text{stator input} - \text{stator losses} = 60 - 1 = 59 \text{ kW}$

$$P_m = (1 - s)P_2 = (1 - 0.03) \times 59 = 57.23 \text{ kW}$$

$$\text{Total rotor Cu loss} = sP_2 = 0.03 \times 59 = 1.77 \text{ kW} = 1770 \text{ W}$$

$$\text{Rotor Cu loss/phase} = 1770/3 = 590 \text{ W}$$

**Example 34.31.** The power input to the rotor of a 400 V, 50-Hz, 6-pole, 3-phase induction motor is 20 kW. The slip is 3%. Calculate (i) the frequency of rotor currents (ii) rotor speed (iii) rotor copper losses and (iv) rotor resistance per phase if rotor current is 60 A.

(Elect. Engg. Punjab Univ. 1991)

- Solution.** (i) Frequency of rotor current =  $sf = 0.03 \times 50 = 1.5$  Hz  
 (ii)  $N_s = 120 \times 50/6 = 1000$  rpm;  $N = 1000(1 - 0.03) = 700$  rpm  
 (iii) rotor Cu loss =  $s \times$  rotor input =  $0.03 \times 20 = 0.6$  kW = 600 W  
 (iv) rotor Cu loss/phase = 200 W;  $\therefore 60^2 R_2 = 200$ ;  $R_2 = 0.055 \Omega$

**Example 34.32.** A 3-phase, 6-pole, 50-Hz induction motor develops 3.73 kW at 960 rpm. What will be the stator input if the stator loss is 280 W?

(Madurai Kamraj Univ. 1999)

**Solution.** As seen from Art. 34.37,  $\frac{\text{power developed in rotor}}{\text{rotor input}} = \frac{N}{N_s}$

Now, mechanical power developed in rotor = 3.73 kW.,  $N_s = 120 \times 50/6 = 1000$  r.p.m.

$\therefore 3,730/\text{rotor input} = 960/1000 \quad \therefore \text{rotor input} = 3,885$  W

Stator input = rotor input + stator losses =  $3885 + 280 = 4,156$  W

**Example 34.33.** The power input to the rotor of a 400 V, 50-Hz, 6-pole, 3- $\phi$  induction motor is 75 kW. The rotor electromotive force is observed to make 100 complete alteration per minute. Calculate:

(i) slip (ii) rotor speed (iii) rotor copper losses per phase (iv) mechanical power developed.

(Elect. Engg. I, Nagpur Univ. 1993)

**Solution.** Frequency of rotor emf,  $f' = 100/60 = 5/3$  Hz

(i) Now,  $f' = sf$  for  $5/3 = s \times 50$ ;  $s = 1/30 = 0.033$  or **3.33%**

(ii)  $N_s = 120 \times 50/6 = 1000$  rpm;  $N = N_s(1 - s) = 1000(1 - 1/30) = 966.7$  rpm

(iii)  $P_2 = 75$  kW; total rotor Cu loss =  $sP_2 = (1/30) \times 75 = 2.5$  kW  
 rotor Cu loss/phase =  $2.5/3 = 0.833$  kW

(iv)  $P_m = (1 - s)P_2 = (1 - 1/30) \times 75 = 72.5$  kW

**Example 34.34.** The power input to a 500 V, 50-Hz, 6-pole, 3-phase induction motor running at 975 rpm is 40 kW. The stator losses are 1 kW and the friction and windage losses total 2 kW. Calculate: (i) the slip (ii) the rotor copper loss (iii) shaft power and (iv) the efficiency.

(Elect. Engg. - II, Pune Univ. 1989)

**Solution.** (i)  $N_s = 120 \times 50/6 = 1000$  rpm;  $s = (100 - 975)/1000 = 0.025$  or 2.5%

(ii) Motor input  $P_1 = 40$  kW; stator loss = 1 kW; rotor input  $P_2 = 40 - 1 = 39$  kW

$\therefore$  rotor Cu loss =  $s \times$  rotor input =  $0.025 \times 39 = 0.975$  kW

(iii)  $P_m = P_2 -$  rotor Cu loss =  $39 - 0.975 = 38.025$  kW

$P_{out} = P_m -$  friction and windage loss =  $38.025 - 2 = 36.025$  kW

(iv)  $\eta = P_{out}/P_1 = 36.025/40 = 0.9$  or **90%**

**Example 34.35.** A 100-kW (output), 3300-V, 50-Hz, 3-phase, star-connected induction motor has a synchronous speed of 500 r.p.m. The full-load slip is 1.8% and F.L. power factor 0.85. Stator copper loss = 2440 W. Iron loss = 3500 W. Rotational losses = 1200 W. Calculate (i) the rotor copper loss (ii) the line current (iii) the full-load efficiency.

(Elect. Machines, Nagpur Univ. 1993)

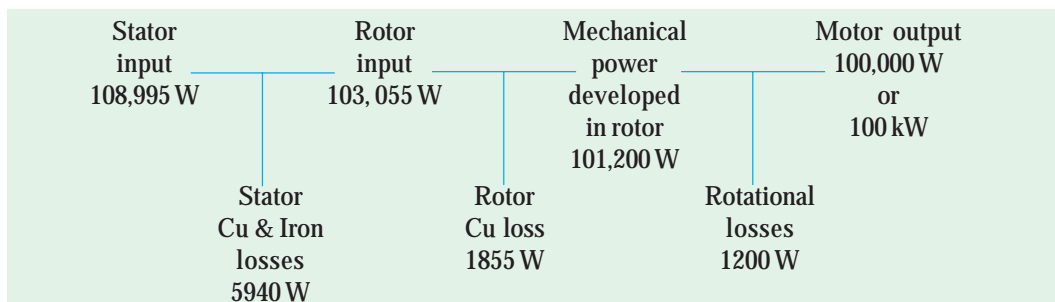

**Solution.**  $P_m = \text{output} + \text{rotational loss} = 100 + 1.2 = 101.2 \text{ kW}$

(i) rotor Cu loss =  $\frac{s}{1-s} \times P_m = \frac{0.018}{1-0.018} \times 101.2 = 1.855 \text{ kW}$

(ii) rotor input,  $P_2 = P_m + \text{rotor Cu loss} = 101.2 + 1.855 = 103.055 \text{ kW}$   
 Stator input =  $P_2 + \text{stator Cu and iron losses}$   
 =  $103.055 + 2.44 + 3.5 = 108.995 \text{ kW}$

$\therefore 108,995 = \sqrt{3} \times 3300 \times I_L \times 0.85; \quad I_L = 22.4 \text{ A}$

The entire power flow in the motor is given below.

(iii) F.L. efficiency =  $100,000/108,995 = 0.917$  or **91.7%**

**Example 34.36.** The power input to the rotor of a 440 V, 50-Hz, 6-pole, 3-phase induction motor is 100 kW. The rotor electromotive force is observed to make 120 cycles per minute. Calculate (i) the slip (ii) the rotor speed (iii) mechanical power developed (iv) the rotor copper loss per phase and (v) speed of stator field with respect to rotor. (Elect. Engg. AMIETE Sec. A June 1991)

**Solution.** (i)  $f' = sf$  or  $(120/60) = s \times 50; s = 0.01$

(ii)  $N_s = 120 \times 50/6 = 1000 \text{ rpm}; N = 1000(1 - 0.01) = 990 \text{ rpm}$

(iii)  $P_m (1 - s) P_2 = (1 - 0.01) \times 100 = 99 \text{ kW}$

(iv) total rotor Cu loss =  $sP_2 = 0.01 \times 100 = 1 \text{ kW}; \text{ Cu loss/phase} = 1/3 \text{ kW}$

(v)  $N_s = 1000 \text{ rpm}; N = 990 \text{ rpm}$ . Hence, speed of stator field with respect to rotor is  $= 1000 - 990 = 10 \text{ rpm}$ .

**Example 34.37.** An induction motor has an efficiency of 0.9 when delivering an output of 37 kW. At this load, the stator Cu loss and rotor Cu loss each equals the stator iron loss. The mechanical losses are one-third of the no-load loss. Calculate the slip.

(Adv. Elect. Machines, A.M.I.E. Sec. B Winter 1993)

**Solution.** Motor input =  $37,000/0.9 = 41,111 \text{ W}$

$\therefore \text{total loss} = 41,111 - 37,000 = 4,111 \text{ W}$

This includes (i) stator Cu and iron losses (ii) rotor Cu loss (its iron loss being negligibly small) and (iii) rotor mechanical losses.

Now, no-load loss of an induction motor consists of (i) stator iron loss and (ii) mechanical losses provided we neglect the small amount of stator Cu loss under no-load condition. Moreover, these two losses are independent of the load on the motor.

no-load loss =  $W_i + W_m = 3W_m$

$\therefore W_m = W_i/2$

where  $W_i$  is the stator iron loss and  $W_m$  is the rotor mechanical losses.

Let, stator iron loss =  $x$ ; then stator Cu loss =  $x$ ; rotor Cu loss =  $x$ ; mechanical loss =  $x/2$

$$\therefore 3x + x/2 = 4,111 \text{ or } x = 1175 \text{ W}$$

$$\begin{aligned} \text{Now, rotor input} &= \text{gross output} + \text{mechanical losses} + \text{rotor Cu loss} \\ &= 37,000 + (1175/2) + 1175 = 38,752 \text{ W} \end{aligned}$$

$$s = \frac{\text{rotor Cu loss}}{\text{rotor input}} = \frac{1175}{38,752} = 0.03 \text{ or } 3\%.$$

**Example 34.38.** A 400 V, 50-Hz, 6-pole,  $\Delta$ -connected, 3- $\phi$  induction motor consumes 45 kW with a line current of 75 A and runs at a slip of 3%. If stator iron loss is 1200 kW, windage and friction loss is 900 W and resistance between two stator terminals is 0.12  $\Omega$ , calculate (i) power supplied to the rotor  $P_2$  (ii) rotor Cu loss  $P_{cr}$  (iii) power supplied to load  $P_{out}$  (iv) efficiency and (v) shaft torque developed.

**Solution.**  $\cos \phi = \frac{45 \times 1000}{\sqrt{3} \times 400 \times 75} = 0.866 \text{ lag}$

A line current of 75 amp means a phase-current of  $75/\sqrt{3}$  i.e. 43.3 amp

Next, winding resistance has to be worked out

Refer to Fig. 34.40.

$r$  and  $2r$  in parallel have an equivalent resistance measured at  $a$  and  $b$  in delta connected motor as  $r \times 2r/3r = 2r/3$  ohms

From the data given  $\frac{2r}{3} = 0.12, r = 0.18$

Total stator copper loss =  $3 \times 43.3^2 \times 0.18 = 1012$

Watts

Fig. 34.40

$$\begin{aligned} \text{Total input to stator} &= 45,000 \text{ Watts} \\ \text{Stator copper loss} &= 1012 \text{ Watts, stator core loss} = 1200 \text{ Watts} \\ \text{Stator output} &= \text{Rotor input} = 42,788 \text{ Watts} \\ \text{Rotor copper loss} &= \text{Slip} \times \text{Rotor input} = 0.03 \times 42,788 = 1284 \text{ Watts} \\ \text{Rotor mech. output power} &= 42,788 - 1284 = 41,504 \text{ Watts} \\ \text{Shaft output} &= \text{Mech. output of rotor} - \text{Mech losses} \\ &= 41504 - 900 = 40604 \text{ Watts} \\ \text{Efficiency} &= \frac{40604}{45000} \times 100\% = 92.23\% \\ \text{Shaft output torque, } T &= \frac{40604 \times 60}{2\pi \times 970} = 400 \text{ Nw-m} \end{aligned}$$

**Example 34.39(a).** A 3-phase induction motor has a 4-pole, star-connected stator winding and runs on a 220-V, 50-Hz supply. The rotor resistance per phase is 0.1  $\Omega$  and reactance 0.9  $\Omega$ . The ratio of stator to rotor turns is 1.75. The full-load slip is 5%. Calculate for this load:

- (a) the load torque in kg-m
- (b) speed at maximum torque
- (c) rotor e.m.f. at maximum torque. (Electrical Machines-I, South Gujarat Univ. 1985)

**Solution.** (a)  $K = \text{rotor turns/stator turns} = 1/1.75$

stator voltage/phase,  $E_1 = 220/\sqrt{3}$  V

$\therefore$  standstill rotor e.m.f./phase,  $E_2 = K E_1 = \frac{220}{\sqrt{3}} \times \frac{1}{1.75} = 72.6 \text{ V}$

$$Z_r = \sqrt{R_2^2 + (sX_2^2)} = \sqrt{0.1^2 + (0.05 \times 0.9)^2} = 0.11 \Omega$$

$$I_2 = sE_2 / Z_r = 0.05 \times 72.6 / 0.11 = 33 \text{ A}$$

$$\text{Rotor Cu loss } P_{cr} = 3I_2^2 R_2 = 3 \times 33^2 \times 0.1 = 327 \text{ W}$$

$$\frac{\text{rotor Cu loss}}{\text{mech. power developed}} = \frac{s}{1-s}; \quad \frac{327}{P_m} = \frac{0.05}{1-0.05}; \quad P_m = 6213 \text{ W}$$

$$T_g = 9.55 P_m / N; \quad N = N_s (1-s) = 1500 (1-0.05) = 1425 \text{ rpm}$$

$$\therefore T_g = 9.55 \times 6213 / 1425 = 41.6 \text{ N-m} = 41.6 / 9.81 = \mathbf{4.24 \text{ kg.m}}$$

(b) For maximum torque,  $s_m = R_2 / X_2 = 0.1 / 0.81 = \mathbf{1/9}$

$$\therefore N = N_s (1-s) = 1500 (1 - 1/9) = \mathbf{1333 \text{ r.p.m.}}$$

(c) rotor e.m.f./phase at maximum torque =  $(1/9) \times 72.6 = \mathbf{8.07 \text{ V}}$

**Example 34.39 (b).** A 400 V, 3-phase, 50 Hz, 4-pole, star-connected induction-motor takes a line current of 10 A with 0.86 p. f. lagging. Its total stator losses are 5 % of the input. Rotor copper losses are 4 % of the input to the rotor, and mechanical losses are 3 % of the input of the rotor. Calculate (i) slip and rotor speed, (ii) torque developed in the rotor, and (iii) shaft-torque.

[Nagpur University, April 1998]

**Solution.** Input to motor =  $\sqrt{3} \times 400 \times 10 \times 0.86 = 5958 \text{ Watts}$

Total stator losses = 5% of 5958 = 298 Watts

Rotor input = Stator Output = 5958 – 298 = 5660 Watts

Rotor Copper-loss = 4 % of 5660 = 226.4 Watts

Mechanical losses = 3% of 5660 = 169.8 Watts

Shaft output = 5660 – 226.4 – 169.8 = 5264 Watts

(i) slip,  $s = \text{Rotor-copper-loss} / \text{rotor-input} = 4 \%$ , as given

Synchronous speed,  $N_s = 120 \times f / P = 1500 \text{ rpm}$

Rotor speed,  $N = N_s (1-s) = 1500 (1 - 0.04) = 1440 \text{ rpm}$

(ii) Let the torque developed in the rotor =  $T_r$

$\omega_r$  Angular speed of rotor =  $2\pi N / 60 = 150.72 \text{ radians/sec}$

Rotor output = Rotor input – Rotor-copper-loss

$$= 5660 - 226.4 = 5433.6 \text{ watts}$$

$$T_r \omega_r = 5433.6, \text{ giving } T_r = 5433.6 / 150.72 = 36.05 \text{ Nw-m}$$

(Alternatively, synchronous angular speed =  $\omega_s = 2\pi \times 1500 / 60 = 157 \text{ rad / sec}$

$$T_r \omega_s = \text{rotor input in Watts} = 5660$$

$$T_r = 5660 / 157 = 36.05 \text{ Nw - m}$$

(iii) Shaft-torque =  $T_m = \text{Shaft output in Watts} / \omega_r$

$$= 5264 / 150.72 = 34.93 \text{ Nw - m.}$$

**Example 34.40.** A 3-phase, 440-V, 50-Hz, 40-pole, Y-connected induction motor has rotor resistance of 0.1  $\Omega$  and reactance 0.9  $\Omega$  per phase. The ratio of stator to rotor turns is 3.5. Calculate:

- (a) gross output at a slip of 5%
- (b) the maximum torque in synchronous watts and the corresponding slip.

**Solution. (a)** Phase voltage =  $\frac{440}{\sqrt{3}} \text{ V}$ ;  $K = \frac{\text{rotor turns}}{\text{stator turns}} = \frac{1}{3.5}$

Standstill e.m.f. per rotor phase is  $E_2 = KE_1 = \frac{440}{\sqrt{3}} \times \frac{1}{3.5} = 72.6 \text{ V}$

$$E_r = s.E_2 = 0.05 \times 72.6 = 3.63 \text{ V}; Z_r = \sqrt{0.1^2 + (0.05 \times 0.9)^2} = 0.1096 \Omega$$

$$I_2 = \frac{E_r}{Z_r} = \frac{3.63}{0.1096} = 33.1 \text{ A}; \quad \text{Total Cu loss} = 3 I_2^2 R = 3 \times (33.1)^2 \times 0.1 = 330 \text{ W}$$

$$\frac{\text{rotor Cu loss}}{\text{rotor gross output}} = \frac{s}{1-s} \quad \therefore \text{rotor gross output} = \frac{330 \times 0.95}{0.05} = \mathbf{7,250 \text{ W}}$$

**(b) For Maximum Torque**

$$R_2 = s_m \cdot X_2 \quad \therefore s_m = R_2 / X_2 = 0.1/0.9 = \mathbf{1/9}; \quad E_r = (1/9) \times 72.6 = 8.07 \text{ V}$$

$$Z_r = \sqrt{0.1^2 + (0.9/9)^2} = 0.1414 \Omega; \quad I_2 = 8.07/0.1414 = 57.1 \text{ A}$$

$$\text{Total rotor Cu loss} = 3 \times 57.1^2 \times 0.1 = 978 \text{ W}$$

$$\text{rotor input} = \frac{\text{rotor Cu loss}}{s} = \frac{978}{1/9} = 8,802 \text{ W}$$

$\therefore$  Maximum torque in synchronous watts = rotor input = **8,802 W**

**Example 34.41.** An 18.65-kW, 4-pole, 50-Hz, 3-phase induction motor has friction and windage losses of 2.5 per cent of the output. The full-load slip is 4%. Compute for full load **(a)** the rotor Cu loss **(b)** the rotor input **(c)** the shaft torque **(d)** the gross electromagnetic torque.

**(Elect. Machines-II, Indore Univ. 1987)**

**Solution.** Motor output  $P_{out} = 18,650 \text{ W}$

Friction and windage loss  $P_w = 2.5\% \text{ of } 18,650 = 466 \text{ W}$

Rotor gross output  $P_m = 18,650 + 466 = 19,116 \text{ W}$

**(a)**  $\frac{\text{rotor Cu loss}}{\text{rotor gross output}} = \frac{s}{1-s}$ , rotor Cu loss =  $\frac{0.04}{(1-0.04)} \times 19,116 = \mathbf{796.6 \text{ W}}$

**(b)** Rotor input  $P_2 = \frac{\text{rotor Cu loss}}{s} = \frac{796.6}{0.04} = \mathbf{19,912.5 \text{ W}}$

(or rotor input = 19,116 + 796.6 = 19,913 W)

**(c)**  $T_{sh} = 9.55 P_{out} / N$ ;  $N_s = 120 \times 50/4 = 1500 \text{ r.p.m.}$

$$N = (1 - 0.04) \times 1500 = 1440 \text{ r.p.m.}$$

$\therefore$   $T_{sh} = 9.55 \times 18,650/1440 = \mathbf{123.7 \text{ N-m}}$

**(d)** Gross torque  $T_g = 9.55 P_m / N = 9.55 \times 19,116/1440 = \mathbf{126.8 \text{ N-m}}$

(or  $T_g = P_2 / 2 \pi N_s = 19,913/2 \pi \times 25 = 127 \text{ N-m}$ )

**Example 34.42.** An 8-pole, 3-phase, 50 Hz, induction motor is running at a speed of 710 rpm with an input power of 35 kW. The stator losses at this operating condition are known to be 1200 W while the rotational losses are 600 W. Find **(i)** the rotor copper loss, **(ii)** the gross torque developed, **(iii)** the gross mechanical power developed, **(iv)** the net torque and **(v)** the mechanical power output.

**(Elect. Engg. AMIETE Sec. A 1991 & Rajiv Gandhi Techn. Univ., Bhopal, 2000)**

**Solution.** **(i)**  $P_2 = 35 - 1.2 = 33.8 \text{ kW}$ ;  $N_s = 120 \times 50/8 = 750 \text{ rpm}$ ;  $N = 710 \text{ rpm}$ ;  $s = (750 - 710)/750 = 0.0533$

$\therefore$  Rotor Cu loss =  $sP_2 = \mathbf{1.8 \text{ kW}}$

**(ii)**  $P_m = P_2 - \text{rotor Cu loss} = 33.8 - 1.8 = \mathbf{32 \text{ kW}}$

**(iii)**  $T_g = 9.55 P_m / N = 9.55 \times 32000/710 = 430.42 \text{ N-m}$

**(iv)**  $P_{out} = P_m - \text{rotational losses} = 32000 - 600 = \mathbf{31400 \text{ W}}$

(v)  $T_{sh} = 9.55 P_{out} / N = 9.55 \times 31400 / 710 = 422.35 \text{ N-m}$

**Example 34.43.** A 6-pole, 50-Hz, 3-phase, induction motor running on full-load with 4% slip develops a torque of 149.3 N-m at its pulley rim. The friction and windage losses are 200 W and the stator Cu and iron losses equal 1,620 W. Calculate (a) output power (b) the rotor Cu loss and (c) the efficiency at full-load. (Elect. Technology, Mysore Univ. 1989)

**Solution.**  $N_s = 120 \times 50 / 6 = 1,000 \text{ r.p.m.}; N = (1 - 0.04) \times 1,000 = 960 \text{ r.p.m.}$

Out put power =  $T_{sh} \times 2 \pi N = 2 \pi \times (960/60) \times 149.3 = 15 \text{ kW}$

Now, output = 15,000 W

Friction and windage losses = 200 W ; Rotor gross output = 15,200 W

$\frac{P_m}{P_2} = \frac{N}{N_s} \therefore \text{rotor input } P_2 = 15,200 \times 1,000 / 960 = 15,833 \text{ W}$

(b)  $\therefore$  rotor Cu loss = 15,833 – 15,200 = 633 W

( rotor Cu loss is given by :  $\frac{\text{rotor Cu loss}}{\text{rotor output}} = \frac{s}{1-s}$  )

(c) stator output = rotor input = 15,833 W

Stator Cu and iron losses = 1,620 W

$\therefore$  Stator input  $P_1 = 15,833 + 1,620 = 17,453 \text{ W}$

overall efficiency,  $\eta = 15,000 \times 100 / 17,453 = 86\%$

**Example 34.44.** An 18.65-kW, 6-pole, 50-Hz, 3- $\phi$  slip-ring induction motor runs at 960 r.p.m. on full-load with a rotor current per phase of 35 A. Allowing 1 kW for mechanical losses, find the resistance per phase of 3-phase rotor winding. (Elect. Engg-I, Nagpur Univ. 1992)

**Solution.** Motor output = 18.65 kW; Mechanical losses = 1 kW

$\therefore$  Mechanical power developed by rotor,  $P_m = 18.65 + 1 = 19.65 \text{ kW}$

Now,  $N_s = 120 \times 50 / 6 = 1000 \text{ r.p.m.}; s = (1000 - 960) / 1000 = 0.04$

rotor Cu loss =  $\frac{s}{1-s} \times P_m = \frac{0.04}{(1-0.04)} \times 19.65 = 0.819 \text{ kW} = 819 \text{ W}$

$\therefore 3I_2^2 R_2 = 819 \text{ or } 3 \times 35^2 \times R_2 = 819 \quad R_2 = 0.023 \Omega / \text{phase}$

**Example 34.45.** A 400 V, 4-pole, 3-phase, 50-Hz induction motor has a rotor resistance and reactance per phase of 0.01  $\Omega$  and 0.1  $\Omega$  respectively. Determine (a) maximum torque in N-m and the corresponding slip (b) the full-load slip and power output in watts, if maximum torque is twice the full-load torque. The ratio of stator to rotor turns is 4.

**Solution.** Applied voltage/phase  $E_1 = 400 / \sqrt{3} = 231 \text{ V}$

Standstill e.m.f. induced in rotor,  $E_2 = KE_1 = 231 / 4 = 57.75 \text{ V}$

(a) Slip for maximum torque,  $s_m = R_2 / X_2 = 0.01 / 0.1 = 0.1$  or 10%

$T_{max} = \frac{3}{2\pi N_s} \times \frac{E_2^2}{2 X_2} \quad \dots \text{ Art. 34.20}$

$N_s = 120 \times 50 / 4 = 1500 \text{ r.p.m.} = 25 \text{ r.p.s.}$

$\therefore T_{max} = \frac{3}{2\pi \times 25} \times \frac{57.75^2}{2 \times 0.1} = 320 \text{ N-m}$

(b)  $\frac{T_f}{T} = \frac{2as_f}{a^2 + s^2} = \frac{1}{2}$ ; Now,  $a = R_2 / X_2 = 0.01 / 0.1 = 0.1$

$$\therefore 2 \times 0.1 \times s_f / (0.1^2 + s_f^2) = 1/2 \quad \therefore s_f = 0.027 \text{ or } 0.373$$

Since  $s_f = 0.373$  is not in the operating region of the motor, we select  $s_f = 0.027$ .

Hence,  $s_f = \mathbf{0.027}$ .  $N = 1500 (1 - 0.027) = 1459.5 \text{ r.p.m.}$

Full-load torque  $T_f = 320/2 = 160 \text{ N-m}$

F.L. Motor output  $= 2 \pi N T_f / 60 = 2 \pi \times 1459.5 \times 160 / 60 = \mathbf{24,454 \text{ W}}$

**Example 34.46.** A 3-phase induction motor has a 4-pole, Y-connected stator winding. The motor runs on 50-Hz supply with 200V between lines. The motor resistance and standstill reactance per phase are 0.1 Ω and 0.9 Ω respectively. Calculate

(a) the total torque at 4% slip (b) the maximum torque

(c) the speed at maximum torque if the ratio of the rotor to stator turns is 0.67. Neglect stator impedance. (Elect. Machinery, Mysore Univ. 1987)

**Solution. (a)** Voltage/phase  $= \frac{200}{\sqrt{3}} \text{ V}$ ;  $K = \frac{\text{rotor turns}}{\text{stator turns}} = 0.67$

Standstill rotor e.m.f. per phase is  $E_2 = \frac{200}{\sqrt{3}} \times 0.67 = 77.4 \text{ V}$  and  $s = 0.04$

$$Z_r = \sqrt{R_2^2 + (sX_2^2)} = \sqrt{0.1^2 + (0.04 \times 0.9)^2} = 0.106 \Omega$$

$$I_2 = \frac{sE_2}{Z_r} = \frac{77.4 \times 0.04}{0.106} = 29.1 \text{ A}$$

Total Cu loss in rotor  $= 3 I_2^2 R_2 = 3 \times 29.1^2 \times 0.1 = 255 \text{ W}$

Now,  $\frac{\text{rotor Cu loss}}{\text{rotor gross output}} = \frac{s}{1-s} \quad \therefore P_m = 255 \times 0.96 / 0.04 = 6,120 \text{ W}$

$N_s = 120 \times 50 / 4 = 1,500 \text{ r.p.m.}$ ;  $N = (1 - 0.04) \times 1,500 = 1440 \text{ r.p.m.}$

Gross torque developed,  $T_g = 9.55 P_m / N = 9.55 \times 6120 / 1440 = \mathbf{40.6 \text{ N-m}}$

(b) For maximum torque,  $s_m = R_2 / X_2 = 0.1 / 0.9 = 1/9$  and  $E_r = sE_2 = 77.4 \times 1/9 = 8.6 \text{ V}$

$$Z_r = \sqrt{0.1^2 + (0.9 \times 1/9)^2} = 0.1414 \Omega; \quad I_2 = 8.6 / 0.1414 = 60.8 \text{ A}$$

Total rotor Cu loss  $= 3 \times 60.8^2 \times 0.1 = 1,110 \text{ W}$

Rotor gross output  $= \frac{1,110 \times (1 - 1/9)}{1/9} = 8,800 \text{ W}$

$$N = (1 - 1/9) \times 1,500 = 1,333 \text{ rpm}$$

$\therefore T_{max} = 9.55 \times 8,800 / 1333 = \mathbf{63 \text{ N-m}}$

(c) Speed at maximum torque, as found above, is **1333.3 r.p.m.**

**Example 34.47.** The rotor resistance and standstill reactance of a 3-phase induction motor are respectively 0.015 Ω and 0.09 Ω per phase.

(i) What is the p.f. of the motor at start?

(ii) What is the p.f. at a slip of 4 percent ?

(iii) If the number of poles is 4, the supply frequency is 50-Hz and the standstill e.m.f. per rotor phase is 110 V, find out the full-load torque. Take full-load slip as 4 per cent.

(Electrical Technology-I, Osmania Univ. 1990)

**Solution. (i)** rotor impedance/phase  $= \sqrt{0.015^2 + 0.09^2} = 0.0912 \Omega$

p.f.  $= 0.015 / 0.0912 = \mathbf{0.164}$

(ii) reactance/phase  $= sX_2 = 0.04 \times 0.09 = 0.0036 \Omega$

$$\text{rotor impedance/phase} = \sqrt{0.015^2 + 0.0036^2} = 0.0154 \Omega$$

$$\text{p.f.} = 0.015/0.0154 = \mathbf{0.974}$$

$$\text{(iii)} \quad N_s = 120 \times 50/4 = 1,500 \text{ r.p.m.}; N = 1,500 - (0.04 \times 1,500) = 1,440 \text{ r.p.m.}$$

$$E_r = sE_2 = 0.04 \times 110 = 4.4 \text{ V}; Z_r = 0.0154 \Omega \quad \dots \text{found above}$$

$$I_2 = 4.4/0.0154 = 286 \text{ A}$$

$$\text{Total rotor Cu loss} = 3I_2^2 R_2 = 3 \times 286^2 \times 0.015 = 3,650 \text{ W}$$

$$\text{Now,} \quad \frac{\text{rotor Cu loss}}{\text{rotor gross output}} = \frac{s}{1-s}$$

$$\therefore \text{Rotor gross output } P_m = 3,650 \times 0.96/0.04 = 87,600 \text{ W}$$

If  $T_g$  is the gross torque developed by the rotor, then

$$T_g = 9.55 P_m / N = 9.55 \times 87,600/1440 = \mathbf{581 \text{ N-m}}$$

**Example 34.48.** The useful full load torque of 3-phase, 6-pole, 50-Hz induction motor is 162.84 N-m. The rotor e.m. f. is observed to make 90 cycles per minute. Calculate (a) motor output (b) Cu loss in rotor (c) motor input and (d) efficiency if mechanical torque lost in windage and friction is 20.36 N-m and stator losses are 830 W. (Elect. Machines-II, Indore Univ. 1988)

**Solution.**  $N_s = 120 \times 50/6 = 1,000 \text{ r.p.m.}$

Frequency of rotor e.m.f. = 90/60 = 1.5 Hz;  $s = f_r/f = 1.5/50 = 0.03$

Rotor speed = 1,000(1 - 0.03) = 970 r.p.m.; Useful F.L. torque = 162.84 N-m

$$\text{(a)} \quad \text{motor output} = T_{sh} \frac{2\pi N}{60} = \frac{2\pi \times 970 \times 162.84}{60} = \mathbf{16,540 \text{ W}}$$

$$\text{(b)} \quad \text{gross torque} \quad T_g = 162.84 + 20.36 = 183.2 \text{ N-m}$$

$$\text{Now,} \quad T_g = 9.55 \frac{P_2}{N_s} \quad \therefore 183.2 = 9.55 \times \frac{P_2}{1000}$$

$$\therefore \text{rotor input,} \quad P_2 = 183.2 \times 1000/9.55 = 19,170 \text{ W}$$

$$\therefore \text{rotor Cu loss} = s \times \text{rotor input} = 0.03 \times 19,170 = \mathbf{575.1 \text{ W}}$$

$$\text{(c)} \quad \text{Motor input,} \quad P_1 = 19,170 + 830 = \mathbf{20,000 \text{ W}}$$

$$\text{(d)} \quad \eta = (16,540/20,000) \times 100 = \mathbf{82.27\%}$$

**Example 34.49.** Estimate in kg-m the starting torque exerted by an 18.65-kW, 420-V, 6-pole, 50-Hz, 3-phase induction motor when an external resistance of 1  $\Omega$  is inserted in each rotor phase.

stator impedance : (0.25 + j 0.75)  $\Omega$

rotor impedance : (0.173 + j 0.52)  $\Omega$

stator/rotor voltage ratio: 420/350

connection: Star-Star

**Solution.**  $K = E_2/E_1 = 350/420 = 5/6$

Equivalent resistance of the motor as referred to rotor is

$$R_{02} = R_2 + K^2 R_1 = 0.173 + (5/6)^2 \times 0.25 = 0.346 \Omega / \text{phase}$$

Similarly,  $X_{02} = 0.52 + (5/6)^2 \times 0.75 = 1.04 \Omega / \text{phase}$

When an external resistance of 1 ohm/phase is added to the rotor circuit, the equivalent motor impedance as referred to rotor circuit is

$$Z_{02} = \sqrt{(1 + 0.346)^2 + 1.04^2} = 1.7 \Omega$$

$$\text{Short-circuit rotor current is } I_2 = \frac{350/\sqrt{3}}{1.7} = 119 \text{ A}$$

$$\text{Rotor Cu loss per phase on short-circuit} = 119^2 \times 1.173 = 16,610 \text{ W}$$

Now, rotor power input =  $\frac{\text{rotor Cu loss}}{s}$  ; On short-circuit,  $s = 1$   
 $\therefore$  rotor power input = rotor Cu loss on short-circuit  
 = 16,610 W/phase = 49,830 W for 3 phases  
 $N_s = 120 \times 50/6 = 1000$  r.p.m.

If  $T_{st}$  is the starting torque in newton-metres, then  
 $T_{st} = 9.55 P_2 / N_s = 9.55 \times 49,830/1000 = 476$  N-m =  $476/9.81 = 46.7$  kg-m.

**Example 34.50.** An 8-pole, 37.3-kW, 3-phase induction motor has both stator and rotor windings connected in star. The supply voltage is 280 V per phase at a frequency of 50 Hz. The short-circuit current is 200 A per phase at a short-circuit power factor of 0.25. The stator resistance per phase is 0.15 Ω. If transformation ratio between the stator and rotor windings is 3, find

- (i) the resistance per phase of the rotor winding
- (ii) the starting torque of the motor.

**Solution.** Under short circuit, all the power supplied to the motor is dissipated in the stator and rotor winding resistances. Short-circuit power supplied to the motor is

$$W_{sc} = 3 V_1 I_{sc} \cos \phi_{sc} = 3(280 \times 200 \times 0.25) \text{ W}$$

Power supplied/phase =  $280 \times 200 \times 0.25 = 14,000$  W

Let  $r_2'$  be the rotor resistance per phase as referred to stator. If  $r_1$  is the stator resistance per phase, then

$$I_{sc}^2 (r_1 + r_2') = 14,000 \quad \therefore r_1 + r_2' = 14,000 / 200^2 = 0.35 \Omega$$

$\therefore r_2' = 0.35 - 0.15 = 0.2 \Omega$  ; Now,  $r_2' = r_2 / K^2$  where  $K = 1/3$

(i)  $\therefore r_2 = K^2 r_2' = 0.2/9 = 0.022 \Omega$  per phase

(ii) Power supplied to the rotor circuit is  
 =  $3 I_{sc}^2 r_2' = 3 \times 200^2 \times 0.2 = 24,000$  W  
 $N_s = 120 \text{ } f/P = 120 \times 50/8 = 750$  r.p.m. = 12.5 r.p.s.

$\therefore$  Starting torque =  $9.55 P_2 / N_s = 9.55 \times 24,000/750 = 305.6$  N-m

**Example 34.51.** A 3-phase induction motor, at rated voltage and frequency has a starting torque of 160 per cent and a maximum torque of 200 per cent of full-load torque. Neglecting stator resistance and rotational losses and assuming constant rotor resistance, determine

- (a) the slip at full-load
- (b) the slip at maximum torque
- (c) the rotor current at starting in terms of F.L. rotor current.

(Electrical Machine - II, Bombay Univ. 1987)

**Solution.** As seen from Example 34.22 above,

- (a)  $s_f = 0.01$  or 1 %
- (b) From the same example it is seen that at maximum torque,  $a = s_b = 0.04$  or 4 %
- (c) As seen from Art. 34.40.

$$\frac{I_{2st}}{I_{2f}} = \sqrt{\frac{T_{st}}{s_f \cdot T_f}} = \sqrt{\frac{1.6}{0.01}} = 12.65$$

$\therefore$  Starting rotor current =  $12.65 \times$  F.L. rotor current

### 34.43. Sector Induction Motor

Consider a standard 3-phase, 4-pole, 50-Hz, Y-connected induction motor. Obviously, its  $N_s = 1500$  rpm. Suppose we cut the stator in half i.e. we remove half the stator winding with the result that only two complete  $N$  and  $S$  poles are left behind. Next, let us star the three phases without making any other changes in the existing connections. Finally, let us mount the original rotor above this **sector stator** leaving a small air-gap between the two. When this stator is energised from a 3-phase 50-Hz source, the rotor is found to run at almost 1500 rpm. In order to prevent saturation, the stator voltage should be reduced to half its original value because the sector stator winding has only half the original number of turns. It is found that under these conditions, this half-truncated sector motor still develops about 30% of its original rated power.

Fig. 34.41

The stator flux of the sector motor revolves at the same peripheral speed as the flux in the original motor. But instead of making a complete round, the flux in the sector motor simply travels **continuously from one end of the stator to the other**.

### 34.44. Linear Induction Motor

If, in a sector motor, the sector is laid out flat and a flat squirrel-cage winding is brought near to it, we get a linear induction motor (Fig. 34.42). In practice, instead of a flat squirrel-cage winding, an aluminium or copper or iron plate is used as a 'rotor'. The flat stator produces a flux that moves in a straight line from its one end to the other at a linear synchronous speed given by

where

$$v_s = 2 w f$$

$v_s$  = linear synchronous speed (m/s)  
 $w$  = width of one pole-pitch (m)  
 $f$  = supply frequency (Hz)

It is worth noting that speed **does not depend on the number of poles**, but only on the pole-pitch and stator supply frequency. As the flux moves linearly, it drags the rotor plate along with it in the **same direction**. However, in many practical applications, the 'rotor' is stationary, while the stator moves.

Fig. 34.42

For example, in high-speed trains, which utilize magnetic levitation (Art. 34.46), the rotor is composed of thick aluminium plate that is fixed to the ground and extends over the full length of the track. The linear stator is bolted to the undercarriage of the train.

### 34.45. Properties of a Linear Induction Motor

These properties are almost identical to those of a standard rotating machine.

1. **Synchronous speed.** It is given by  $v_s = 2 w f$

2. **Slip.** It is given by  $s = (v_s - v) / v_s$

where  $v$  is the actual speed.

3. **Thrust or Force.** It is given by  $F = P_2 / v_s$

where  $P_2$  is the active power supplied to the rotor.

4. **Active Power Flow.** It is similar to that in a rotating motor.

(i)  $P_{cr} = s P_2$  and

(ii)  $P_m = (1 - s) P_2$

**Example 34.52.** An electric train, driven by a linear motor, moves with 200 km/h, when stator frequency is 100 Hz. Assuming negligible slip, calculate the pole-pitch of the linear motor.

**Solution.**  $v_s = 2 \omega f$       $\omega = \frac{(200 \times 5/18)}{2 \times 100} = 277.8 \text{ mm}$

**Example 34.53.** An overhead crane in a factory is driven horizontally by means of two similar linear induction motors, whose 'rotors' are the two steel I-beams, on which the crane rolls. The 3-phase, 4-pole linear stators, which are mounted on opposite sides of the crane, have a pole-pitch of 6 mm and are energised by a variable-frequency electronic source. When one of the motors was tested, it yielded the following results:

Stator frequency = 25 Hz;     Power to stator = 6 kW  
 Stator Cu and iron loss = 1.2 kW;     crane speed = 2.4 m/s

Calculate (i) synchronous speed and slip (ii) power input to rotor (iii) Cu losses in the rotor (iv) gross mechanical power developed and (v) thrust.

**Solution. (i)**      $v_s = 2 \omega f = 2 \times 0.06 \times 25 = 3 \text{ m/s}$   
 $s = (v_s - v)/v_s = (3 - 2.4)/3 = 0.2$  or **20%**

**(ii)**      $P_2 = 6 - 1.2 = 4.8 \text{ kW}$

**(iii)**      $P_{cr} = sP_2 = 0.2 \times 4.8 = 0.96 \text{ kW}$

**(iv)**      $P_m = P_2 - P_{cr} = 4.8 - 0.96 = 3.84 \text{ kW}$

**(v)**      $F = P_2 / v_s = 4.8 \times 10^3 / 3 = 1600 \text{ N} = 1.60 \text{ kN}$

### 34.46. Magnetic Levitation

As shown in Fig. 34.43 (a), when a moving permanent magnet sweeps across a conducting ladder, it tends to drag the ladder along with, because it applies a horizontal tractive force  $F = BIl$ . It will now be shown that this horizontal force is also accompanied by a **vertical** force (particularly, at high magnet speeds), which tends to push the magnet away from the ladder in the upward direction.

Magnetic levitation

Fig. 34.43

A portion of the conducting ladder of Fig. 34.43 (a) has been shown in Fig. 34.43 (b). The voltage induced in conductor (or bar) A is maximum because flux is greatest at the centre of the N pole. If the magnet speed is very low, the induced current reaches its maximum value in A at virtually the **same time** (because delay due to conductor inductance is negligible). As this current flows via conductors B and C, it produces induced SSS and NNN poles, as shown. Consequently, the front half of

the magnet is pushed upwards while the rear half is pulled downwards. Since distribution of *SSS* and *NNN* pole is symmetrical with respect to the centre of the magnet, the vertical forces of attraction and repulsion, being equal and opposite, cancel each other out, leaving behind only horizontal tractive force.

Now, consider the case when the magnet sweeps over the conductor *A* with a *very high speed*, as shown in Fig. 34.44. Due to conductor inductance, current in *A* reaches its maximum value a fraction of a second ( $\Delta t$ ) after voltage reaches its maximum value. Hence, by the time *I* in conductor *A* reaches its maximum value, the centre of the magnet is already ahead of *A* by a distance =  $v \cdot \Delta t$  where  $v$  is the magnet velocity. The induced poles *SSS* and *NNN* are produced, as before, by the currents returning via conductors *B* and *C* respectively. But, by now, the *N* pole of the permanent magnet lies over the induced *NNN* pole, which pushes it upwards with a strong vertical force. \* This forms the basis of **magnetic levitation** which literally means 'floating in air'.

Fig. 34.44

Magnetic levitation is being used in ultrahigh speed trains (upto 300 km/h) which float in the air about 100 mm to 300 mm above the metallic track. They do not have any wheels and do not require the traditional steel rail. A powerful electromagnet (whose coils are cooled to about 4 °K by liquid helium) fixed underneath the train moves across the conducting rail, thereby inducing current in the rail. This gives rise to vertical force (called force of levitation) which keeps the train pushed up in the air above the track. Linear motors are used to propel the train.

A similar magnetic levitation system of transit is being considered for connecting Vivek Vihar in East Delhi to Viaspuri in West Delhi. The system popularly known as Magneto-Bahn (*M*-Bahn) completely eliminates the centuries-old 'steel-wheel-over steel rail' traction. The *M*-Bahn train floats in the air through the principle of magnetic levitation and propulsion is by linear induction motors. There is 50% decrease in the train weight and 60% reduction in energy consumption for propulsion purposes. The system is extraordinarily safe (even during an earthquake) and the operation is fully automatic and computer-based.

### Tutorial Problem No. 34.3

1. A 500-V, 50-Hz, 3-phase induction motor develops 14.92 kW inclusive of mechanical losses when running at 995 r.p.m., the power factor being 0.87. Calculate (a) the slip (b) the rotor Cu losses (c) total input if the stator losses are 1,500 W (d) line current (e) number of cycles per minute of the rotor e.m.f. **[(a) 0.005 (b) 75 W (c) 16.5 kW (d) 22 A (e) 15] (City & Guilds, London)**
2. The power input to a 3-phase induction motor is 40 kW. The stator losses total 1 kW and the friction and winding losses total 2 kW. If the slip of the motor is 4%, find (a) the mechanical power output (b) the rotor Cu loss per phase and (c) the efficiency. **[(a) 37.74 kW (b) 0.42 kW (c) 89.4%]**
3. The rotor e.m.f. of a 3-phase, 440-V, 4-pole, 50-Hz induction motor makes 84 complete cycles per minute when the shaft torque is 203.5 newton-metres. Calculate the h.p. of the motor. **[41.6 h.p. (31.03 kW)] (City & Guilds, London)**
4. The input to a 3-phase induction motor, is 65 kW and the stator loss is 1 kW. Find the total mechanical power developed and the rotor copper loss per phase if the slip is 3%. Calculate also in

\* The induced current is always delayed (even at low magnet speeds) by an interval of time  $\Delta t$  which depends on the  $L/R$  time-constant of the conductor circuit. This delay is so brief at slow speed that voltage and the current reach their maximum value virtually at the same *time* and *place*. But at high speed, the same delay  $\Delta t$  is sufficient to produce large shift *in space* between the points where the voltage and current achieve their maximum values.

- terms of the mechanical power developed the input to the rotor when the motor yields full-load torque at half speed. **[83.2 h.p. (62.067 kW) : 640 W, Double the output] (City & Guilds. London)**
5. A 6-pole, 50-Hz, 8-phase induction motor, running on full-load, develops a useful torque of 162 N-m and it is observed that the rotor electromotive force makes 90 complete cycles per min. Calculate the shaft output. If the mechanical torque lost in friction be 13.5 Nm, find the copper loss in the rotor windings, the input to the motor and the efficiency. Stator losses total 750 W.  
**[16.49 kW; 550 W; 19.2 kW; 86%]**
  6. The power input to a 500-V, 50-Hz, 6-pole, 3-phase induction motor running at 975 rpm is 40 kW. The stator losses are 1 kW and the friction and windage losses total 2 kW. Calculate (a) the slip (b) the rotor copper loss (c) shaft output (d) the efficiency. **[(a) 0.025 (b) 975 W (c) 36.1 kW (d) 90%]**
  7. A 6-pole, 3-phase induction motor develops a power of 22.38kW, including mechanical losses which total 1.492 kW at a speed of 950 rpm on 550-V, 50-Hz mains. The power factor is 0.88. Calculate for this load (a) the slip (b) the rotor copper loss (c) the total input if the stator losses are 2000 W (d) the efficiency (e) the line current (f) the number of complete cycles of the rotor electromotive force per minute. **[(a) 0.05 (b) 1175 (c) 25.6 kW (d) 82% (e) 30.4 A (f) 150]**
  8. A 3-phase induction motor has a 4-pole, star-connected stator winding. The motor runs on a 50-Hz supply with 200 V between lines. The rotor resistance and standstill reactance per phase are 0.1  $\Omega$  and 0.9  $\Omega$  respectively. The ratio of rotor to stator turns is 0.67. Calculate (a) total torque at 4% slip (b) total mechanical power at 4% slip (c) maximum torque (d) speed at maximum torque (e) maximum mechanical power. Prove the formulae employed, neglecting stator impedance.  
**[(a) 40 Nm (b) 6 kW (c) 63.7 Nm (d) 1335 rpm (e) 8.952 kW.]**
  9. A 3-phase induction motor has a 4-pole, star-connected, stator winding and runs on a 220-V, 50-Hz supply. The rotor resistance is 0.1  $\Omega$  and reactance 0.9. The ratio of stator to rotor turns is 1.75. The full load slip is 5%. Calculate for this load (a) the total torque (b) the shaft output. Find also (c) the maximum torque (d) the speed at maximum torque.  
**[(a) 42 Nm (b) 6.266 kW (c) 56 Nm (d) 1330 rpm ]**
  10. A 3000-V, 24-pole, 50-Hz 3-phase, star-connected induction motor has a slip-ring rotor of resistance 0.016  $\Omega$  and standstill reactance 0.265  $\Omega$  per phase. Full-load torque is obtained at a speed of 247 rpm. Calculate (a) the ratio of maximum to full-load torque (b) the speed at maximum torque. Neglect stator impedance. **[(a) 2.61 (b) 235 rpm ]**
  11. The rotor resistance and standstill reactance of a 3-phase induction motor are respectively 0.015  $\Omega$  and 0.09  $\Omega$  per phase. At normal voltage, the full-load slip is 3%. Estimate the percentage reduction in stator voltage to develop full-load torque at one-half of full-load speed. What is then the power factor ? **[22.5%; 0.31 ]**
  12. The power input to a 3-phase, 50-Hz induction motor is 60 kW. The total stator loss is 1000 W. Find the total mechanical power developed and rotor copper loss if it is observed that the rotor e.m.f. makes 120 complete cycles per minute.  
**[56.64 kW; 2.36 kW] (AMIE Sec. B Elect. Machine (E-3) Summer 1990)**
  13. A balanced three phase induction motor has an efficiency of 0.85 when its output is 44.76 kW. At this load both the stator copper loss and the rotor copper loss are equal to the core losses. The mechanical losses are one-fourth of the no-load loss. Calculate the slip.  
**[4.94%] (AMIE Sec. B Elect. Machines (E-3) Winter 1991)**
  14. An induction motor is running at 20% slip, the output is 36.775 kW and the total mechanical losses are 1500 W. Estimate Cu losses in the rotor circuit. If the stator losses are 3 kW, estimate efficiency of the motor. **[9,569 W, 72.35%] (Electrical Engineering-II, Bombay Univ. 1978)**
  15. A 3- $\phi$ , 50-Hz, 500-V, 6-pole induction motor gives an output of 37.3 kW at 955 r.p.m. The power factor is 0.86, frictional and windage losses total 1.492 kW; stator losses amount to 1.5 kW. Determine (i) line current (ii) the rotor Cu loss for this load.  
**[(i) 56.54 A (ii) 88.6% (iii) 1.828 kW] (Electrical Technology, Kerala Univ. 1977)**
  16. Determine the efficiency and the output horse-power of a 3-phase, 400-V induction motor running

on load with a slip of 4 per cent and taking a current of 50 A at a power factor of 0.86. When running light at 400 V, the motor has an input current of 15 A and the power taken is 2,000 W, of which 650 W represent the friction, windage and rotor core loss. The resistance per phase of the stator winding (delta-connected) is 0.5 Ω.

[85.8 per cent; 34.2 h.p. (25.51 kW)] (Electrical Engineering-II, M.S. Univ. Baroda 1977)

17. The power input to the rotor of a 440-V, 50-Hz, 3-phase, 6-pole induction motor is 60 kW. It is observed that the rotor e.m.f. makes 90 complete cycles per minute. Calculate (a) the slip (b) rotor speed (c) rotor Cu loss per phase (c) the mechanical power developed and (e) the rotor resistance per phase if rotor current is 60 A. [(a) 0.03 (b) 970 r.p.m. (c) 600 W (d) 58.2 kW (e) 0.167 Ω]
18. An induction motor is running at 50% of the synchronous speed with a useful output of 41.03 kW and the mechanical losses total 1.492 kW. Estimate the Cu loss in the rotor circuit of the motor. If the stator losses total 3.5 kW, at what efficiency is the motor working? [42.52 kW; 46.34%] (Electrical Engineering-II, Bombay Univ. 1975)
19. Plot the torque/speed curve of a 6-pole, 50-Hz, 3-phase induction motor. The rotor resistance and reactance per phase are 0.02 Ω and 0.1 Ω respectively. At what speed is the torque a maximum? What must be the value of the external rotor resistance per phase to give two-third of maximum torque at starting? [(a) 800 rpm (b) 0.242 Ω or 0.018 Ω]

### 34.47. Induction Motor as a Generalized Transformer

The transfer of energy from stator to the rotor of an induction motor takes place entirely *inductively*, with the help of a flux mutually linking the two. Hence, an induction motor is essentially a transformer with stator forming the primary and rotor forming (the short-circuited) rotating secondary (Fig. 34.45). The vector diagram is similar to that of a transformer (Art. 32.15).

Fig. 34.45

In the vector diagram of Fig. 34.46,  $V_1$  is the applied voltage per stator phase,  $R_1$  and  $X_1$  are stator resistance and leakage reactance per phase respectively, shown external to the stator winding in Fig. 34.45. The applied voltage  $V_1$  produces a magnetic flux which links both primary and secondary thereby producing a counter e.m.f. of self-induction  $E_1$  in primary (i.e. stator) and a mutually-induced e.m.f.  $E_r (= sE_2)$  in secondary (i.e. rotor). There is no secondary terminal voltage  $V_2$  in secondary because whole of the induced e.m.f.  $E_r$  is used up in circulating the rotor current as the rotor is closed upon itself (which is equivalent to its being short-circuited).

Obviously 
$$\mathbf{V}_1 = \mathbf{E}_1 + I_1 R_1 + j I_1 X_1$$

The magnitude of  $E_r$  depends on voltage transformation ratio  $K$  between stator and rotor and the slip. As it is wholly absorbed in the rotor impedance.

∴ 
$$\mathbf{E}_r = \mathbf{I}_2 \mathbf{Z}_2 = I_2 (R_2 + j s X_2)$$

In the vector diagram,  $I_0$  is the no-load primary current. It has two components (i) the working or iron loss components  $I_w$  which supplies the no-load motor losses and (ii) the magnetising component  $I_\mu$  which sets up magnetic flux in the core and the air-gap.

Fig. 34.46

Obviously  $I_0 = \sqrt{(I_{\omega}^2 + I_{\mu}^2)}$  Fig. 34.45,  $I_{\omega}$  and  $I_{\mu}$  are taken care of by an exciting circuit containing  $R_0 = E_1/I_{\omega}$  and  $X_0 = E_1/I_{\mu}$  respectively.

It should be noted here, in passing that in the usual two-winding transformer,  $I_0$  is quite small (about 1% of the full-load current). The reason is that the magnetic flux path lies almost completely in the steel core of low reluctance, hence  $I_{\mu}$  is small, with the result that  $I_0$  is small. But in an induction motor, the presence of an air-gap (of high reluctance) necessitates a large  $I_{\mu}$  hence  $I_0$  is very large (approximately 40 to 50% of the full-load current).

In the vector diagram,  $I_2'$  is the equivalent load current in primary and is equal to  $KI_2$ . Total primary current is the **vector** sum of  $I_0$  and  $I_2'$ .

At this place, a few words may be said to justify the representation of the stator and rotor quantities on the same vector diagram, even though the frequency of rotor current and e.m.f. is only a fraction of that of the stator. We will now show that even though the frequencies of stator and rotor currents are different, yet magnetic fields due to them are synchronous with each other, when seen by an observer stationed in space—both fields rotate at synchronous speed  $N_s$  (Art. 34.11).

The current flowing in the short-circuited rotor produces a magnetic field, which revolves round the rotor in the same direction as the stator field. The speed of rotation of the rotor field is

$$= \frac{120 f_r}{P} = \frac{120 sf}{P} = sN_s = N_s \times \frac{N_s - N}{N_s} = (N_s - N)$$

Rotor speed  $N = (1 - s) N_s$

Hence, speed of the rotating field of the rotor with respect to the stationary stator or space is

$$= sN_s + N = (N_s - N) + N = N_s$$

### 34.48. Rotor Output

Primary current  $I_1$  consists of two parts,  $I_0$  and  $I_2'$ . It is the latter which is transferred to the rotor, because  $I_0$  is used in meeting the Cu and iron losses in the stator itself. Out of the applied primary voltage  $V_1$ , some is absorbed in the primary itself ( $= I_1 Z_1$ ) and the remaining  $E_1$  is transferred to the rotor. If the angle between  $E_1$  and  $I_2'$  is  $\phi$ , then

Rotor input / phase =  $E_1 I_2' \cos \phi$ ; Total rotor input =  $3E_1 I_2' \cos \phi$

The electrical input to the rotor which is wasted in the form of heat is

$$= 3I_2 E_r \cos \phi \quad (\text{or } = 3 I_2^2 R_2)$$

Now  $I_2' = KI_2$  or  $I_2 = I_2' / K$

$$E_r = s E_2 \quad \text{or} \quad E_2 = KE_1$$

$\therefore E_r = sKE_1$

$\therefore$  electrical input wasted as heat

$$= 3 \times (I_2' / K) \times sK E_1 \times \cos \phi = 3E_1 I_2' \cos \phi \times s = \text{rotor input} \times s$$

Now, rotor output = rotor input – losses =  $3E_1 I_2' \cos \phi - 3E_1 I_2' \cos \phi \times s$

$$= (1 - s) 3E_1 I_2' \cos \phi = (1 - s) \times \text{rotor input}$$

$\therefore \frac{\text{rotor output}}{\text{rotor input}} = 1 - s \quad \therefore \text{rotor Cu loss} = s \times \text{rotor input}$

$$\text{rotor efficiency} = 1 - s = \frac{N}{N_s} = \frac{\text{actual speed}}{\text{synchronous speed}}$$

In the same way, other relation similar to those derived in Art. 34.37 can be found.

### 34.49. Equivalent Circuit of the Rotor

When motor is loaded, the rotor current  $I_2$  is given by

$$I_2 = s \frac{E_2}{\sqrt{[R_2^2 + (sX_2)^2]}} = \frac{E_2}{\sqrt{[(R_2/s)^2 + X_2^2]}}$$

From the above relation it appears that the rotor circuit which actually consists of a fixed resistance  $R_2$  and a variable reactance  $sX_2$  (proportional to slip) connected across  $E_r = sE_2$  [Fig. 34.47 (a)] can be looked upon as equivalent to a rotor circuit having a fixed reactance  $X_2$  connected in series with a variable resistance  $R_2/s$  (inversely proportional to slip) and supplied with constant voltage  $E_2$ , as shown in Fig. 34.47 (b).

Fig. 34.47

Fig. 34.48

Now, the resistance  $\frac{R_2}{s} = R_2 + R_2 \left(\frac{1}{s} - 1\right)$ . It consists of two parts :

- (i) the first part  $R_2$  is the rotor resistance itself and represents the rotor Cu loss.
- (ii) the second part is  $R_2 \left(\frac{1}{s} - 1\right)$

This is known as the load resistance  $R_L$  and is the electrical equivalent of the mechanical load on the motor. In other words, the mechanical load on an induction motor can be represented by a non-inductive resistance of the value  $R_2 \left(\frac{1}{s} - 1\right)$ . The equivalent rotor circuit along with the load resistance  $R_L$  may be drawn as in Fig. 34.48.

### 34.50. Equivalent Circuit of an Induction Motor

As in the case of a transformer (Fig. 32.14), in this case also, the secondary values may be transferred to the primary and *vice versa*. As before, it should be remembered that when shifting impedance or resistance from secondary to primary, it should be **divided** by  $K^2$  whereas current should be **multiplied** by  $K$ . The equivalent circuit of an induction motor where all values have been referred to primary *i.e.* stator is shown in Fig. 34.49.

Fig. 34.49

As shown in Fig. 34.50, the exciting circuit may be transferred to the left, because inaccuracy involved is negligible but the circuit and hence the calculations are very much simplified. This is

known as the **approximate equivalent** circuit of the induction motor.

If transformation ratio is assumed unity i.e.  $E_2/E_1 = 1$ , then the equivalent circuit is as shown in Fig. 34.51 instead of that in Fig. 34.49.

Fig. 34.50

Fig. 34.51

### 34.51. Power Balance Equations

With reference to Fig. 34.49 (a), following power relations in an induction motor can be deduced:

Input power =  $3 V_1 I_1 \cos \phi_1$ ; stator core loss =  $I_w^2 R_0$ ; stator Cu loss =  $3 I_1^2 R_1$

Power transferred to rotor =  $3 I_2'^2 R_2'/s$ ; Rotor Cu loss =  $3 I_2'^2 R_2'$

Mechanical power developed by rotor ( $P_m$ ) or gross power developed by rotor ( $P_g$ ) = rotor input – rotor Cu losses

$$= 3 I_2'^2 R_2' / s - 3 I_2'^2 R_2' = 3 I_2'^2 R_2' \left( \frac{1-s}{s} \right) \text{ Watt}$$

If  $T_g$  is the gross torque\* developed by the rotor, then

$$T_g \times \omega = T_g \times 2\pi \frac{N}{60} = 3 I_2'^2 R_2' \left( \frac{1-s}{s} \right)$$

$$\therefore T_g = \frac{3 I_2'^2 R_2' \left( \frac{1-s}{s} \right)}{2\pi N / 60} \text{ N-m}$$

Now,

$N = N_s(1 - s)$ . Hence gross torque becomes

$$T_g = \frac{3 I_2'^2 R_2' / s}{2\pi N_s / 60} \text{ N-m} = 9.55 \times \frac{3 I_2'^2 R_2' / s}{N_s} \text{ N-m}$$

Since gross torque in **synchronous watts** is equal to the power transferred to the rotor across the air-gap.

$$\therefore T_g = 3 I_2'^2 R_2' / s \text{ synch. watt.}$$

It is seen from the approximate circuit of Fig. 34.50 that

$$I_2' = \frac{V_1}{(R_1 + R_2'/s) + j(X_1 + X_2')}$$

$$T_g = \frac{3}{2\pi N_s / 60} \times \frac{V_1^2}{(R_1 + R_2'/s)^2 + (X_1 + X_2')^2} \times \frac{R_2'}{s} \text{ N-m}$$

\* It is different from shaft torque, which is less than  $T_g$  by the torque required to meet windage and frictional losses.

### 34.52. Maximum Power Output

Fig. 34.52 shows the approximate equivalent circuit of an induction motor with the simplification that :

- (i) exciting circuit is omitted i.e.  $I_0$  is neglected and
- (ii)  $K$  is assumed unity.

As seen, gross power output for 3-phase induction motor is

$$P_g = 3 I_1^2 R_L$$

Now, 
$$I_1 = \frac{V_1}{\sqrt{[(R_{01} + R_L)^2 + X_{01}^2]}} \quad \therefore P_g = \frac{3 V_1^2 R_L}{(R_{01} + R_L)^2 + X_{01}^2}$$

The condition for maximum power output can be found by differentiating the above equation and by equating the first derivative to zero. If it is done, it will be found that

$$R_L^2 = R_{01}^2 + X_{01}^2 = Z_{01}^2$$

where  $Z_{01}$  = leakage impedance of the motor as referred to primary

$$\therefore R_L = Z_{01}$$

Hence, the power output is maximum **when the equivalent load resistance is equal to the stand-still leakage impedance of the motor.**

Fig. 34.52

### 34.53. Corresponding Slip

Now  $R_L = R_2 [(1/s) - 1] \quad \therefore Z_{01} = R_L = R_2 [(1/s) - 1] \text{ or } s = \frac{R_2}{R_2 + Z_{01}}$

This is the slip corresponding to maximum gross power output. The value of  $P_{gmax}$  is obtained by substituting  $R_L$  by  $Z_{01}$  in the above equation.

$$\therefore P_{gmax} = \frac{3 V_1^2 Z_{01}}{(R_{01} + Z_{01})^2 + X_{01}^2} = \frac{3 V_1^2 Z_{01}}{R_{01}^2 + Z_{01}^2 + 2 R_{01} Z_{01} + X_{01}^2} = \frac{3 V_1^2}{2 (R_{01} + Z_{01})}$$

It should be noted that  $V_1$  is voltage/phase of the motor and  $K$  has been taken as unity.

**Example 34.54.** The maximum torque of a 3-phase induction motor occurs at a slip of 12%. The motor has an equivalent secondary resistance of 0.08  $\Omega$ /phase. Calculate the equivalent load resistance  $R_L$ , the equivalent load voltage  $V_L$  and the current at this slip if the gross power output is 9,000 watts.

**Solution.**  $R_L = R_2 [(1/s) - 1] = 0.08 [(1/0.12) - 1] = 0.587 \Omega$  /phase.

As shown in the equivalent circuit of the rotor in Fig. 34.53,  $V$  is a fictitious voltage drop equivalent to that consumed in the load connected to the secondary i.e. rotor. The value of  $V = I_2 R_L$

Now, gross power  $P_g = 3 I_2^2 R_L = 3 V^2 / R_L$

$$V = \sqrt{(P_g \times R_L / 3)} = \sqrt{(0.587 \times 9000 / 3)} = 42 \text{ V}$$

Equivalent load current =  $V / R_L = 42 / 0.587 = 71.6 \text{ A}$

Fig. 34.53

**Example 34.55.** A 3-phase, star-connected 400 V, 50-Hz, 4-pole induction motor has the following per phase parameters in ohms, referred to the stators.

$$R_1 = 0.15, X_1 = 0.45, R_2' = 0.12, X_2' = 0.45, X_m = 28.5$$

Compute the stator current and power factor when the motor is operated at rated voltage and frequency with  $s = 0.04$ . **(Elect. Machines, A.M.I.E. Sec. B, 1990)**

**Solution.** The equivalent circuit with all values referred to stator is shown in Fig. 34.54.

$$R_L' = R_2' \left( \frac{1}{s} - 1 \right)$$

$$= 0.12 \left( \frac{1}{0.04} - 1 \right) = 2.88 \Omega$$

$$I_2' = \frac{V}{(R_{01} + R_L') + j X_{01}}$$

$$= \frac{400/\sqrt{3}}{(0.15 + 0.12 + 2.88) + j(0.45 + 0.45)}$$

$$= 67.78 - j 19.36$$

$$I_0 = \frac{400/\sqrt{3}}{X_m} = \frac{400}{\sqrt{3} \times j 28.5} = -j 8.1$$

Fig. 34.54

Stator current,  $I_1 = I_0 + I_2' = 67.78 - j 19.36 - j 8.1 = 73.13 \angle - 22^\circ$   
 p.f. =  $\cos \phi = \cos 22^\circ = 0.927$  (lag)

**Example 34.56.** A 220-V, 3- $\phi$ , 4-pole, 50-Hz, Y-connected induction motor is rated 3.73 kW. The equivalent circuit parameters are:

$$R_1 = 0.45 \Omega, X_1 = 0.8 \Omega; R_2' = 0.4 \Omega, X_2' = 0.8 \Omega, B_0 = -1/30 \text{ mho}$$

The stator core loss is 50 W and rotational loss is 150 W. For a slip of 0.04, find (i) input current (ii) p.f. (iii) air-gap power (iv) mechanical power (v) electro-magnetic torque (vi) output power and (vii) efficiency.

**Solution.** The exact equivalent circuit is shown in Fig. 34.55. Since  $R_0$  (or  $G_0$ ) is negligible in determining  $I_1$ , we will consider  $B_0$  (or  $X_0$ ) only

$$Z_{AB} = \frac{j X_m [(R_2'/s) + j X_2']}{(R_2'/s) + j (X_2' + X_m)} = \frac{j 30 (10 + j 0.8)}{10 + j 30.8} = 8.58 + j 3.56 = 9.29 \angle 22.5^\circ$$

$$Z_{01} = Z_1 + Z_{AB} = (0.45 + j 0.8) + (8.58 + j 3.56) = 9.03 + j 4.36 = 10 \angle 25.8^\circ$$

$$V_{ph} = \frac{220}{\sqrt{3}} \angle 0^\circ = 127 \angle 0^\circ$$

(i)  $\therefore I_1 = V_1 / Z_{01} = 127 \angle 0^\circ / 10 \angle 25.8^\circ = 12.7 \angle - 25.8^\circ \text{ A}$

(ii) p.f. =  $\cos 25.8^\circ = 0.9$

(iii) air-gap power,  $P_2 = 3 I_2'^2 (R_2'/s) = 3 I_1^2 R_{AB}$   
 $= 3 \times 12.7^2 \times 8.58 = 4152 \text{ W}$

(iv)  $P_m = (1 - s) P_2 = 0.96 \times 4152 = 3,986 \text{ W}$

(v) Electromagnetic torque (i.e. gross torque)

$$T_g = \frac{P_m}{2\pi N / 60} = 9.55 \frac{P_m}{N} \text{ N-m}$$

Now,  $N_s = 1500 \text{ r.p.m.}, N = 1500 (1 - 0.04) = 1440 \text{ r.p.m.}$

Fig. 34.55

$$T_g = 9.55 \times 3986/1440 = \mathbf{26.4 \text{ N-m}}$$

$$\text{(or } T_g = 9.55 \frac{P_2}{N_s} = 9.55 \times \frac{4152}{1500} = \mathbf{26.4 \text{ N-m}}$$

(vi) output power = 3986 – 150 = **3836 W**

(vii) stator core loss = 50 W; stator Cu loss =  $3 I_1^2 R_1 = 3 \times 12.7^2 \times 0.45 = 218 \text{ W}$

Rotor Cu loss =  $3 I_2'^2 R_2' = sP_2 = 0.04 \times 4152 = 166 \text{ W}$ ; Rotational losses = 150 W

Total loss = 50 + 218 + 166 + 150 = 584 W;  $\eta = 3836/(3836 + 584) = 0.868$  or **86.8%**

**Example 34.57.** A 440-V, 3- $\phi$  50-Hz, 37.3 kW, Y-connected induction motor has the following parameters:

$$R_1 = 0.1 \Omega, X_1 = 0.4 \Omega, R_2' = 0.15 \Omega, X_2' = 0.44 \Omega$$

Motor has stator core loss of 1250 W and rotational loss of 1000 W. It draws a no-load line current of 20 A at a p.f. of 0.09 (lag). When motor operates at a slip of 3%, calculate (i) input line current and p.f. (ii) electromagnetic torque developed in N-m (iii) output and (iv) efficiency of the motor. **(Elect. Machines -II, Nagpur Univ. 1992)**

**Solution.** The equivalent circuit of the motor is shown in Fig. 34.49 (a). Applied voltage per phase =  $440/\sqrt{3} = 254 \text{ V}$ .

$$I_2' = \frac{V_1}{(R_1 + R_2'/s) + j(X_1 + X_2')} = \frac{254 \angle 0^\circ}{(0.1 + 0.15/0.03) + j(0.4 + 0.44)}$$

$$= \frac{254 \angle 0^\circ}{5.1 + j0.84} = \frac{254 \angle 0^\circ}{5.17 \angle 9.3^\circ} = 49.1 \angle -9.3^\circ = 48.4 - j7.9$$

For all practical purposes, no-load motor current may be taken as equal to magnetising current  $I_0$ . Hence,  $I_0 = 20 \angle -84.9^\circ = 1.78 - j19.9$ .

(i)  $I_1 = I_0 + I_2' = (1.78 - j19.9) + (48.4 - j7.9) = 50.2 - j27.8 = \mathbf{57.4 \angle -29^\circ}$

$\therefore$  p.f. =  $\cos 29^\circ = \mathbf{0.875 \text{ (lag)}}$ .

(ii)  $P_2 = 3 I_2'^2 (R_2'/s) = 3 \times 49.1^2 \times (0.15/0.03) = 36,160 \text{ W}$

$N_s = 1500 \text{ r.p.m.}$

$\therefore T_g = 9.55 \times 36,160/1500 = \mathbf{230 \text{ N-m}}$

(iii)  $P_m = (1 - s) P_2 = 0.97 \times 36,160 = 35,075 \text{ W}$

Output power = 35,075 – 1000 = **34,075 W**

Obviously, motor is delivering less than its rated output at this slip.

(iv) Let us total up the losses.

Core loss = 1250 W, stator Cu loss =  $3 I_1^2 R_1 = 3 \times 57.4^2 \times 0.1 = 988 \text{ W}$

Rotor Cu loss =  $3 I_2'^2 R_2' = sP_2 = 0.03 \times 36,160 = 1085 \text{ W}$

rotational i.e. friction and windage losses = 1000 W

Total losses = 1250 + 988 + 1085 + 1000 = 4323 W

$\eta = 34,075/(34,075 + 4323) = 0.887$  or **88.7%**

or input =  $\sqrt{3} \times 440 \times 57.4 \times 0.875 = 38,275 \text{ W}$

$\therefore \eta = 1 - (4323/38,275) = 0.887$  or **88.7%**

**Example 34.58.** A 400 V, 3- $\phi$ , star-connected induction motor has a stator exciting impedance of  $(0.06 + j 0.2) \Omega$  and an equivalent rotor impedance of  $(0.06 + j 0.22) \Omega$ . Neglecting exciting current, find the maximum gross power and the slip at which it occurs. **(Elect. Engg.-II, Bombay Univ. 1987)**

**Solution.** The equivalent circuit is shown in Fig. 34.56.

$$R_{01} = R_1 + R_2' = 0.06 + 0.06 = 0.12 \Omega$$

$$X_{01} = X_1 + X_2' = 0.2 + 0.22 = 0.42 \Omega$$

$$\therefore Z_{01} = \sqrt{(0.12^2 + 0.42^2)} = 0.44 \Omega$$

As shown in Art. 34.53, slip corresponding to maximum gross power output is given by

$$s = \frac{R_2}{R_2 + Z_{01}} = \frac{0.06}{0.06 + 0.44} = 0.12 \text{ or } 12\%$$

Voltage/phase,  $V_1 = 400/\sqrt{3} \text{ V}$

$$P_{g \max} = \frac{3V_1^2}{2(R_{01} + Z_{01})} = \frac{3(400/\sqrt{3})^2}{2(0.12 + 0.44)} = 142,900 \text{ W.}$$

Fig. 34.56

**Example 34.59.** A 115V, 60-Hz, 3-phase, Y-Connected, 6-pole induction motor has an equivalent T-circuit consisting of stator impedance of  $(0.07 + j 0.3) \Omega$  and an equivalent rotor impedance at standstill of  $(0.08 + j 0.3) \Omega$ . Magnetising branch has  $G_o = 0.022 \text{ mho}$ ,  $B_o = 0.158 \text{ mho}$ . Find (a) secondary current (b) primary current (c) primary p.f. (d) gross power output (e) gross torque (f) input (g) gross efficiency by using approximate equivalent circuit. Assume a slip of 2% .

**Solution.** The equivalent circuit is shown in Fig. 34.57  $R_L' = R_2' [(1/s) - 1]$

$$= 0.88 \left( \frac{1}{0.02} - 1 \right) = 3.92 \Omega / \text{phase}$$

The impedance to the right of terminals c and d is

$$\begin{aligned} Z_{cd} &= R_{01} + R_L' + j X_{01} \\ &= (0.07 + 0.08) + 3.92 + j 0.6 \\ &= 4.07 + j 0.6 \\ &= 4.11 \angle 8.4^\circ \Omega / \text{phase} \end{aligned}$$

$$V = 115/\sqrt{3} = 66.5 \text{ V}$$

(a) Secondary current  $I_2' = I_2$

$$= \frac{66.5}{4.11 \angle 8.4^\circ} = 16.17 \angle -j 8.4^\circ$$

$$= 16 - j 2.36 \text{ A}$$

The exciting current  $I_0 = V(G_o - j B_o) = 66.5 (0.022 - j 0.158) = 1.46 - j 10.5 \text{ A}$

(b)  $I_1 = I_0 + I_2' = I_0 + I_2 = (1.46 - j 10.5) + (16 - j 2.36)$

$$= 17.46 - j 12.86 = 21.7 \angle -36.5^\circ$$

(c) Primary p.f. =  $\cos 36.5^\circ = 0.804$

(d)  $P_g = 3 I_2'^2 R_L' = 3 \times 16.17^2 \times 3.92 = 3,075 \text{ W}$

(e) Synchronous speed  $N_s = 120 \times 60/6 = 1,200 \text{ r.p.m.}$

Actual rotor speed  $N = (1 - s) N_s = (1 - 0.02) \times 1200 = 1,176 \text{ r.p.m.}$

$\therefore T_g = 9.55 \cdot \frac{P_m}{N} = 9.55 \times \frac{3075}{1176} = 24.97 \text{ N - m}$

(f) Primary power input =  $\sqrt{3} V_1 I_1 \cos \phi = \sqrt{3} \times 115 \times 21.7 \times 0.804 = 3,450 \text{ W}$

(g) Gross efficiency =  $3,075 \times 100/3,450 = 89.5 \%$

Fig. 34.57

**Alternative Solution**

Instead of using the equivalent circuit of Fig. 34.57, we could use that shown in Fig. 34.49 which is reproduced in Fig. 34.58.

$$\begin{aligned}
 (a) \quad I_2' &= \frac{V_1}{(R_1 + R_2'/s) + j(X_1 + X_2')} \\
 &= \frac{66.5 \angle 0^\circ}{(0.07 + 0.08/0.02) + j(0.3 + 0.3)} \\
 &= \frac{66.5}{4.07 + j0.6} \\
 &= 16 - j2.36 = 16.17 \angle -8.4^\circ
 \end{aligned}$$

(b)  $I_1 = I_0 + I_2 = 21.7 \angle -36.5^\circ$  ...as before

(c) primary p.f. = **0.804** ...as before

(d) gross power developed,  $P_g = 3 I_2'^2 R_2' \left(\frac{1-s}{s}\right)$

$$= 3 \times 16.17^2 \times 0.08 \left(\frac{1-0.02}{0.02}\right) = \mathbf{3075 \text{ W}}$$

Fig. 34.58

The rest of the solution is the same as above.

**Example 34.60.** The equivalent circuit of a 400 V, 3-phase induction motor with a star-connected winding has the following impedances per phase referred to the stator at standstill:

Stator :  $(0.4 + j 1)$  ohm; Rotor :  $(0.6 + j 1)$  ohm; Magnetising branch :  $(10 + j 50)$  ohm.

Find (i) maximum torque developed (ii) slip at maximum torque and (iii) p.f. at a slip of 5%. Use approximate equivalent circuit. **(Elect. Machinery-III, Bangalore Univ. 1987)**

**Solution.** (i) Gap power transferred and hence the mechanical torque developed by rotor would be maximum when there is maximum transfer of power to the resistor  $R_2'/s$  shown in the approximate equivalent circuit of the motor in Fig. 34.59. It will happen when  $R_2'/s$  equals the impedance looking back into the supply source. Hence,

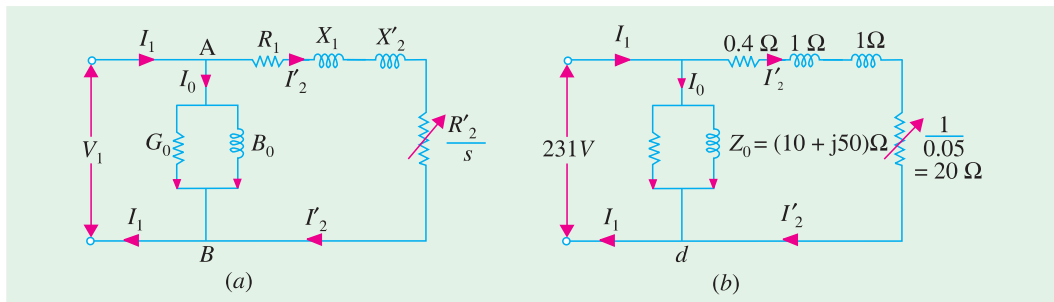

Fig. 34.59

$$\frac{R_2'}{s_m} = \sqrt{R_1^2 + (X_1 + X_2')^2}$$

or

$$s_m = \frac{R_2'}{\sqrt{R_1^2 + (X_1 + X_2')^2}} = \frac{0.6}{\sqrt{0.4^2 + 2^2}} = 0.29 \text{ or } \mathbf{29\%}$$

(i) Maximum value of gross torque developed by rotor

$$T_{g \text{ max}} = \frac{P_{g \text{ max}}}{2\pi N_s/60} = \frac{3 I_2'^2 R_2'/s_m}{2\pi N_s/60} \text{ N - m}$$

Now, 
$$I_2' = \frac{V_1}{\sqrt{(R_1 + R_2')^2 + (X_1 + X_2')^2}} = \frac{400/\sqrt{3}}{\sqrt{(0.4 + 0.6)^2 + (1 + 1)^2}} = 103.3 \text{ A}$$

$$\therefore T_{g-max} = \frac{3 \times 103.3^2 \times 1/0.29}{2\pi \times 1500/60} = 351 \text{ N-m} \quad \dots \text{ assuming } N_s = 1500 \text{ r.p.m.}$$

(iii) The equivalent circuit for one phase for a slip of 0.05 is shown in Fig. 32.59 (b).

$$I_2' = 231 / [(20 + 0.4) + j 2] = 11.2 - j 1.1$$

$$I_0 = 231 / (10 + j 50) = 0.89 - j 4.4$$

$$I_1 = I_0 + I_2' = 12.09 - j 5.5 = 13.28 \angle - 24.4^\circ; \text{ p.f.} = \cos 24.4^\circ = 0.91 \text{ (lag)}$$

**Tutorial Problem No. 34.4.**

- A 3-phase, 115-volt induction motor has the following constants :  $R_2 = 0.07 \Omega$  ;  $R_2' = 0.08 \Omega$  ,  $X_1 = 0.4 \Omega$  and  $X_2' = 0.2 \Omega$ . All the values are for one phase only. At which slip the gross power output will be maximum and the value of the gross power output ? **[11.4% ; 8.6 kW]**
- A 3-phase, 400-V, Y-connected induction motor has an equivalent T-circuit consisting of  $R_1 = 1 \Omega$  ,  $X_1 = 2 \Omega$  , equivalent rotor values are  $R_2' = 1.2 \Omega$  ,  $X_2' = 1.5 \Omega$ . The exciting branch has an impedance of  $(4 + j 40) \Omega$ . If slip is 5% find (i) current (ii) efficiency (iii) power factor (iv) output. Assume friction loss to be 250 W. **[ (i) 10.8 A (ii) 81% (iii) 0.82 (iv) 5 kW]**
- A 50 HP, 440 Volt, 3-phase, 50 Hz Induction motor with star-connected stator winding gave the following test results:  
 (i) No load test: Applied line voltage 440 V, line current 24 A, wattmeter reading 5150 and 3350 watts.  
 (ii) Blocked rotor test: applied line voltage 33.6 volt, line current 65 A, wattmeter reading 2150 and 766 watts.  
 Calculate the parameters of the equivalent circuit.

**OBJECTIVE TESTS – 34**

- Regarding skewing of motor bars in a squirrel-cage induction motor, (SCIM) which statement is false ?  
 (a) it prevents cogging  
 (b) it increases starting torque  
 (c) it produces more uniform torque  
 (d) it reduces motor 'hum' during its operation.
- The principle of operation of a 3-phase. Induction motor is most similar to that of a  
 (a) synchronous motor  
 (b) repulsion-start induction motor  
 (c) transformer with a shorted secondary  
 (d) capacitor-start, induction-run motor.
- The magnetising current drawn by transformers and induction motors is the cause of their .....power factor.  
 (a) zero (b) unity  
 (c) lagging (d) leading.
- The effect of increasing the length of air-gap in an induction motor will be to increase the  
 (a) power factor  
 (b) speed  
 (c) magnetising current  
 (d) air-gap flux.  
**(Power App-II, Delhi Univ. Jan. 1987)**
- In a 3-phase induction motor, the relative speed of stator flux with respect to .....is zero.  
 (a) stator winding (b) rotor  
 (c) rotor flux (d) space.
- An eight-pole wound rotor induction motor operating on 60 Hz supply is driven at 1800 r.p.m. by a prime mover in the opposite direction of revolving magnetic field. The frequency of rotor current is  
 (a) 60 Hz (b) 120 Hz  
 (c) 180 Hz (d) none of the above.

**(Elect. Machines, A.M.I.E. Sec. B, 1993)**

7. A 3-phase, 4-pole, 50-Hz induction motor runs at a speed of 1440 r.p.m. The rotating field produced by the rotor rotates at a speed of .....r.p.m. with respect to the rotor.  
 (a) 1500 (b) 1440  
 (c) 60 (d) 0.
8. In a 3- $\phi$  induction motor, the rotor field rotates at synchronous speed with respect to  
 (a) stator (b) rotor  
 (c) stator flux (d) none of the above.
9. Irrespective of the supply frequency, the torque developed by a SCIM is the same whenever ..... is the same.  
 (a) supply voltage (b) external load  
 (c) rotor resistance (d) slip speed.
10. In the case of a 3- $\phi$  induction motor having  $N_s = 1500$  rpm and running with  $s = 0.04$   
 (a) revolving speed of the stator flux is space is .....rpm  
 (b) rotor speed is .....rpm  
 (c) speed of rotor flux relative to the rotor is .....rpm  
 (d) speed of the rotor flux with respect to the stator is .....rpm.
11. The number of stator poles produced in the rotating magnetic field of a 3- $\phi$  induction motor having 3 slots per pole per phase is  
 (a) 3 (b) 6  
 (c) 2 (d) 12
12. The power factor of a squirrel-cage induction motor is  
 (a) low at light loads only  
 (b) low at heavy loads only  
 (c) low at light and heavy loads both  
 (d) low at rated load only.
- (Elect. Machines, A.M.I.E. Sec. B, 1993)**
13. Which of the following rotor quantity in a SCIM does NOT depend on its slip ?  
 (a) reactance (b) speed  
 (c) induced emf (d) frequency.
14. A 6-pole, 50-Hz, 3- $\phi$  induction motor is running at 950 rpm and has rotor Cu loss of 5 kW. Its rotor input is .....kW.  
 (a) 100 (b) 10  
 (c) 95 (d) 5.3.
15. The efficiency of a 3-phase induction motor is approximately proportional to  
 (a)  $(1-s)$  (b)  $s$   
 (c)  $N$  (d)  $N_s$
16. A 6-pole, 50-Hz, 3- $\phi$  induction motor has a full-load speed of 950 rpm. At half-load, its speed would be .....rpm.  
 (a) 475 (b) 500  
 (c) 975 (d) 1000
17. If rotor input of a SCIM running with a slip of 10% is 100 kW, gross power developed by its rotor is ..... kW.  
 (a) 10 (b) 90  
 (c) 99 (d) 80
18. Pull-out torque of a SCIM occurs at that value of slip where rotor power factor equals  
 (a) unity (b) 0.707  
 (c) 0.866 (d) 0.5
19. Fill in the blanks.  
 When load is placed on a 3-phase induction motor, its  
 (i) speed .....  
 (ii) slip .....  
 (iii) rotor induced emf .....  
 (iv) rotor current .....  
 (v) rotor torque .....  
 (vi) rotor continues to rotate at that value of slip at which developed torque equals ..... torque.
20. When applied rated voltage per phase is reduced by one-half, the starting torque of a SCIM becomes ..... of the starting torque with full voltage.  
 (a)  $1/2$  (b)  $1/4$   
 (c)  $1/\sqrt{2}$  (d)  $\sqrt{3}/2$
21. If maximum torque of an induction motor is 200 kg-m at a slip of 12%, the torque at 6% slip would be ..... kg-m.  
 (a) 100 (b) 160  
 (c) 50 (d) 40
22. The fractional slip of an induction motor is the ratio  
 (a) rotor Cu loss/rotor input  
 (b) stator Cu loss/stator input  
 (c) rotor Cu loss/rotor output  
 (d) rotor Cu loss/stator Cu loss
23. The torque developed by a 3-phase induction motor depends on the following three factors:  
 (a) speed, frequency, number of poles  
 (b) voltage, current and stator impedance  
 (c) synchronous speed, rotor speed and frequency

- (d) rotor emf, rotor current and rotor p.f.
24. If the stator voltage and frequency of an induction motor are reduced proportionately, its
- (a) locked rotor current is reduced
  - (b) torque developed is increased
  - (c) magnetising current is decreased
  - (d) both (a) and (b)
25. The efficiency and p.f. of a SCIM increases in proportion to its
- (a) speed
  - (b) mechanical load
  - (c) voltage
  - (d) rotor torque
26. A SCIM runs at *constant* speed only so long as
- (a) torque developed by it remains constant
  - (b) its supply voltage remains constant
  - (c) its torque exactly equals the mechanical load
  - (d) stator flux remains constant
27. The synchronous speed of a linear induction motor does NOT depend on
- (a) width of pole pitch
  - (b) number of poles
  - (c) supply frequency
  - (d) any of the above
28. Thrust developed by a linear induction motor depends on
- (a) synchronous speed
  - (b) rotor input
  - (c) number of poles
  - (d) both (a) and (b)

## COMPUTATIONS AND CIRCLE DIAGRAMS

This chapter explains you how to derive performance characteristics of induction motors using circular diagrams

35.1. General

In this chapter, it will be shown that the performance characteristics of an induction motor are derivable from a circular locus. The data necessary to draw the circle diagram may be found from no-load and blocked-rotor tests, corresponding to the open-circuit and short-circuit tests of a transformer. The stator and rotor Cu losses can be separated by drawing a torque line. The parameters of the motor, in the equivalent circuit, can be found from the above tests, as shown below.

35.2. Circle Diagram for a Series Circuit

It will be shown that the end of the current vector for a series circuit with constant reactance and voltage, but with a variable resistance is a circle. With reference to Fig. 35.1, it is clear that

$$I = \frac{V}{Z} = \frac{V}{\sqrt{(R^2 + X^2)}}$$

$$= \frac{V}{X} \times \frac{X}{\sqrt{(R^2 + X^2)}} = \frac{V}{X} \sin \phi$$

$$\therefore \sin \phi = \frac{X}{\sqrt{(R^2 + X^2)}} \quad \text{— Fig. 35.2}$$

$\therefore I = (V/X) \sin \phi$

Fig. 35.1

Fig. 35.2

It is the equation of a circle in polar co-ordinates, with diameter equal to  $V/X$ . Such a circle is drawn in Fig. 35.3, using the magnitude of the current and power factor angle  $\phi$  as polar co-ordinates of the point A. In other words, as resistance R is varied (which means, in fact,  $\phi$  is changed), the end of the current vector lies on a circle with diameter equal to  $V/X$ . For a lagging current, it is usual to orientate the circle of Fig. 35.3 (a) such that its diameter is horizontal and the voltage vector takes a vertical position, as shown in Fig. 35.3 (b). There is no difference between the two so far as the magnitude and phase relationships are concerned.

Fig. 35.3

35.3. Circle Diagram for the Approximate Equivalent Circuit

The approximate equivalent diagram is redrawn in Fig. 35.4. It is clear that the circuit to the right of points  $ab$  is similar to a series circuit, having a constant voltage  $V_1$  and reactance  $X_{01}$  but variable resistance (corresponding to different values of slip  $s$ ).

Hence, the end of current vector for  $I_2'$  will lie on a circle with a diameter of  $V/X_{01}$ . In Fig. 35.5,  $I_2'$  is the rotor current referred to stator,  $I_0$  is no-load current (or exciting current) and  $I_1$  is the total stator current and is the vector sum of the first two. When  $I_2'$  is lagging and  $\phi_2 = 90^\circ$ , then the position of vector for  $I_2'$  will be along  $OC$  i.e. at right angles to the voltage vector  $OE$ . For any other value of  $\phi_2$ , point A will move along the circle shown dotted. The exciting current  $I_0$  is drawn lagging  $V$  by an angle  $\phi_0$ . If conductance  $G_0$  and susceptance

Fig. 35.4

$B_0$  of the exciting circuit are assumed constant, then  $I_0$  and  $\phi_0$  are also constant. The end of current vector for  $I_1$  is also seen to lie on another circle which is displaced from the dotted circle by an amount  $I_0$ . Its diameter is still  $V/X_{01}$  and is parallel to the horizontal axis  $OC$ . Hence, we find that if an induction motor is tested at various loads, the locus of the end of the vector for the current (drawn by it) is a circle.

### 35.4. Determination of $G_0$ and $B_0$

If the total leakage reactance  $X_{01}$  of the motor, exciting conductance  $G_0$  and exciting susceptance  $B_0$  are found, then the position of the circle  $O'BC'$  is determined uniquely. One method of finding  $G_0$  and  $B_0$  consists in running the motor synchronously so that slip  $s = 0$ . In practice, it is impossible for an induction motor to run at synchronous speed, due to the inevitable presence of friction and windage losses. However, the induction motor may be run at synchronous speed by

Fig. 35.5

Fig. 35.6

another machine which supplies the friction and windage losses. In that case, the circuit to the right of points  $ab$  behaves like an open circuit, because with  $s = 0$ ,  $R_L = \infty$  (Fig. 35.6). Hence, the current drawn by the motor is  $I_0$  only. Let

$V$  = applied voltage/phase;  $I_0$  = motor current / phase

$W$  = wattmeter reading *i.e.* input in watt ;  $Y_0$  = exciting admittance of the motor. Then, for a 3-phase induction motor

$$W = 3G_0V^2 \quad \text{or} \quad G_0 = \frac{W}{3V^2} \quad \text{Also, } I_0 = V Y_0 \quad \text{or} \quad Y_0 = I_0/V$$

$$B_0 = \sqrt{(Y_0^2 - G_0^2)} = \sqrt{[(I_0/V)^2 - G_0^2]}$$

Hence,  $G_0$  and  $B_0$  can be found.

### 35.5. No-load Test

In practice, it is neither necessary nor feasible to run the induction motor synchronously for getting  $G_0$  and  $B_0$ . Instead, the motor is run without any external mechanical load on it. The speed of the rotor would not be synchronous, but very much near to it ; so that, for all practical purposes, the speed may be assumed synchronous. The no load test is carried out with different values of applied voltage, below and above the value of normal voltage. The power input is measured by two wattmeters,

Fig. 35.7

Fig. 35.8

$I_0$  by an ammeter and  $V$  by a voltmeter, which are included in the circuit of Fig. 35.7. As motor is running on light load, the p.f. would be low *i.e.* less than 0.5, hence total power input will be the difference of the two wattmeter readings  $W_1$  and  $W_2$ . The readings of the total power input  $W_0$ ,  $I_0$  and voltage  $V$  are plotted as in Fig. 35.8. If we extend the curve for  $W_0$ , it cuts the vertical axis at point  $A$ .  $OA$  represents losses due to friction and windage. If we subtract loss corresponding to  $OA$  from  $W_0$ , then we get the no-load electrical and magnetic losses in the machine, because the no-load input  $W_0$  to the motor consists of

- (i) small stator Cu loss  $3 I_0^2 R_1$
- (ii) stator core loss  $W_{CL} = 3G_0 V^2$
- (iii) loss due to friction and windage.

The losses (ii) and (iii) are collectively known as fixed losses, because they are independent of load.  $OB$  represents normal voltage. Hence, losses at normal voltage can be found by drawing a vertical line from  $B$ .

$$BD = \text{loss due to friction and windage} \quad DE = \text{stator Cu loss} \quad EF = \text{core loss}$$

Hence, knowing the core loss  $W_{CL}$ ,  $G_0$  and  $B_0$  can be found, as discussed in Art. 35.4.

$$\text{Additionally, } \phi_0 \text{ can also be found from the relation } W_0 = \sqrt{3} V_L I_0 \cos \phi_0$$

$$\therefore \cos \phi_0 = \frac{W_0}{\sqrt{3} V_L I_0} \quad \text{where } V_L = \text{line voltage and } W_0 \text{ is no-load stator input.}$$

**Example 35.1.** In a no-load test, an induction motor took 10 A and 450 watts with a line voltage of 110 V. If stator resistance/phase is 0.05  $\Omega$  and friction and windage losses amount to 135 watts, calculate the exciting conductance and susceptance/phase.

**Solution.** stator Cu loss =  $3 I_0^2 R_1 = 3 \times 10^2 \times 0.05 = 15 \text{ W}$

$\therefore$  stator core loss =  $450 - 135 - 15 = 300 \text{ W}$

Voltage/phase  $V = 110/\sqrt{3} \text{ V}$ ; Core loss =  $3 G_0 V^2$

$$300 = 3 G_0 \times (110/\sqrt{3})^2 ; G_0 = \frac{300}{3 \times (110/\sqrt{3})^2} = \mathbf{0.025 \text{ siemens/phase}}$$

$Y_0 = I_0 / V = (10 \times \sqrt{3}) / 110 = 0.158 \text{ siemens/phase}$

$$B_0 = \sqrt{Y_0^2 - G_0^2} = \sqrt{(0.158^2 - 0.025^2)} = \mathbf{0.156 \text{ siemens/phase.}}$$

### 35.6. Blocked Rotor Test

It is also known as locked-rotor or short-circuit test. This test is used to find—

1. short-circuit current with *normal* voltage applied to stator
2. power factor on short-circuit

Both the values are used in the construction of circle diagram

3. total leakage reactance  $X_{01}$  of the motor as referred to primary (*i.e.* stator)
4. total resistance of the motor  $R_{01}$  as referred to primary.

In this test, the rotor is locked (or allowed very slow rotation)

This vertical test stand is capable of absorbing up to 10,000 N-m of torque at continuous load rating (max 150.0 hp at 1800 rpm). It helps to develop speed torque curves and performs locked rotor testing

and the rotor windings are short-circuited at slip-rings, if the motor has a wound rotor. Just as in the case of a short-circuit test on a transformer, a reduced voltage (up to 15 or 20 per cent of normal value) is applied to the stator terminals and is so adjusted that full-load current flows in the stator. As in this case  $s = 1$ , the equivalent circuit of the motor is exactly like a transformer, having a short-circuited secondary. The values of current, voltage and power input on short-circuit are measured by the ammeter, voltmeter and wattmeter connected in the circuits as before. Curves connecting the above quantities may also be drawn by taking two or three additional sets of readings at progressively reduced voltages of the stator.

(a) It is found that relation between the short-circuit current and voltage is approximately a straight line. Hence, if  $V$  is normal stator voltage,  $V_s$  the short-circuit voltage (a fraction of  $V$ ), then short-circuit or standstill rotor current, if normal voltage were applied to stator, is found from the relation

$$I_{SN} = I_s \times V/V_s$$

where

$$I_{SN} = \text{short-circuit current obtainable with normal voltage}$$

$$I_s = \text{short-circuit current with voltage } V_s$$

(b) Power factor on short-circuit is found from

$$W_s = \sqrt{3} V_{SL} I_{SL} \cos \phi_s; \quad \therefore \cos \phi_s = W_s / (\sqrt{3} V_{SL} I_{SL})$$

where

$$W_s = \text{total power input on short-circuit}$$

$$V_{SL} = \text{line voltage on short-circuit}$$

$$I_{SL} = \text{line current on short-circuit.}$$

(c) Now, the motor input on short-circuit consists of

(i) mainly stator and rotor Cu losses

(ii) core-loss, which is small due to the fact that applied voltage is only a small percentage of the normal voltage. This core-loss (if found appreciable) can be calculated from the curves of Fig. 35.8.

$$\therefore \begin{aligned} \text{Total Cu loss} &= W_s - W_{CL} \\ 3 I_s^2 R_{01} &= W_s - W_{CL} : \quad R_{01} = (W_s - W_{CL}) / 3 I_s^2 \end{aligned}$$

(d) With reference to the approximate equivalent circuit of an induction motor (Fig. 35.4), motor leakage reactance per phase  $X_{01}$  as referred to the stator may be calculated as follows :

$$Z_{01} = V_s / I_s \quad X_{01} = \sqrt{(Z_{01}^2 - R_{01}^2)}$$

Usually,  $X_1$  is assumed equal to  $X_2'$  where  $X_1$  and  $X_2$  are stator and rotor reactances per phase respectively as referred to stator.  $X_1 = X_2' = X_{01} / 2$

If the motor has a wound rotor, then stator and rotor resistances are separated by dividing  $R_{01}$  in the ratio of the d.c. resistances of stator and rotor windings.

In the case of squirrel-cage rotor,  $R_1$  is determined as usual and after allowing for 'skin effect' is subtracted from  $R_{01}$  to give  $R_2'$  – the effective rotor resistance as referred to stator.

$$\therefore R_2' = R_{01} - R_1$$

**Example 35.2.** A 110-V, 3- $\phi$ , star-connected induction motor takes 25 A at a line voltage of 30 V with rotor locked. With this line voltage, power input to motor is 440 W and core loss is 40 W. The d.c. resistance between a pair of stator terminals is 0.1  $\Omega$ . If the ratio of a.c. to d.c. resistance is 1.6, find the equivalent leakage reactance/phase of the motor and the stator and rotor resistance per phase. (Electrical Technology, Madras Univ. 1987)

**Solution.** S.C. voltage/phase,  $V_s = 30 / \sqrt{3} = 17.3 \text{ V} ; I_s = 25 \text{ A per phase}$   
 $Z_{01} = 17.3/25 = 0.7 \Omega$  (approx.) per phase

Stator and rotor Cu losses = input – core loss = 440 – 40 = 400 W

$$\therefore 3 \times 25^2 \times R_{01} = 400 \quad \therefore R_{01} = 400/3 \times 625 = \mathbf{0.21 \Omega}$$

where  $R_{01}$  is equivalent resistance/phase of motor as referred to stator.

Leakage reactance/phase  $X_{01} = \sqrt{(0.7^2 - 0.21^2)} = 0.668 \Omega$

d.c. resistance/phase of stator =  $0.1/2 = 0.05 \Omega$

a.c. resistance/phase  $R_1 = 0.05 \times 1.6 = 0.08 \Omega$

Hence, effective resistance/phase of rotor as referred to stator

$$R_2' = 0.21 - 0.08 = \mathbf{0.13 \Omega}$$

### 35.7. Construction of the Circle Diagram

Circle diagram of an induction motor can be drawn by using the data obtained from (1) no-load (2) short-circuit test and (3) stator resistance test, as shown below.

#### Step No. 1

From no-load test,  $I_0$  and  $\phi_0$  can be calculated. Hence, as shown in Fig. 35.9, vector for  $I_0$  can be laid off lagging  $\phi_0$  behind the applied voltage  $V$ .

#### Step No. 2

Next, from blocked rotor test or short-circuit test, short-circuit current  $I_{SN}$  corresponding to normal voltage and  $\phi_s$  are found. The vector  $OA$  represents  $I_{SN} = (I_S V/V_S)$  in magnitude and phase. Vector  $O'A$  represents rotor current  $I_2'$  as referred to stator.

Clearly, the two points  $O'$  and  $A$  lie on the required circle. For finding the centre  $C$  of this circle, chord  $O'A$  is bisected at right angles—its bisector giving point  $C$ . The diameter  $O'D$  is drawn perpendicular to the voltage vector.

Windings inside a motor

Fig. 35.9

For example, the vertical component  $O'P$  of no-load current  $OO'$  represents the no-load input, which supplies core loss, friction and windage loss and a negligibly small amount of stator  $I^2R$  loss. Similarly, the vertical component  $AG$  of short-circuit current  $OA$  is proportional to the motor input on short-circuit or if measured to a proper scale, may be said to equal power input.

#### Step No. 3

**Torque line.** This is the line which separates the stator and the rotor copper losses. When the

As a matter of practical contingency, it is recommended that the scale of current vectors should be so chosen that the diameter is more than 25 cm, in order that the performance data of the motor may be read with reasonable accuracy from the circle diagram. With centre  $C$  and radius =  $CO'$ , the circle can be drawn. The line  $O'A$  is known as **out-put line**.

It should be noted that as the voltage vector is drawn vertically, all vertical distances represent the active or power or energy components of the currents.

rotor is locked, then all the power supplied to the motor goes to meet core losses and Cu losses in the stator and rotor windings. The power input is proportional to  $AG$ . Out of this,  $FG (= O'P)$  represents fixed losses *i.e.* stator core loss and friction and windage losses.  $AF$  is proportional to the sum of the stator and rotor Cu losses. The point  $E$  is such that

$$\frac{AE}{EF} = \frac{\text{rotor Cu loss}}{\text{stator Cu loss}}$$

As said earlier, line  $O'E$  is known as torque line.

**How to locate point E ?**

(i) **Squirrel-cage Rotor.** Stator resistance/phase *i.e.*  $R_1$  is found from stator-resistance test. Now, the short-circuit motor input  $W_s$  is approximately equal to motor Cu losses (neglecting iron losses).

$$\text{Stator Cu loss} = 3I_s^2 R_1 \quad \therefore \text{rotor Cu loss} = W_s - 3I_s^2 R_1 \quad \therefore \frac{AE}{EF} = \frac{W_s - 3I_s^2 R_1}{3I_s^2 R_1}$$

(ii) **Wound Rotor.** In this case, rotor and stator resistances per phase  $r_2$  and  $r_1$  can be easily computed. For any values of stator and rotor currents  $I_1$  and  $I_2$  respectively, we can write

$$\frac{AE}{EF} = \frac{I_2^2 r_2}{I_1^2 r_1} = \frac{r_2}{r_1} \left( \frac{I_2}{I_1} \right)^2; \quad \text{Now, } \frac{I_1}{I_2} = K = \text{transformation ratio}$$

$$\frac{AE}{EF} = \frac{r_2}{r_1} \times \frac{1}{K^2} = \frac{r_2 / K^2}{r_1} = \frac{r_2'}{r_1} = \frac{\text{equivalent rotor resistance per phase}}{\text{stator resistance per phase}}$$

Value of  $K$  may be found from short-circuit test itself by using two ammeters, both in stator and rotor circuits.

Let us assume that the motor is running and taking a current  $OL$  (Fig. 35.9). Then, the perpendicular  $JK$  represents fixed losses,  $JN$  is stator Cu loss,  $NL$  is the rotor input,  $NM$  is rotor Cu loss,  $ML$  is rotor output and  $LK$  is the total motor input.

From our knowledge of the relations between the above-given various quantities, we can write :

$$\begin{aligned} \sqrt{3} \cdot V_L \cdot LK &= \text{motor input} & \sqrt{3} \cdot V_L \cdot JK &= \text{fixed losses} \\ \sqrt{3} \cdot V_L \cdot JN &= \text{stator copper loss} & \sqrt{3} \cdot V_L \cdot MN &= \text{rotor copper loss} \\ \sqrt{3} \cdot V_L \cdot MK &= \text{total loss} & \sqrt{3} \cdot V_L \cdot ML &= \text{mechanical output} \\ \sqrt{3} \cdot V_L \cdot NL &= \text{rotor input} \propto \text{torque} \end{aligned}$$

1.  $ML / LK = \text{output/input} = \text{efficiency}$
2.  $MN / NL = (\text{rotor Cu loss}) / (\text{rotor input}) = \text{slip, } s.$
3.  $\frac{ML}{NL} = \frac{\text{rotor output}}{\text{rotor input}} = 1 - s = \frac{N}{N_s} = \frac{\text{actual speed}}{\text{synchronous speed}}$
4.  $\frac{LK}{OL} = \text{power factor}$

Hence, it is seen that, at least, theoretically, it is possible to obtain all the characteristics of an induction motor from its circle diagram. As said earlier, for drawing the circle diagram, we need (a) stator-resistance test for separating stator and rotor Cu losses and (b) the data obtained from (i) no-load test and (ii) short-circuit test.

**35.8. Maximum Quantities**

It will now be shown from the circle diagram (Fig. 35.10) that the maximum values occur at the positions stated below :

(i) **Maximum Output**

It occurs at point M where the tangent is parallel to output line  $O'A$ . Point  $M$  may be located by

drawing a line  $CM$  from point  $C$  such that it is perpendicular to the output line  $O'A$ . Maximum output is represented by the vertical  $MP$ .

**(ii) Maximum Torque or Rotor Input**

It occurs at point  $N$  where the tangent is parallel to torque line  $O'E$ . Again, point  $N$  may be found by drawing  $CN$  perpendicular to the torque line. Its value is represented by  $NQ$ . Maximum torque is also known as stalling or pull-out torque.

**(iii) Maximum Input Power**

It occurs at the highest point of the circle *i.e.* at point  $R$  where the tangent to the circle is horizontal. It is proportional to  $RS$ . As the point  $R$  is beyond the point of maximum torque, the induction motor will be unstable here. However, the maximum input is a measure of the size of the circle and is an indication of the ability of the motor to carry short-time over-loads. Generally,  $RS$  is twice or thrice the motor input at rated load.

Fig. 35.10

**Example 35.3.** A 3-ph, 400-V induction motor gave the following test readings;

No-load : 400 V, 1250 W, 9 A, Short-circuit : 150 V, 4 kW, 38 A

Draw the circle diagram.

If the normal rating is 14.9 kW, find from the circle diagram, the full-load value of current, p.f. and slip.

(Electrical Machines-I, Gujarat Univ. 1985)

**Solution.**

$$\cos \phi_0 = \frac{1250}{\sqrt{3} \times 400 \times 9} = 0.2004 ; \quad \phi_0 = 78.5^\circ$$

Fig. 35.11

$$\cos \phi_S = \frac{4000}{\sqrt{3} \times 150 \times 38} = 0.405 ; \quad \phi_S = 66.1^\circ$$

Short-circuit current with normal voltage is  $I_{SN} = 38 (400/150) = 101.3$  A. Power taken would be  $= 4000 (400/150)^2 = 28,440$  W. In Fig. 33.11,  $OO'$  represents  $I_0$  of 9 A. If current scale is 1 cm = 5 A,

then vector  $OO' = 9/5 = 1.8 \text{ cm}^*$  and is drawn at an angle of  $\phi_0 = 78.5^\circ$  with the vertical  $OV$  (which represents voltage). Similarly,  $OA$  represents  $I_{SN}$  (S.C. current with normal voltage applied) equal to 101.3 A. It measures  $101.3/5 = 20.26^*$  cm and is drawn at an angle of  $66.1^\circ$ , with the vertical  $OV$ .

Line  $O'D$  is drawn parallel to  $OX$ .  $NC$  is the right-angle bisector of  $O'A$ . The semi-circle  $O'AD$  is drawn with  $C$  as the centre. This semi-circle is the locus of the current vector for all load conditions from no-load to short-circuit. Now,  $AF$  represents 28,440 W and measures 8.1 cm. Hence, power scale becomes : 1 cm = 28,440/8.1 = 3,510 W. Now, full-load motor output =  $14.9 \times 10^3 = 14,900 \text{ W}$ . According to the above calculated power scale, the intercept between the semi-circle and output line  $O'A$  should measure =  $14,900/3510 = 4.25 \text{ cm}$ . For locating full-load point  $P$ ,  $BA$  is extended.  $AS$  is made equal to 4.25 cm and  $SP$  is drawn parallel to output line  $O'A$ .  $PL$  is perpendicular to  $OX$ .

Line current =  $OP = 6 \text{ cm} = 6 \times 5 = 30 \text{ A}$ ;  $\phi = 30^\circ$  (by measurement)

p.f. =  $\cos 30^\circ = 0.886$  (or  $\cos \phi = PL/OP = 5.2/6 = 0.865$ )

Now, slip =  $\frac{\text{rotor Cu loss}}{\text{rotor input}}$

In Fig. 35.11,  $EK$  represents rotor Cu loss and  $PK$  represents rotor input.

$\therefore$  slip =  $\frac{EK}{PK} = \frac{0.3}{4.5} = 0.067$  or **6.7%**

**Example 35.4.** Draw the circle diagram for a 3.73 kW, 200-V, 50-Hz, 4-pole, 3- $\phi$  star-connected induction motor from the following test data :

No-load : Line voltage 200 V, line current 5 A; total input 350 W

Blocked rotor : Line voltage 100 V, line current 26 A; total input 1700 W

Estimate from the diagram for full-load condition, the line current, power factor and also the maximum torque in terms of the full-load torque. The rotor Cu loss at standstill is half the total Cu loss. **(Electrical Engineering, Bombay Univ. 1987)**

Fig. 35.12

**Solution. No-load test**

$$I_0 = 5 \text{ A, } \cos \phi_0 = \frac{350}{\sqrt{3} \times 200 \times 5} = 0.202 ; \phi_0 = 78^\circ 15'$$

\* The actual lengths are different from these values, due to reduction in block making.

**Blocked-rotor test :**

$$\cos \phi_s = \frac{1700}{\sqrt{3} \times 100 \times 26} = 0.378 ; \phi_s = 67^\circ 42'$$

Short-circuit current with normal voltage,  $I_{SN} = 26 \times 200/100 = 52 \text{ A}$

Short-circuit/blocked rotor input with normal voltage =  $1700(52/26)^2 = 6,800 \text{ W}$

In the circle diagram of Fig. 35.12, voltage is represented along  $OV$  which is drawn perpendicular to  $OX$ . Current scale is  $1 \text{ cm} = 2 \text{ A}$

Line  $OA$  is drawn at an angle of  $\phi_0 = 78^\circ 15'$  with  $OV$  and  $2.5 \text{ cm}$  in length. Line  $A X'$  is drawn parallel to  $OX$ . Line  $OB$  represents short-circuit current with normal voltage *i.e.*  $52 \text{ A}$  and measures  $52/2 = 26 \text{ cm}$ .  $AB$  represents output line. Perpendicular bisector of  $AB$  is drawn to locate the centre  $C$  of the circle. With  $C$  as centre and radius =  $CA$ , a circle is drawn which passes through points  $A$  and  $B$ . From point  $B$ , a perpendicular is drawn to the base.  $BD$  represents total input of  $6,800 \text{ W}$  for blocked rotor test. Out of this,  $ED$  represents no-load loss of  $350 \text{ W}$  and  $BE$  represents  $6,800 - 350 = 6,450 \text{ W}$ . Now  $BD = 9.8 \text{ cm}$  and represents  $6,800 \text{ W}$

$$\therefore \text{power scale} = 6,800/9.8 = 700 \text{ watt/cm} \quad \text{or} \quad 1 \text{ cm} = 700 \text{ W}$$

$BE$  which represents total copper loss in rotor and stator, is bisected at point  $T$  to separate the two losses.  $AT$  represents torque line.

Now, motor output =  $3,730 \text{ watt}$ . It will be represented by a line =  $3,730/700 = 5.33 \text{ cm}$

The output point  $P$  on the circle is located thus :

$DB$  is extended and  $BR$  is cut =  $5.33 \text{ cm}$ . Line  $RP$  is drawn parallel to output line  $AB$  and cuts the circle at point  $P$ . Perpendicular  $PS$  is drawn and  $P$  is joined to origin  $O$ .

Point  $M$  corresponding to maximum torque is obtained thus :

From centre  $C$ , a line  $CM$  is drawn such that it is perpendicular to torque line  $AT$ . It cuts the circle at  $M$  which is the required point. Point  $M$  could also have been located by drawing a line parallel to the torque line.  $MK$  is drawn vertical and it represents maximum torque.

Now, in the circle diagram,  $OP =$  line current on full-load =  $7.6 \text{ cm}$ . Hence,  $OP$  represents  $7.6 \times 2 = 15.2 \text{ A}$

$$\text{Power factor on full-load} = \frac{SP}{OP} = \frac{6.45}{7.6} = 0.86$$

$$\frac{\text{Max. torque}}{\text{F.L. torque}} = \frac{MK}{PG} = \frac{10}{5.6} = 1.8$$

$$\therefore \text{Max. torque} = 180\% \text{ of full-load torque.}$$

**Example. 35.5.** Draw the circle diagram from no-load and short-circuit test of a 3-phase.  $14.92 \text{ kW}$ ,  $400\text{-V}$ ,  $6\text{-pole}$  induction motor from the following test results (line values).

No-load :  $400\text{-V}$ ,  $11 \text{ A}$ ,  $p.f. = 0.2$

Short-circuit :  $100\text{-V}$ ,  $25 \text{ A}$ ,  $p.f. = 0.4$

Rotor  $\text{Cu}$  loss at standstill is half the total  $\text{Cu}$  loss.

From the diagram, find (a) line current, slip, efficiency and *p.f.* at full-load (b) the maximum torque. **(Electrical Machines-I, Gujarat Univ. 1985)**

**Solution.** No-load *p.f.* =  $0.2$ ;  $\phi_0 = \cos^{-1}(0.2) = 78.5^\circ$

Short-circuit *p.f.* =  $0.4$ ;  $\phi_s = \cos^{-1}(0.4) = 66.4^\circ$

S.C. current  $I_{SN}$  if normal voltage were applied =  $25 (400/100) = 100 \text{ A}$

S.C. power input with this current =  $\sqrt{3} \times 400 \times 100 \times 0.4 = 27,710 \text{ W}$

Assume a current scale of 1 cm = 5 A.\* The circle diagram of Fig. 35.13 is constructed as follows :

- (i) No-load current vector  $OO'$  represents 11 A. Hence, it measures  $11/5 = 2.2$  cm and is drawn at an angle of  $78.5^\circ$  with  $OY$ .
- (ii) Vector  $OA$  represents 100 A and measures  $100/5 = 20$  cm. It is drawn at an angle of  $66.4^\circ$  with  $OY$ .
- (iii)  $O'D$  is drawn parallel to  $OX$ .  $NC$  is the right angle bisector of  $O'A$ .
- (iv) With  $C$  as the centre and  $CO'$  as radius, a semicircle is drawn as shown.
- (v)  $AF$  represents power input on short-circuit with normal voltage applied. It measures 8 cm and (as calculated above) represents 27,710 W. Hence, power scale becomes

$$1 \text{ cm} = 27,710/8 = 3,465 \text{ W}$$

Fig. 35.13

(a) F.L motor output = 14,920 W. According to the above power scale, the intercept between the semicircle and the output line  $O'A$  should measure  $= 14,920/3,465 = 4.31$  cm. Hence, vertical line  $PL$  is found which measures 4.31 cm. Point  $P$  represents the full-load operating point.\*\*

(a) Line current =  $OP = 6.5$  cm which means that full-load line current  $= 6.5 \times 5 = 32.5 \text{ A}$ .  $\phi = 32.9^\circ$  (by measurement)

$\therefore \cos 32.9^\circ = 0.84$  (or  $\cos \phi = PL/OP = 5.4/6.5 = 0.84$ )

$$\text{slip} = \frac{EK}{PK} = \frac{0.3}{5.35} = 0.056 \text{ or } 5.6\% ; \eta = \frac{PE}{PL} = \frac{4.3}{5.4} = 0.8 \text{ or } 80\%$$

(b) For finding maximum torque, line  $CM$  is drawn  $\perp$  to torque line  $O'H$ .  $MT$  is the vertical intercept between the semicircle and the torque line and represents the maximum torque of the motor in synchronous watts

Now,  $MT = 7.8$  cm (by measurement)  $\therefore T_{max} = 7.8 \times 3465 = 27,030$  synch. watt

**Example 35.6.** A 415-V, 29.84 kW, 50-Hz, delta-connected motor gave the following test data :

No-load test	: 415 V,	21 A,	1,250 W
Locked rotor test	: 100 V,	45 A,	2,730 W

Construct the circle diagram and determine

\* The actual scale of the book diagram is different because it has been reduced during block making.

\*\* The operating point may also be found by making  $AS = 4.31$  cm and drawing  $SP$  parallel to  $O'A$ .

(a) the line current and power factor for rated output (b) the maximum torque.  
 Assume stator and rotor Cu losses equal at standstill. (A.C. Machines-I, Jadavpur Univ. 1990)

**Solution.** Power factor on no-load is  $= \frac{1250}{\sqrt{3} \times 415 \times 21} = 0.0918$

$\therefore \phi_0 = \cos^{-1}(0.0918) = 84^\circ 44'$

Power factor with locked rotor is  $= \frac{2,730}{\sqrt{3} \times 100 \times 45} = 0.3503$

$\therefore \phi_s = \cos^{-1}(0.3503) = 69^\circ 30'$

The input current  $I_{SN}$  on short-circuit if normal voltage were applied  $= 45 (415/100) = 186.75$  A and power taken would be  $= 2,730 (415/100)^2 = 47,000$  W.

Let the current scale be 1 cm = 10 A. The circle diagram of Fig. 35.14 is constructed as follows :

Fig. 35.14

- (i) Vector  $OO'$  represents 21 A so that it measures 2.1 cm and is laid at an angle of  $84^\circ 44'$  with  $OE$  (which is vertical i.e. along  $Y$ -axis).
- (ii) Vector  $OA$  measures  $186.75/10 = 18.675$  cm and is drawn at an angle of  $69^\circ 30'$  with  $OE$ .
- (iii)  $O'D$  is drawn parallel to  $OX$ .  $NC$  is the right-angle bisector of  $O'A$
- (iv) With  $C$  as the centre and  $CO'$  as radius, a semi-circle is drawn as shown. This semi-circle is the locus of the current vector for all load conditions from no-load to short-circuit.
- (v) The vertical  $AF$  represents power input on short-circuit with normal voltage applied.  $AF$  measures 6.6 cm and (as calculated above) represents 47,000 W. Hence, power scale becomes, 1 cm =  $47,000/6.6 = 7,120$  W
- (a) Full-load output = 29,840 W. According to the above power scale, the intercept between the semicircle and output line  $O'A$  should measure  $29,840/7,120 = 4.19$  cm. Hence, line  $PL$  is found which measures 4.19 cm. Point  $P$  represents the full-load operating point.\*

Phase current  $= OP = 6$  cm =  $6 \times 10 = 60$  A; Line current  $= \sqrt{3} \times 60 = 104$  A

Power factor  $= \cos \angle POE = \cos 35^\circ = 0.819$

- (b) For finding the maximum torque, line  $CM$  is drawn  $\perp$  to the torque line  $O'H$ . Point  $H$  is such that

$$\frac{AH}{BH} = \frac{\text{rotor Cu loss}}{\text{stator Cu loss}}$$

\* The operating point may also be found by making  $AS = 4.19$  cm and drawing  $SP$  parallel to  $O'A$ .

Since the two Cu losses are equal, point  $H$  is the mid-point of  $AB$ .

Line  $MK$  represents the maximum torque of the motor in synchronous watts

$$MK = 7.3 \text{ cm (by measurement)} = 7.3 \times 7,120 = \mathbf{51,980 \text{ synch. watt.}}$$

**Example 35.7.** Draw the circle diagram for a 5.6 kW, 400-V, 3- $\phi$ , 4-pole, 50-Hz, slip-ring induction motor from the following data :

No-load readings : 400 V, 6 A,  $\cos \phi_0 = 0.087$  : Short-circuit test : 100 V, 12 A, 720 W.

The ratio of primary to secondary turns = 2.62, stator resistance per phase is  $0.67 \Omega$  and of the rotor is  $0.185 \Omega$ . Calculate

- (i) full-load current
- (ii) full-load slip
- (iii) full-load power factor
- (iv)  $\frac{\text{maximum torque}}{\text{full - load torque}}$
- (v) maximum power.

**Solution. No-load condition**

$$\phi_0 = \cos^{-1}(0.087) = 85^\circ$$

Fig. 35.15

**Short-circuit condition**

Short-circuit current with normal voltage =  $12 \times 400/100 = 48 \text{ A}$

$$\text{Total input} = 720 \times (48/12)^2 = 11.52 \text{ kW}$$

$$\cos \phi_s = \frac{720}{\sqrt{3} \times 100 \times 12} = 0.347 \quad \text{or} \quad \phi_s = 69^\circ 40'$$

Current scale is,  $1 \text{ cm} = 2 \text{ A}$

In the circle diagram of Fig. 35.15,  $OA = 3 \text{ cm}$  and inclined at  $85^\circ$  with  $OV$ . Line  $OB$  represents short-circuit current with normal voltage. It measures  $48/2 = 24 \text{ cm}$  and represent 48 A.  $BD$  is perpendicular to  $OX$ .

**For Drawing Torque Line**

$$K = 2.62 \qquad R_1 = 0.67 \Omega \qquad R_2 = 0.185 \Omega$$

(in practice, an allowance of 10% is made for skin effect)

$$\therefore \frac{\text{rotor Cu loss}}{\text{stator Cu loss}} = 2.62^2 \times \frac{0.185}{0.67} = 1.9 \qquad \therefore \frac{\text{rotor Cu loss}}{\text{total Cu loss}} = \frac{1.9}{2.9} = 0.655$$

Now  $BD = 8.25 \text{ cm}$  and represents 11.52 kW  
 power scale =  $11.52/8.25 = 1.4 \text{ kW/cm}$

∴  $1 \text{ cm} = 1.4 \text{ kW}$   
 BE represents total Cu loss and is divided at point T in the ratio 1.9 : 1.  
 $BT = BE \times 1.9/2.9 = 0.655 \times 8 = 5.24 \text{ cm}$

AT is the torque line  
 Full-load output = 5.6 kW  
 It is represented by a line =  $5.6/1.4 = 4 \text{ cm}$

DB is produced to R such that BR = 4 cm. Line RP is parallel to output line and cuts the circle at P. OP represents full-load current.

PS is drawn vertically. Points M and Y represent points of maximum torque and maximum output respectively.

(i) F.L. current =  $OP = 5.75 \text{ cm} = 5.75 \times 2 = \mathbf{11.5 \text{ A}}$

(ii) F.L. slip =  $\frac{FG}{PG} = \frac{0.2}{4.25} = 0.047$  or **4.7%**

(iii) p.f. =  $\frac{SP}{OP} = \frac{4.6}{5.75} = \mathbf{0.8}$

(iv)  $\frac{\text{max. torque}}{\text{full-load torque}} = \frac{MK}{PG} = \frac{10.05}{4.25} = \mathbf{2.37}$

(v) Maximum output is represented by  $YL = 7.75 \text{ cm}$ .

∴ Max. output =  $7.75 \times 1.4 = \mathbf{10.8 \text{ kW}}$

**Example 35.8.** A 440-V, 3- $\phi$ , 4-pole, 50-Hz slip-ring motor gave the following test results :

No-load reading : 440 V, 9 A, p.f. = 0.2

Blocked rotor test : 110 V, 22 A, p.f. = 0.3

The ratio of stator to rotor turns per phase is 3.5/1. The stator and rotor Cu losses are divided equally in the blocked rotor test. The full-load current is 20 A. Draw the circle diagram and obtain the following :

- (a) power factor, output power, efficiency and slip at full-load
- (b) standstill torque or starting torque.
- (c) resistance to be inserted in the rotor circuit for giving a starting torque 200 % of the full-load torque. Also, find the current and power factor under these conditions.

**Solution.** No-load p.f. = 0.2 ∴  $\phi_0 = \cos^{-1}(0.2) = 78.5^\circ$

Short-circuit p.f. = 0.3 ∴  $\phi_s = 72.5^\circ$

Short-circuit current at normal voltage =  $22 \times 440/110 = 88 \text{ A}$

S.C. input =  $\sqrt{3} \times 440 \times 88 \times 0.3 = 20,120 \text{ W} = 20.12 \text{ kW}$

Take a current scale of  $1 \text{ cm} = 4 \text{ A}$

In the circle diagram of Fig. 35.16, OA = 2.25 cm drawn at an angle of  $78.5^\circ$  behind OV. Similarly, OB =  $88/4 = 22 \text{ cm}$  and is drawn at an angle of  $72.5^\circ$  behind OV. The semi-circle is drawn as usual. Point T is such that BT = TD. Hence, torque line AT can be drawn. BC represents 20.12 kW. By measurement BC = 6.6 cm.

Fig. 35.16

∴ power scale = 20.12/6.6 = 3.05  
 ∴ 1 cm = 3.05 kW

Full-load current = 20 A. Hence, it is represented by a length of 20/4 = 5 cm. With *O* as centre and 5 cm as radius, an arc is drawn which cuts the semi-circle at point *P*. This point represents full-load condition. *PH* is drawn perpendicular to the base *OC*.

(a) (i) p.f. = cos φ = *PH/OP* = 4.05/5 = **0.81**

(ii) Torque can be found by measuring the input.

Rotor input = *PE* = 3.5 cm = 3.5 × 3.05 = 10.67 kW

Now  $N_s = 120 \times 50/4 = 1500$  r.p.m.

∴  $T_g = 9.55 P_2/N_s = 9.55 \times 10,670/1500 = \mathbf{61 \text{ N-m}}$

(iii) output = *PL* = 3.35 × 3.05 = **10.21 kW**

(iv) efficiency =  $\frac{\text{output}}{\text{input}} = \frac{PL}{PH} = \frac{3.35}{4.05} = 0.83$  or **83%**

(v) slip *s* =  $\frac{\text{rotor Cu loss}}{\text{rotor input}} = \frac{LE}{PE} = \frac{0.1025}{3.5} = 0.03$  or **3%**

(b) Standstill torque is represented by *BT*.

$BT = 3.1 \text{ cm} = 3.1 \times 3.05 = 9.45 \text{ kW}$  ∴  $T_{st} = 9.55 \times \frac{9.45 \times 10^3}{1500} = \mathbf{60.25 \text{ N-m}}$

(c) We will now locate point *M* on the semi-circle which corresponds to a starting torque twice the full-load torque *i.e.* 200% of F.L. torque.

Full-load torque = *PE*. Produce *EP* to point *S* such that *PS* = *PE*. From point *S* draw a line parallel to torque line *AT* cutting the semi-circle at *M*. Draw *MN* perpendicular to the base.

At starting when rotor is stationary, *MN* represents total rotor copper losses.

*NR* = Cu loss in rotor itself as before ; *RM* = Cu loss in external resistance

*RM* = 4.5 cm = 4.5 × 3.05 = 13.716 kW = 13,716 watt.

Cu loss/phase = 13,716/3 = 4,572 watt

Rotor current *AM* = 17.5 cm = 17.5 × 4 = 70 A

Let  $r_2'$  be the additional external resistance in the rotor circuit (as referred to stator) then

$r_2' \times 70^2 = 4,572$  or  $r_2' = 4,572/4,900 = 0.93 \Omega$

Now  $K = 1/3.5$

∴ rotor resistance/phase,  $r_2 = r_2' \times K^2 = 0.93/3.5^2 = \mathbf{0.076 \Omega}$

Stator current = *OM* = 19.6 × 4 = **78.4 A** ; power factor =  $\frac{MF}{OM} = \frac{9.75}{18.7} = \mathbf{0.498}$

**Example 35.9.** Draw the circle diagram of a 7.46 kW, 200-V, 50-Hz, 3-phase slip-ring induction motor with a star-connected stator and rotor, a winding ratio of unity, a stator resistance of 0.38 ohm/phase and a rotor resistance of 0.24 ohm/phase. The following are the test readings ;

No-load : 200 V, 7.7 A,  $\cos \phi_0 = 0.195$

Short-circuit : 100 V, 47.6 A,  $\cos \phi_s = 0.454$

Find (a) starting torque and (b) maximum torque, both in synchronous watts

(c) the maximum power factor (d) the slip for maximum torque

(e) the maximum output (Elect. Tech.-II, Madras Univ. 1989)

**Solution.**  $\phi_0 = \cos^{-1}(0.195) = 78^\circ 45'$ ;  $\phi_s = \cos^{-1}(0.454) = 63^\circ$

The short-circuit  $I_{SN}$  with normal voltage applied is = 47.6 × (200/100) = 95.2 A

The circle diagram is drawn as usual and is shown in fig. 35.17.

With a current scale of 1 cm = 5 A, vector *OO'* measures 7.7/5 = 1.54 cm and represents the no-load current of 7.7 A.

Similarly, vector  $OA$  represents  $I_{SN}$  i.e. short-circuit current with normal voltage and measures  $95.2/5 = 19.04$  cm

Both vectors are drawn at their respective angles with  $OE$ .

The vertical line  $AF$  measures the power input on short-circuit with normal voltage and is  $= \sqrt{3} \times 200 \times 95.2 \times 0.454 = 14,970$  W.

Since  $AF$  measures 8.6 cm, the power scale is  $1 \text{ cm} = 14,970/8.6 = 1740$  W

The point  $H$  is such that

Fig. 35.17

$$\frac{AH}{AB} = \frac{\text{rotor Cu loss}}{\text{total Cu loss}} = \frac{\text{rotor resistance}^*}{\text{rotor + stator resistance}} = \frac{0.24}{0.62}$$

Now  $AB = 8.2$  cm (by measurement)  $\therefore AH = 8.2 \times 0.24/0.62 = 3.2$  cm

(a) Starting torque =  $AH = 3.2$  cm =  $3.2 \times 1740 = 5,570$  synchron. watt.

(b) Line  $CM$  is drawn perpendicular to the torque line  $O'H$ . The intercept  $MN$  represents the maximum torque in synchronous watts.

Maximum torque =  $MN = 7.15$  cm =  $7.15 \times 1740 = 12,440$  synchron. watts.

(c) For finding the maximum power, line  $OP$  is drawn tangential to the semi-circle.

$$\angle POE = 28.5^\circ$$

$$\therefore \text{maximum p.f.} = \cos 28.5^\circ = 0.879$$

(d) The slip for maximum torque is =  $KN/MN = 1.4/7.15 = 0.195$

(e) Line  $CL$  is drawn perpendicular to the output line  $O'A$ . From  $L$  is drawn the vertical line  $LD$ . It measures 5.9 cm and represents the maximum output.

$$\therefore \text{maximum output} = 5.9 \times 1740 = 10,270 \text{ W}$$

### Tutorial Problems 35.1

1. A 300 h.p. (223.8 kW), 3000-V, 3- $\phi$ , induction motor has a magnetising current of 20 A at 0.10 p.f. and a short-circuit (or locked) current of 240 A at 0.25 p.f. Draw the circuit diagram, determine the p.f. at full-load and the maximum horse-power. [**0.85 p.f. 621 h.p. (463.27 kW)**] (I.E.E. London)
2. The following are test results for a 18.65 kW, 3- $\phi$ , 440.V slip-ring induction motor :  
Light load : 440-V, 7.5 A, 1350 W (including 650 W friction loss).

\* Because  $K = 1$ , otherwise it should be  $R_2' = R_2/K^2$ .

S.C. test : 100 V, 32 A, 1800 W

Draw the locus diagram of the stator current and hence obtain the current, p.f. and slip on full-load. On short-circuit, the rotor and stator copper losses are equal. **[30 A, 0.915, 0.035] (London Univ)**

3. Draw the circle diagram for 20 h.p. (14.92 kW), 440-V, 50-Hz, 3- $\phi$  induction motor from the following test figures (line values) :

No-load : 440 V, 10A, p.f. 0.2 Short-circuit : 200 V, 50 A, p.f. 0.4

From the diagram, estimate (a) the line current and p.f. at full-load (b) the maximum power developed (c) the starting torque. Assume the rotor and stator  $I^2R$  losses on short-circuit to be equal.

**[(a) 28.1 A at 0.844 p.f. (b) 27.75 kW (c) 11.6 synchronous kW/phase] (London Univ.)**

4. A 40 h.p. (29.84 kW), 440-V, 50-Hz, 3-phase induction motor gave the following test results

No. load : 440 V, 16 A, p.f. = 0.15 S.C. test : 100 V, 55 A, p.f. = 0.225

Ratio of rotor to stator losses on short-circuit = 0.9. Find the full-load current and p.f., the pull-out torque and the maximum output power developed.

**[49 A at 0.88 p.f. ; 78.5 synch. kW or 2.575 times F.L. torque ; 701.2 kW] (I.E.E. London)**

5. A 40 h.p. (29.84 kW), 50-Hz, 6-pole, 420-V, 3- $\phi$ , slip-ring induction motor furnished the following test figures :

No-load : 420 V, 18 A, p.f. = 0.15 S.C. test : 210 V, 140 A, p.f. = 0.25

The ratio of stator to rotor Cu losses on short-circuit was 7 : 6. Draw the circle diagram and find from it (a) the full-load current and power factor (b) the maximum torque and power developed.

**[(a) 70 A at 0.885 p.f. (b) 89.7 kg.m ; 76.09 kW] (I.E.E. London)**

6. A 500 h.p. (373 kW), 8-pole, 3- $\phi$ , 6,000-V, 50-Hz induction motor gives on test the following figures :

Running light at 6000 V, 14 A/phase, 20,000 W ; Short-circuit at 2000 V, 70 A/phase, 30,500 W

The resistance/phase of the star-connected stator winding is  $1.1 \Omega$ , ratio of transformation is 4 : 1. Draw the circle diagram of this motor and calculate how much resistance must be connected in each phase of the rotor to make it yield full-load torque at starting. **[0.138  $\Omega$ ] (London Univ.)**

7. A 3-phase induction motor has full-load output of 18.65 kW at 220 V, 720 r.p.m. The full-load p.f. is 0.83 and efficiency is 85%. When running light, the motor takes 5 A at 0.2 p.f. Draw the circle diagram and use it to determine the maximum torque which the motor can exert (a) in N-m (b) in terms of full-load torque and (c) in terms of the starting torque.

**[(a) 268.7 N-m (b) 1.08 (c) 7.2 approx.] (London Univ.)**

8. A 415-V, 40 h.p. (29.84 kW), 50.Hz,  $\Delta$ -connected motor gave the following test data :

No-load test : 415 V, 21 A, 1250 W ; Locked rotor test : 100 V, 45 A, 2,730 W

Construct the circle diagram and determine

(a) the line current and power factor for rated output (b) the maximum torque. Assume stator and rotor Cu losses equal at standstill.

**[(a) 104 A : 0.819 (b) 51,980 synch watt] (A.C. Machines-I, Jadavpur Univ. 1978)**

9. Draw the no-load and short circuit diagram for a 14.92 kW., 400-V, 50-Hz, 3-phase star-connected induction motor from the following data (line values) :

No load test : 400 V, 9 A,  $\cos \phi = 0.2$

Short circuit test : 200 V, 50 A,  $\cos \phi = 0.4$

From the diagram find (a) the line current and power factor at full load, and (b) the maximum output power. **[(a) 32.0 A, 0.85 (b) 21.634 kW]**

### 35.9. Starting of Induction Motors

It has been shown earlier that a plain induction motor is similar in action to a polyphase transformer with a short-circuited rotating secondary. Therefore, if normal supply voltage is applied to the stationary motor, then, as in the case of a transformer, a very large initial current is taken by the primary, at least, for a short while. It would be remembered that exactly similar conditions exist in the case of a d.c. motor, if it is thrown directly across the supply lines, because at the time of starting it, there is no back e.m.f. to oppose the initial inrush of current.

Induction motors, when direct-switched, take five to seven times their full-load current and develop only 1.5 to 2.5 times their full-load torque. This initial excessive current is objectionable because it will produce large line-voltage drop that, in turn, will affect the operation of other electrical equipment connected to the same lines. Hence, it is not advisable to line-start motors of rating above 25 kW to 40 kW.

It was seen in Art. 34.15 that the starting torque of an induction motor can be improved by increasing the resistance of the rotor circuit. This is easily feasible in the case of slip-ring motors but not in the case of squirrel-cage motors. However, in their case, the initial in-rush of current is controlled by applying a reduced voltage to the stator during the starting period, full normal voltage being applied when the motor has run up to speed.

### 35.10. Direct-switching or Line starting of Induction Motors

It has been shown earlier that

$$\text{Rotor input} = 2 \pi N_s T = k T \quad \text{---Art. 34.36}$$

Also, rotor Cu loss =  $s \times$  rotor input

$$\therefore 3 I_2^2 R_2 = s \times k T \quad \therefore T \propto I_2^2 / s \quad (\text{if } R_2 \text{ is the same})$$

$$\text{Now } I_2 \propto I_1 \quad \therefore T \propto I_1^2 / s \quad \text{or } T = K I_1^2 / s$$

$$\text{At starting moment } s = 1 \quad \therefore T_{st} = K I_{st}^2 \quad \text{where } I_{st} = \text{starting current}$$

$$\text{If } I_f = \text{normal full-load current and } s_f = \text{full-load slip}$$

$$\text{then } T_f = K I_f^2 / s_f \quad \therefore \frac{T_{st}}{T_f} = \left( \frac{I_{st}}{I_f} \right)^2 \cdot s_f$$

When motor is direct-switched onto normal voltage, then starting current is the short-circuit current  $I_{sc}$ .

$$\therefore \frac{T_{st}}{T_f} = \left( \frac{I_{sc}}{I_f} \right)^2 \cdot s_f = a^2 \cdot s_f \quad \text{where } a = I_{sc} / I_f$$

$$\text{Suppose in a case, } I_{sc} = 7 I_f, s_f = 4\% = 0.04, \text{ the } T_{st} / T_f = 7^2 \times 0.04 = 1.96$$

$$\therefore \text{starting torque} = 1.96 \times \text{full-load torque}$$

Hence, we find that with a current as great as seven times the full-load current, the motor develops a starting torque which is only 1.96 times the full-load value.

Some of the methods for starting induction motors are discussed below :

#### Squirrel-cage Motors

- (a) Primary resistors (or rheostat) or reactors
- (b) Auto-transformer (or autostarter)
- (c) Star-delta switches

In all these methods, terminal voltage of the squirrel-cage motor is reduced during starting.

#### Slip-ring Motors

- (a) Rotor rheostat

### 35.11. Squirrel-cage Motors

#### (a) Primary resistors

Their purpose is to drop some voltage and hence reduce the voltage applied across the motor terminals. In this way, the initial current drawn by the motor is reduced. However, it should be noted that whereas current varies directly as the voltage, the torque varies as square of applied voltage\*

\* When applied voltage is reduced, the rotating flux  $\Phi$  is reduced which, in turn, decreases rotor e.m.f. and hence rotor current  $I_2$ . Starting torque, which depends both on  $\Phi$  and  $I_2$  suffers on two counts when impressed voltage is reduced.

**Squirrel Cage Rotor**

When the stator's moving magnetic field cuts across the rotor's conductor bars, it induces voltage in them. This voltage produces current, which circulates through the bars and around the rotor end ring. This current in turn produces magnetic fields around each rotor bar. The continuously changing stator magnetic field results in a continuously changing rotor field. The rotor becomes an electromagnet with continuously alternating poles, which interact with the stator's poles.

(Art 34.17). If the voltage applied across the motor terminals is reduced by 50%, starting current is reduced by 50%, but torque is reduced to 25% of the full-voltage value.

By using primary resistors (Fig. 35.18), the applied voltage/phase can be reduced by a fraction 'x' (and it additionally improves the power factor of the line slightly).

$$I_{st} = x I_{sc} \quad \text{and} \quad T_{st} = x^2 T_{sc}$$

As seen from Art 35.10, above,

$$\begin{aligned} \frac{T_{st}}{T_f} &= \left( \frac{I_{st}}{I_f} \right)^2 \cdot s_f = \left( \frac{x I_{sc}}{I_f} \right)^2 s_f \\ &= x^2 \left( \frac{I_{sc}}{I_f} \right)^2 s_f = x^2 \cdot a^2 \cdot s_f \end{aligned}$$

It is obvious that the ratio of the starting torque to full-load torque is  $x^2$  of that obtained with direct switching or across-the-line starting. This method is useful for the smooth starting of small machines only.

**(b) Auto-transformers**

Such starters, known variously as *auto-starters* or *compensators*, consist of an auto-transformer, with necessary switches. We may use either two auto-transformers connected as usual [Fig. 35.19 (b)] or 3 auto-transformers connected in open delta [Fig. 35.19 (a)]. **This method can be used both for star-and delta-connected motors.** As shown in Fig. 35.20

with starting connections, a reduced voltage is applied across the motor terminals. When the motor has run up to say, 80% of its normal speed, connections are so changed that auto-transformers are cut out and full supply voltage is applied across the motor. The switch making these changes from 'start' to 'run' may be airbreak (for small motors) or may be oil-immersed (for large motors) to reduce sparking. There is also provision for no-voltage and over-load protection, along with a time-delay device, so that momentary interruption of voltage or momentary over-load do not disconnect the motor from supply line. Most of the auto-starters are provided with 3 sets of taps, so as to reduce voltage to 80, 65 or 50 per cent of the line voltage, to suit the local conditions of supply. The

Fig. 35.18

V-connected auto-transformer is commonly used, because it is cheaper, although the currents are unbalanced during starting period. This is, however, not much objectionable firstly, because the current imbalance is about 15 per cent and secondly, because balance is restored as soon as running conditions are attained.

The quantitative relationships between the motor current, line current, and torque developed can be understood from Fig.35.20.

In Fig 35.20 (a) is shown the case when the motor is direct-switched to lines. The motor current is, say, 5 times the full-load current. If  $V$  is the line voltage, then voltage/phase across motor is  $V/\sqrt{3}$ .

$$\therefore I_{sc} = 5 I_f = \frac{V}{\sqrt{3}Z} \text{ where } Z \text{ is stator impedance/phase.}$$

In the case of auto-transformer, if a tapping of transformation ratio  $K$  is used, then phase voltage across motor is  $KV/\sqrt{3}$ , as marked in Fig. 35.20 (b).

$$\therefore \text{ motor current at starting } I_2 = \frac{KV}{\sqrt{3}Z} = K \cdot \frac{V}{\sqrt{3}Z} = K \cdot I_{sc} = K \cdot 5 I_f$$

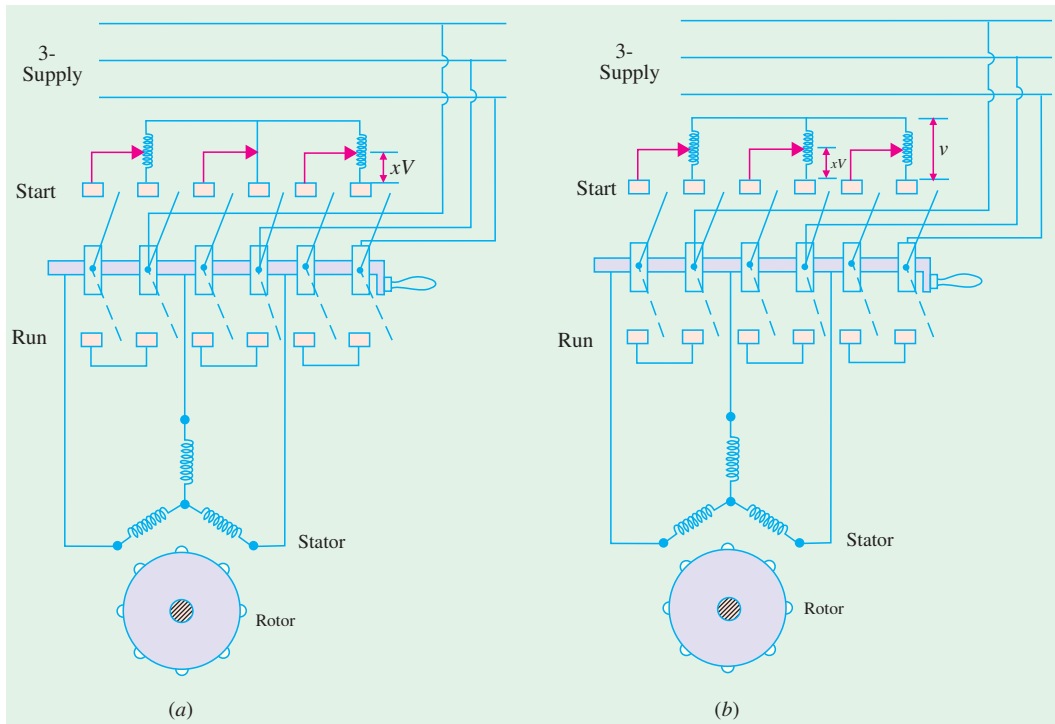

Fig. 35.19

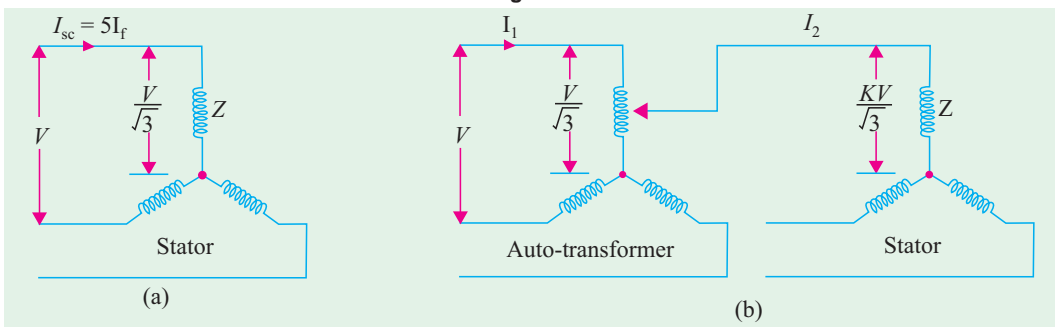

Fig. 35.20

The current taken from supply or by auto-transformer is  $I_1 = K I_2 = K^2 \times 5 I_f = K^2 I_{sc}$  if magnetising current of the transformer is ignored. Hence, we find that although motor current per phase is reduced only  $K$  times the direct-switching current ( $\because K < 1$ ), the current taken by the line is reduced  $K^2$  times.

Now, remembering that torque is proportional to the square of the voltage, we get

$$\begin{aligned} \text{With direct-switching, } T_1 &\propto (V/\sqrt{3})^2; & \text{With auto-transformer, } T_2 &\propto (KV/\sqrt{3})^2 \\ \therefore T_2/T_1 &= (KV/\sqrt{3})^2/(V/\sqrt{3})^2 & \text{or } T_2 &= K^2 T_1 & \text{or } T_{st} &= K^2 \cdot T_{sc} \\ \therefore \text{torque with auto-starter} & & & & & = K^2 \times \text{torque with direct-switching.} \end{aligned}$$

**Relation Between Starting and F.L. Torque**

It is seen that voltage across motor phase on direct-switching is  $V/\sqrt{3}$  and starting current is  $I_{st} = I_{sc}$ . With auto-starter, voltage across motor phase is  $KV/\sqrt{3}$  and  $I_{st} = K I_{sc}$ .

$$\begin{aligned} \text{Now, } T_{st} &\propto I_{st}^2 (s=1) & \text{and } T_f &\propto \frac{I_f^2}{s_f} \\ \therefore \frac{T_{st}}{T_f} &= \left(\frac{I_{st}}{I_f}\right)^2 s_f & \text{or } \frac{T_{st}}{T_f} &= K^2 \left(\frac{I_{sc}}{I_f}\right)^2 s_f = K^2 \cdot a^2 \cdot s_f & (\because I_{st} = K I_{sc}) \end{aligned}$$

Note that this expression is similar to the one derived in Art. 34.11. (a) except that  $x$  has been replaced by transformation ratio  $K$ .

**Example 35.10.** Find the percentage tapping required on an auto-transformer required for a squirrel-cage motor to start the motor against 1/4 of full-load torque. The short-circuit current on normal voltage is 4 times the full-load current and the full-load slip is 3%.

**Solution.**

$$\frac{T_{st}}{T_f} = \frac{1}{4}, \quad \frac{I_{sc}}{I_f} = 4, \quad s_f = 0.03$$

$$\therefore \text{Using } \frac{T_{st}}{T_f} = K^2 \left(\frac{I_{sc}}{I_f}\right)^2 s_f, \text{ we get } \frac{1}{4} = K^2 \times 4^2 \times 0.03$$

$$\therefore K^2 = \frac{1}{64 \times 0.03} \quad \therefore K = 0.722 \text{ or } K = 72.2\%$$

**Example 35.11.** A 20 h.p. (14.92 kW), 400-V, 950 r.p.m., 3- $\phi$ , 50-Hz, 6-pole cage motor with 400 V applied takes 6 times full-load current at standstill and develops 1.8 times full-load running torque. The full-load current is 30 A.

- (a) what voltage must be applied to produce full-load torque at starting ?
  - (b) what current will this voltage produce ?
  - (c) if the voltage is obtained by an auto-transformer, what will be the line current ?
  - (d) if starting current is limited to full-load current by an auto-transformer, what will be the starting torque as a percentage of full-load torque ?
- Ignore the magnetising current and stator impedance drops.

**Solution.** (a) Remembering that  $T \propto V^2$ , we have

In the first case,  $1.8 T_f \propto 400^2$ ; ; In the second case,  $T_f \propto V^2$

$$\therefore \left(\frac{V}{400}\right)^2 = \frac{1}{1.8} \text{ or } V = \frac{400}{\sqrt{1.8}} = 298.1 \text{ V}$$

(b) Currents are proportional to the applied voltage.

$$\therefore 6 I_f \propto 400; I \propto 298.1 \quad \therefore I = 6 \times \frac{298.1}{400}, I_f = \frac{6 \times 298.1 \times 30}{400} = 134.2 \text{ A}$$

(c) Here  $K = 298.1/400$   
 Line current =  $K^2 I_{sc} = (298.1/400)^2 \times 6 \times 30 = 100 \text{ A}$

(d) We have seen in Art. 33.11 (b) that line current =  $K^2 I_{sc}$   
 Now, line current = full-load current  $I_f$  (given)  
 $\therefore 30 = K^2 \times 6 \times 30 \quad \therefore K^2 = 1/6$

Now, using  $\frac{T_{st}}{T_f} = K^2 \left( \frac{I_{sc}}{I_f} \right)^2 \times s_f$  we get  $\frac{T_{st}}{T_f} = \frac{1}{6} \times \left( \frac{6I_f}{I_f} \right)^2 \times 0.05 = 0.3$

Here  $N_s = 120 \times 50/6 = 1000 \text{ r.p.m.}$   $N = 950 \text{ r.p.m.}; s_f = 50/1000 = 0.05$   
 $\therefore T_{st} = 0.3 T_f$  or **30% F.L. torque**

**Example 35.12.** Determine the suitable auto-transformation ratio for starting a 3-phase induction motor with line current not exceeding three times the full-load current. The short-circuit current is 5 times the full-load current and full-load slip is 5%.

Estimate also the starting torque in terms of the full-load torque.

(Elect. Engg.II, Bombay Univ. 1987)

**Solution.** Supply line current =  $K^2 I_{sc}$

It is given that supply line current at start equals  $3 I_f$  and short-circuit current  $I_{sc} = 5 I_f$  where  $I_f$  is the full-load current

$\therefore 3 I_f = K^2 \times 5 I_f$  or  $K^2 = 0.6 \quad \therefore K = 0.775$  or **77.5%**

In the case of an auto starter,

$\frac{T_{st}}{T_f} = K^2 \left( \frac{I_{sc}}{I_f} \right)^2 \times s_f \quad \therefore \frac{T_{st}}{T_f} = 0.6 \times \left( \frac{5 I_f}{I_f} \right)^2 \times 0.05 = 0.75$

$\therefore T_{st} = 0.75 T_f = \mathbf{75\%}$  of full-load torque.

**Example 35.13.** The full-load slip of a 400-V, 3-phase cage induction motor is 3.5% and with locked rotor, full-load current is circulated when 92 volt is applied between lines. Find necessary tapping on an auto-transformer to limit the starting current to twice the full-load current of the motor. Determine also the starting torque in terms of the full-load torque.

(Elect. Machines, Bangalore Univ. 1991)

**Solution.** Short-circuit current with full normal voltage applied is

$I_{sc} = (400/92) I_f = (100/23) I_f$

Supply line current =  $I_{st} = 2 I_f$

Now, line current  $I_{st} = K^2 I_{sc}$

$\therefore 2 I_f = K^2 \times (100/23) I_f \quad \therefore K^2 = 0.46 ; K = 0.678$  or **67.8%**

Also,  $\frac{T_{st}}{T_f} = K^2 \left( \frac{I_{sc}}{I_f} \right)^2 \times s_f = 0.46 \times (100/23)^2 \times 0.035 = 0.304$

$\therefore T_{st} = \mathbf{30.4\%}$  of full-load torque

### Tutorial Problems 35.2

1. A 3- $\phi$  motor is designed to run at 5% slip on full-load. If motor draws 6 times the full-load current at starting at the rated voltage, estimate the ratio of starting torque to the full-load torque.

[1.8] (Electrical Engineering Grad, I.E.T.E. Dec. 1986)

2. A squirrel-cage induction motor has a short-circuit current of 4 times the full-load value and has a full-load slip of 5%. Determine a suitable auto-transformer ratio if the supply line current is not to

exceed twice the full-load current. Also, express the starting torque in terms of the full-load torque. Neglect magnetising current. [70.7%, 0.4]

3. A 3- $\phi$ , 400-V, 50-Hz induction motor takes 4 times the full-load current and develops twice the full-load torque when direct-switched to 400-V supply. Calculate in terms of full-load values (a) the line current, the motor current and starting torque when started by an auto-starter with 50% tap and (b) the voltage that has to be applied and the motor current, if it is desired to obtain full-load torque on starting. [(a) 100%, 200%, 50% (b) 228 V, 282%]

(c) Star-delta Starter

This method is used in the case of motors which are built to run normally with a delta-connected stator winding. It consists of a two-way switch which connects the motor in star for starting and then in delta for normal running. The usual connections are shown in Fig. 35.21. When star-connected, the applied voltage over each motor phase is reduced by a factor of  $1/\sqrt{3}$  and hence the torque developed becomes  $1/3$  of that which would have been developed if motor were directly connected in delta. The line current is reduced to  $1/3$ . Hence, during starting period when motor is Y-connected, it takes  $1/3$ rd as much starting current and develops  $1/3$ rd as much torque as would have been developed were it directly connected in delta.

Relation Between Starting and F.L. Torque

$$I_{st} \text{ per phase} = \frac{1}{\sqrt{3}} I_{sc} \text{ per phase}$$

Fig. 35.21

where  $I_{sc}$  is the current/phase which  $\Delta$ -connected motor would have taken if switched on to the supply directly (however, line current at start =  $1/3$  of line  $I_{sc}$ )

$$\begin{aligned} \text{Now} \quad T_{st} &\propto I_{st}^2 & (s = 1) & & \text{--- Art. 35.10} \\ T_f &\propto I_f^2/s_f \end{aligned}$$

$$\therefore \frac{T_{st}}{T_f} = \left(\frac{I_{st}}{I_f}\right)^2 s_f = \left(\frac{I_{sc}}{\sqrt{3}I_f}\right)^2 s_f = \frac{1}{3} \left(\frac{I_{sc}}{I_f}\right)^2 s_f = \frac{1}{3} a^2 s_f$$

Here,  $I_{st}$  and  $I_{sc}$  represent phase values.

*It is clear that the star-delta switch is equivalent\* to an auto-transformer of ratio  $1/\sqrt{3}$  or 58% approximately.*

This method is cheap and effective provided the starting torque is required not to be more than 1.5 times the full-load torque. Hence, it is used for machine tools, pumps and motor-generators etc.

**Example 35.14.** The full-load efficiency and power factor of a 12-kW, 440-V, 3-phase induction motor are 85% and 0.8 lag respectively. The blocked rotor line current is 45 A at 220 V. Calculate the ratio of starting to full-load current, if the motor is provided with a star-delta starter. Neglect magnetising current. (Elect. Machines, A.M.I.E. Sec. B, 1991)

**Solution.** Blocked rotor current with full voltage applied

$$I_{sc} = 45 \times 440/220 = 90 \text{ A}$$

$$\text{Now, } \sqrt{3} \times 440 \times I_f \times 0.8 = 12,000/0.85, \quad \therefore I_f = 23.1 \text{ A}$$

$$\text{In star-delta starter, } I_{st} = I_{sc}/\sqrt{3} = 90/\sqrt{3} = 52 \text{ A}$$

$$\therefore I_{st}/I_f = 52/23.1 = \mathbf{2.256}$$

**Example 35.15.** A 3-phase, 6-pole, 50-Hz induction motor takes 60 A at full-load speed of 940 r.p.m. and develops a torque of 150 N-m. The starting current at rated voltage is 300 A. What is the starting torque? If a star/delta starter is used, determine the starting torque and starting current. (Electrical Machinery-II, Mysore Univ. 1988)

**Solution.** As seen from Art. 33.10, for direct-switching of induction motors

$$\frac{T_{st}}{T_f} = \left(\frac{I_{sc}}{I_f}\right)^2 s_f \quad \text{Here, } I_{st} = I_{sc} = 300 \text{ A (line value)} ; I_f = 60 \text{ A (line value),}$$

$$s_f = (1000 - 940)/1000 = 0.06 ; T_f = 150 \text{ N-m}$$

$$\therefore T_{st} = 150(300/60)^2 \times 0.06 = \mathbf{225 \text{ N-m}}$$

**When star/delta starter is used**

$$\text{Starting current} = 1/3 \times \text{starting current with direct starting} = 300/3 = \mathbf{100 \text{ A}}$$

$$\text{Starting torque} = 225/3 = \mathbf{75 \text{ N-m}} \quad \text{--- Art 35-11 (c)}$$

**Example 35.16.** Determine approximately the starting torque of an induction motor in terms of full-load torque when started by means of (a) a star-delta switch (b) an auto-transformer with 70.7% tapping. The short-circuit current of the motor at normal voltage is 6 times the full-load current and the full-load slip is 4%. Neglect the magnetising current. (Electrotechnics, M.S. Univ. Baroda 1986)

$$\text{Solution. (a)} \quad \frac{T_{st}}{T_f} = \frac{1}{3} \left(\frac{I_{sc}}{I_f}\right)^2 s_f = \frac{1}{3} \times 6^2 \times 0.04 = 0.48$$

$$\therefore T_{st} = 0.48 T_f \quad \text{or } \mathbf{48\% \text{ of F.L. value}}$$

$$\text{(b) Here } K = 0.707 = 1/\sqrt{2} ; K^2 = 1/2$$

\* By comparing it with the expression given in Art. 35.11 (b)

Now, 
$$\frac{T_{st}}{T_f} = K^2 \left( \frac{I_{sc}}{I_f} \right)^2 s_f = \frac{1}{2} \times 6^2 \times 0.04 = 0.72$$

$\therefore T_{st} = 0.72 T_f$  or **72% of  $T_f$**

**Example 35.17.** A 15 h.p. (11.2 kW), 3- $\phi$ , 6-pole, 50-HZ, 400-V,  $\Delta$ -connected induction motor runs at 960 r.p.m. on full-load. If it takes 86.4 A on direct starting, find the ratio of starting torque to full-load torque with a star-delta starter. Full-load efficiency and power factor are 88% and 0.85 respectively.

**Solution.** Here,  $I_{sc}/\text{phase} = 86.4/\sqrt{3}$  A

$$I_{st} \text{ per phase} = \frac{1}{\sqrt{3}} \cdot I_{sc} \text{ per phase} = \frac{86.4}{\sqrt{3} \times \sqrt{3}} = 28.8 \text{ A}$$

Full-load input line current may be found from

$$\sqrt{3} \times 400 \times I_L \times 0.85 = 11.2 \times 10^3/0.88 \quad \therefore \text{Full-load } I_L = 21.59 \text{ A}$$

$$\text{F.L. } I_{ph} = 21.59/\sqrt{3} \text{ A}; \quad I_f = 21.59/\sqrt{3} \text{ A per phase}$$

$$N_s = 120 \times 50/6 = 1000 \text{ r.p.m.}, \quad N = 950; s_f = 0.05$$

$$\frac{T_{st}}{T_f} = \left( \frac{I_{st}}{I_f} \right)^2 s_f = \left( \frac{28.8 \times \sqrt{3}}{21.59} \right)^2 \times 0.05 \quad \therefore T_{st} = 0.267 T_f \text{ or } \mathbf{26.7\% \text{ F.L. torque}}$$

**Example 35.18.** Find the ratio of starting to full-load current in a 10 kW (output), 400-V, 3-phase induction motor with star/delta starter, given that full-load p.f. is 0.85, the full-load efficiency is 0.88 and the blocked rotor current at 200 V is 40 A. Ignore magnetising current.

(Electrical Engineering, Madras Univ. 1985)

**Solution.** F.L. line current drawn by the  $\Delta$ -connected motor may be found from

$$\sqrt{3} \times 400 \times I_L \times 0.85 = 10 \times 1000/0.88 \quad \therefore I_L = 19.3 \text{ A}$$

Now, with 200 V, the line value of S.C. current of the  $\Delta$ -connected motor is 40 A. If full normal voltage were applied, the line value of S.C. current would be =  $40 \times (400/200) = 80$  A.

$$\therefore I_{sc} \text{ (line value)} = 80 \text{ A}; \quad I_{sc} \text{ (phase value)} = 80/\sqrt{3} \text{ A}$$

When connected in star across 400 V, the starting current per phase drawn by the motor stator during starting is

$$I_{st} \text{ per phase} = \frac{1}{\sqrt{3}} \times I_{sc} \text{ per phase} = \frac{1}{\sqrt{3}} \times \frac{80}{\sqrt{3}} = \frac{80}{3} \text{ A} \quad \text{— Art. 35.10}$$

Since during starting, motor is star-connected,  $I_{st}$  per phase = line value of  $I_{sc} = 80/3$  A

$$\therefore \frac{\text{line value of starting current}}{\text{line value of F.L. current}} = \frac{80/3}{19.3} = \mathbf{1.38}$$

**Example 35.19.** A 5 h.p. (3.73 kW), 400-V, 3- $\phi$ , 50-Hz cage motor has a full-load slip of 4.5%. The motor develops 250% of the rated torque and draws 650% of the rated current when thrown directly on the line. What would be the line current, motor current and the starting torque if the motor were started (i) by means of a star/delta starter and (ii) by connecting across 60% taps of a starting compensator. (Elect. Machines-II, Indore Univ. 1989)

**Solution. (i)** Line current =  $(1/3) \times 650 = \mathbf{216.7\%}$

Motor being star-connected, line current is equal to phase current.

$$\therefore \text{motor current} = 650/3 = \mathbf{216.7\%}$$

As shown earlier, starting torque developed for star-connection is one-third of that developed on direct switching with delta-connection  $\therefore T_{st} = 250/3 = \mathbf{83.3\%}$

**(ii)** Line current =  $K^2 \times I_{sc} = (60/100)^2 \times 650 = \mathbf{234\%}$

$$\begin{aligned}\text{Motor current} &= K \times I_{sc} = (60/100) \times 650 = \mathbf{390\%} \\ T_{st} &= K^2 \times T_{sc} = (60/100)^2 \times 250 = \mathbf{90\%}\end{aligned}$$

**Example. 35.20.** A squirrel-cage type induction motor when started by means of a star/delta starter takes 180% of full-load line current and develops 35% of full-load torque at starting. Calculate the starting torque and current in terms of full-load values, if an auto-transformer with 75% tapping were employed. (Utilization of Elect. Power, A.M.I.E. 1987)

**Solution.** With star-delta starter,  $\frac{T_{st}}{T_f} = \frac{1}{3} \left( \frac{I_{sc}}{I_f} \right)^2 s_f$

Line current on line-start  $I_{sc} = 3 \times 180\%$  of  $I_f = 3 \times 1.8 I_f = 5.4 I_f$

Now,  $T_{st}/T_f = 0.35$  (given);  $I_{sc}/I_f = 5.4$

$\therefore 0.35 = (1/3) \times 5.4^2 s_f$  or  $5.4^2 s_f = 1.05$

**Autostarter :** Here,  $K = 0.75$

Line starting current  $= K^2 I_{sc} = (0.75)^2 \times 5.4 I_f = \mathbf{3.04 I_f = 304\% \text{ of F.L. current}}$

$$\begin{aligned}\frac{T_{st}}{T_f} &= K^2 \left( \frac{I_{sc}}{I_f} \right)^2 s_f; \quad \frac{T_{st}}{T_f} = (0.75)^2 \times 5.4^2 s_f \\ &= (0.75)^2 \times 1.05 = 0.59\end{aligned}$$

$T_{st} = 0.59 T_f = \mathbf{59\% \text{ F.L. torque}}$

**Example. 35.21.** A 10 h.p. (7.46 kW) motor when started at normal voltage with a star-delta switch in the star position is found to take an initial current of  $1.7 \times$  full-load current and gave an initial starting torque of 35% of full-load torque. Explain what happens when the motor is started under the following conditions : (a) an auto-transformer giving 60% of normal voltage (b) a resistance in series with the stator reducing the voltage to 60% of the normal and calculate in each case the value of starting current and torque in terms of the corresponding quantities at full-load. (Elect. Machinery-III, Kerala Univ. 1987)

**Solution.** If the motor were connected in delta and direct-switched to the line, then it would take a line current three times that which it takes when star-connected.

$\therefore$  line current on line start or  $I_{sc} = 3 \times 1.7 I_f = 5.1 I_f$

We know  $\frac{T_{st}}{T_f} = \frac{1}{3} \left( \frac{I_{sc}}{I_f} \right)^2 s_f$

Now  $\frac{T_{st}}{T_f} = 0.35$  ...given;  $\frac{I_{sc}}{I_f} = 5.1$  ...calculated

$\therefore 0.35 = (1/3) \times 5.1^2 \times s_f$

We can find  $s_f$  from  $5.1^2 \times s_f = 1.05$

(a) When it is started with an auto-starter, then  $K = 0.6$

Line starting current  $= K^2 \times I_{sc} = 0.6^2 \times 5.1 I_f = \mathbf{0.836 I_f}$

$T_{st}/T_f = 0.6^2 \times 5.1^2 \times s_f = 0.6^2 \times 1.05 = 0.378$   $\therefore T_{st} = \mathbf{37.8\%}$  of F.L. torque

(b) Here, voltage across motor is reduced to 60% of normal value. In this case motor current is the same as line current but it decreases in proportion to the decrease in voltage.

As voltage across motor  $= 0.6$  of normal voltage

$\therefore$  line starting current  $= 0.6 \times 5.1 I_f = \mathbf{3.06 I_f}$

Torque at starting would be the same as before.

$T_{st}/T_f = 0.6^2 \times 5.1^2 \times s_f = 0.378$   $\therefore T_{st} = \mathbf{37.8\%}$  of F.L. torque.

**Tutorial Problems 35.3**

1. A 3-phase induction motor whose full-load slip is 4 per cent, takes six times full-load current when switched directly on to the supply. Calculate the approximate starting torque in terms of the full-load torque when started by means of an auto-transformer starter, having a 70 percent voltage tap. [0.7  $T_f$ ]
2. A 3-phase, cage induction motor takes a starting current at normal voltage of 5 times the full-load value and its full-load slip is 4 per cent. What auto-transformer ratio would enable the motor to be started with not more than twice full-load current drawn from the supply ?  
What would be the starting torque under these conditions and how would it compare with that obtained by using a stator resistance starter under the same limitations of line current ?  
[63.3% tap ; 0.4  $T_f$  ; 0.16  $T_f$ ]
3. A 3-phase, 4-pole, 50-Hz induction motor takes 40 A at a full-load speed of 1440 r.p.m. and develops a torque of 100 N-m at full-load. The starting current at rated voltage is 200 A. What is the starting torque ? If a star-delta starter is used, what is the starting torque and starting current ? Neglect magnetising current.  
[100 N-m; 33.3 N-m; 66.7 A] (Electrical Machines-IV, Bangalore Univ. Aug. 1978)
4. Determine approximately the starting torque of an induction motor in terms of full-load torque when started by means of (a) a star-delta switch (b) an auto-transformer with 50% tapping. Ignore magnetising current. The short-circuit current of the motor at normal voltage is 5 times the full-load current and the full-load slip is 4 per cent. [(a) 0.33 (b) 0.25] (A.C. Machines, Madras Univ. 1976)
5. Find the ratio of starting to full-load current for a 7.46 kW, 400-V, 3-phase induction motor with star/delta starter, given that the full-load efficiency is 0.87, the full-load p.f. is 0.85 and the short-circuit current is 15 A at 100 V. [1.37] (Electric Machinery-II, Madras Univ. April 1978)
6. A four-pole, 3-phase, 50-Hz, induction motor has a starting current which is 5 times its full-load current when directly switched on. What will be the percentage reduction in starting torque if (a) star-delta switch is used for starting (b) auto-transformer with a 60 per cent tapping is used for starting ?  
(Electrical Technology-III, Gwalior Univ. Nov. 1917)
7. Explain how the performance of induction motor can be predicted by circle diagram. Draw the circle diagram for a 3-phase, mesh-connected, 22.38 kW, 500-V, 4-pole, 50-Hz induction motor. The data below give the measurements of line current, voltage and reading of two wattmeters connected to measure the input :
 

No load	500 V	8.3 A	2.85 kW	- 1.35 kW
Short circuit	100 V	32 A	- 0.75 kW	2.35 kW

 From the diagram, find the line current, power factor, efficiency and the maximum output.  
[83 A, 0.9, 88%, 50.73 kW] (Electrical Machines-II, Vikram Univ. Ujjan 1977)

**35.12. Starting of Slip-ring Motors**

These motors are practically always started with full line voltage applied across the stator terminals. The value of starting current is adjusted by introducing a variable resistance in the rotor circuit. The controlling resistance is in the form of a rheostat, connected in star (Fig. 35.22), the resistance being gradually cut-out of the rotor circuit, as the motor gathers speed. It has been already shown that by increasing the rotor resistance, not only is the rotor (and hence stator) current reduced at starting, but at the same time, the starting torque is also increased due to improvement in power factor.

The controlling rheostat is either of stud or contactor type and

Slip-ring electric motor

Rheostat

may be hand-operated or automatic. The starter unit usually includes a line switching contactor for the stator along with no-voltage (or low-voltage) and over-current protective devices. There is some form of interlocking to ensure proper sequential operation of the line contactor and the starter. This interlocking prevents the closing of stator contactor unless the starter is 'all in'.

As said earlier, the introduction of additional external resistance in the rotor circuit enables a slip-ring motor to develop a high starting torque with reasonably moderate starting current. Hence, such motors can be started under load. This additional resistance is for starting purpose only. It is gradually cut out as the motor comes up to speed.

Fig. 35.22

The rings are, later on, short-circuited and brushes lifted from them when motor runs under normal conditions.

### 35.13. Starter Steps

Let it be assumed, as usually it is in the case of starters, that (i) the motor starts against a constant torque and (ii) that the rotor current fluctuates between fixed maximum and minimum values of  $I_{2max}$  and  $I_{2min}$  respectively.

In Fig. 35.23 is shown one phase of the 3-phase rheostat  $AB$  having  $n$  steps and the rotor circuit. Let  $R_1, R_2, \dots$  etc. be the total resistances of the rotor circuit on the first, second step...etc. respectively. The resistances  $R_1, R_2, \dots$ , etc. consist of rotor resistance per phase  $r_2$  and the external resistances  $\rho_1, \rho_2, \dots$  etc. Let the corresponding values of slips be  $s_1, s_2, \dots$  etc. at stud No.1, 2...etc. At the commencement of each step, the current is  $I_{2max}$  and at the instant of leaving it, the current is  $I_{2min}$ . Let  $E_2$  be the standstill e.m.f. induced in each phase of the rotor. When the handle touches first stud, the current rises to a maximum value  $I_{2max}$ , so that

$$I_{2max} = \frac{s_1 E_2}{\sqrt{[R_1^2 + (s_1 X_2)^2]}} = \frac{E_2}{\sqrt{[(R_1 / s_1)^2 + X_2^2]}}$$

where

$s_1 =$  slip at starting *i.e.* unity and  $X_2 =$  rotor reactance/phase

Then, *before* moving to stud No. 2, the current is reduced to  $I_{2min}$  and slip changes to  $s_2$  such that

$$I_{2min} = \frac{E_2}{\sqrt{[(R_1/s_2)^2 + X_2^2]}}$$

As we now move to stud No. 2, the speed momentarily remains the same, but current rises to  $I_{2max}$  because some resistance is cut out.

$$\text{Hence, } I_{2max} = \frac{E_2}{\sqrt{[(R_2/s_2)^2 + X_2^2]}}$$

After some time, the current is again reduced to  $I_{2min}$  and the slip changes to  $s_3$  such that

$$I_{2min} = \frac{E_2}{\sqrt{[(R_2/s_3)^2 + X_2^2]}}$$

As we next move over to stud No.3, again current rises to  $I_{2max}$  although speed remains momentarily the same.

$$\therefore I_{2max} = \frac{E_2}{\sqrt{[(R_2/s_3)^2 + X_2^2]}} \quad \text{Similarly } I_{2min} = \frac{E_2}{\sqrt{[(R_3/s_4)^2 + X_2^2]}}$$

At the last stud *i.e.* nth stud,  $I_{2max} = \frac{E_2}{\sqrt{[(r_2/s_{max})^2 + X_2^2]}}$  where  $s_{max}$  = slip under normal running conditions, when external resistance is completely cut out.

It is found from above that

$$I_{2max} = \frac{E_2}{\sqrt{[(R_1/s_1)^2 + X_2^2]}} = \frac{E_2}{\sqrt{[(R_2/s_2)^2 + X_2^2]}} = \dots = \frac{E_2}{\sqrt{[(r_2/s_{max})^2 + X_2^2]}}$$

$$\text{or } \frac{R_1}{s_1} = \frac{R_2}{s_2} = \frac{R_3}{s_3} = \dots = \frac{R_{n-1}}{s_{n-1}} = \frac{R_n}{s_n} = \frac{r_2}{s_{max}} \quad \dots(i)$$

Similarly,

$$I_{2min} = \frac{E_2}{\sqrt{[(R_1/s_2)^2 + X_2^2]}} = \frac{E_2}{\sqrt{[(R_2/s_3)^2 + X_2^2]}} = \dots = \frac{E_2}{\sqrt{[(R_{n-1}/s_{max})^2 + X_2^2]}}$$

$$\text{or } \frac{R_1}{s_2} = \frac{R_2}{s_3} = \frac{R_3}{s_4} = \dots = \frac{R_{n-1}}{s_{max}} \quad \dots(ii)$$

From (i) and (ii), we get

$$\frac{s_2}{s_1} = \frac{s_3}{s_2} = \frac{s_4}{s_3} = \dots = \frac{R_2}{R_1} = \frac{R_3}{R_2} = \frac{R_4}{R_3} = \dots = \frac{r_2}{R_{n-1}} = K \text{ (say)} \quad \dots(iii)$$

Now, from (i) it is seen that  $R_1 = \frac{s_1 \times r_2}{s_{max}}$ .

Now,  $s_1 = 1$  at starting, when rotor is stationary.

$\therefore R_1 = r_2/s_{max}$ . Hence,  $R_1$  becomes known in terms of rotor resistance/phase and normal slip. From (iii), we obtain

$$R_2 = KR_1; R_3 = KR_2 = K^2R_1; R_4 = KR_3 = K^3R_1 \text{ and } r_2 = KR_{n-1} = K^{n-1} \cdot R_1$$

$$\text{or } r_2 = K^{n-1} \cdot \frac{r_2}{s_{max}} \quad \text{(putting the value of } R_1)$$

Fig. 35.23

$K = (s_{max})^{1/n-1}$  where  $n$  is the number of starter studs.

The resistances of various sections can be found as given below :

$$\rho_1 = R_1 - R_2 = R_1 - KR_1 = (1 - K) R_1 ; \rho_2 = R_2 - R_3 = KR_1 - K^2R_1 = K\rho_1$$

$$\rho_3 = R_3 - R_4 = K^2 \rho_1 \text{ etc.}$$

Hence, it is seen from above that if  $s_{max}$  is known for the assumed value  $I_{2max}$  of the starting current, then  $n$  can be calculated.

**Example 35.22.** Calculate the steps in a 5-step rotor resistance starter for a 3 phase induction motor. The slip at the maximum starting current is 2% with slip-ring short-circuited and the resistance per rotor phase is 0.02 Ω.

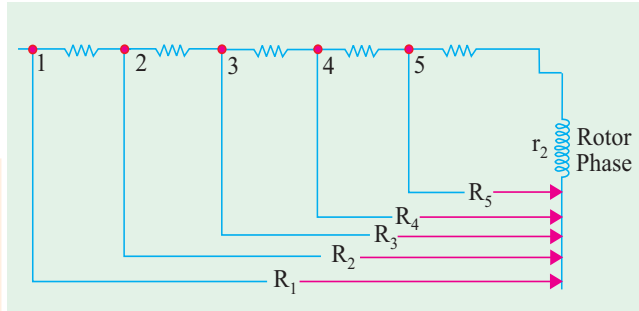

Fig. 35.24

**Solution.** Here,  $s_{max} = 2\%$   
 $= 0.02; r_2 = 0.02 \Omega, n = 6$

$$R_1 = \text{total resistance in rotor circuit/phase on first stud}$$

$$= r_2/s_{max} = 0.02/0.02 = 1 \Omega$$

Now,  $K = (s_{max})^{1/n-1} = (0.02)^{1/5} = 0.4573$

$$R_1 = 1 \Omega; R_2 = KR_1 = 0.4573 \times 1 = 0.4573 \Omega$$

$$R_3 = KR_2 = 0.4573 \times 0.4573 = 0.2091 \Omega; R_4 = KR_3 = 0.4573 \times 0.2091 = 0.0956 \Omega$$

$$R_5 = KR_4 = 0.4573 \times 0.0956 = 0.0437 \Omega; r_2 = KR_5 = 0.4573 \times 0.0437 = 0.02 \Omega \text{ (as given)}$$

The resistances of various starter sections are as found below :

$$\rho_1 = R_1 - R_2 = 1 - 0.4573 = \mathbf{0.5427 \Omega}; \quad \rho_2 = R_2 - R_3 = 0.4573 - 0.2091 = \mathbf{0.2482 \Omega}$$

$$\rho_3 = R_3 - R_4 = 0.2091 - 0.0956 = \mathbf{0.1135 \Omega}; \quad \rho_4 = R_4 - R_5 = 0.0956 - 0.0437 = \mathbf{0.0519 \Omega}$$

$$\rho_5 = R_5 - r_2 = 0.0437 - 0.02 = \mathbf{0.0237 \Omega}$$

The resistances of various sections are shown in Fig. 35.24.

### 35.14. Crawling

It has been found that induction motors, particularly the squirrel-cage type, sometimes exhibit a tendency to run stably at speeds as low as one-seventh of their synchronous speed  $N_s$ . This phenomenon is known as crawling of an induction motor.

This action is due to the fact that the a.c. winding of the stator produces a flux wave, which is not a pure sine wave. It is a complex wave consisting of a fundamental wave, which revolves synchronously and odd harmonics like 3rd, 5th, and 7th etc. which rotate either in the forward or backward direction at  $N_s / 3, N_s / 5$  and  $N_s / 7$  speeds respectively. As a result, in addition to the fundamental torque, harmonic torques are also developed, whose synchronous speeds are  $1/n$ th of the speed for the fundamental torque i.e.  $N_s / n$ , where  $n$  is the order of the harmonic torque. Since 3rd harmonic currents are absent in a balanced 3-phase system, they produce no rotating field and, therefore, no torque. Hence, total motor torque has three components : (i) the fundamental torque, rotating with the synchronous speed  $N_s$  (ii) 5th harmonic torque\* rotating at  $N_s / 5$  speed and (iii) 7th harmonic torque, having a speed of  $N_s / 7$ .

\* The magnitude of the harmonic torques is  $1/n^2$  of the fundamental torque.

Now, the 5th harmonic currents have a phase difference of  $5 \times 120^\circ = 600^\circ = -120^\circ$  in three stator windings. The revolving field, set up by them, rotates in the *reverse* direction at  $N_s / 5$ . The forward speed of the rotor corresponds to a slip greater than 100%. The small amount of 5th harmonic reverse torque produces a braking action and may be neglected.

The 7th harmonic currents in the three stator windings have a phase difference of  $7 \times 120^\circ = 2 \times 360^\circ + 120^\circ = 120^\circ$ . They set up a forward rotating field, with a synchronous speed equal to 1/7th of the synchronous speed of the fundamental torque.

If we neglect all higher harmonics, the resultant torque can be taken as equal to the sum of the fundamental torque and the 7th harmonic torque, as shown in Fig. 35.25. It is seen that the 7th harmonic torque reaches its maximum positive value just before 1/7th synchronous speed  $N_s$ , beyond which it becomes negative in value. Consequently, the resultant torque characteristic shows a dip which may become very pronounced with certain slot combinations. If the mechanical load on the shaft involves a constant load torque, it is possible that the torque developed by the motor may fall below this load torque. When this happens, the motor will not accelerate upto its normal speed but will remain running at a speed, which is nearly 1/7th of its full-speed. This is referred to as crawling of the motor.

Fig. 35.25

35.15. Cogging or Magnetic Locking

Fig. 35.26

Double-cage, 30-kW, 400/440-V, 3-f, 960 r.p.m.

Fig. 35.27

squirrel-cage motor. (Courtesy : Jyoti Ltd., Baroda)

The rotor of a squirrel-cage motor sometimes refuses to start at all, particularly when the voltage is low. This happens when the number of stator teeth  $S_1$  is equal to the number of rotor teeth  $S_2$  and is due to the magnetic locking between the stator and rotor teeth. That is why this phenomenon is sometimes referred to as teeth-locking.

It is found that the reluctance of the magnetic path is minimum when the stator and rotor teeth face each other rather than when the teeth of one element are opposite to the slots on the other. It is in such positions of minimum reluctance, that the rotor tends to remain fixed and thus cause serious trouble during starting. Cogging of squirrel cage motors can be easily overcome by making the number of rotor slots prime to the number of stator slots.

### 35.16. Double Squirrel Cage Motor

The main disadvantage of a squirrel-cage motor is its poor starting torque, because of its low rotor resistance. The starting torque could be increased by having a cage of high resistance, but then the motor will have poor efficiency under normal running conditions (because there will be more rotor Cu losses). The difficulty with a cage motor is that its cage is permanently short-circuited, so no external resistance can be introduced temporarily in its rotor circuit during starting period. Many efforts have been made to build a squirrel-cage motor which should have a high starting torque without sacrificing its electrical efficiency, under normal running conditions. The result is a motor, due to Boucheort, which has two independent cages on the same rotor, one inside the other. A punching for such a double cage rotor is shown in Fig. 35.26.

The **outer** cage consists of bars of a **high-resistance** metal, whereas the inner cage has low-resistance copper bars.

Hence, outer cage has high resistance and low ratio of reactance-to-resistance, whereas the inner cage has low resistance but, being situated deep in the rotor, has a large ratio of reactance-to-resistance. Hence, the outer cage develops maximum torque at starting, while the inner cage does so at about 15% slip.

As said earlier, at starting and at large slip values, frequency of induced e.m.f in the rotor is high. So the reactance of the inner cage ( $= 2\pi f L$ ) and therefore, its impedance are both high. Hence, very little current flows in it. Most of the starting current is confined to outer cage, despite its high resistance. Hence, the motor develops a high starting torque due to high-resistance outer cage. Double squirrel-cage motor is shown in Fig. 35.27.

As the speed increases, the frequency of the rotor e.m.f. decreases, so that the reactance and hence the impedance of inner cage decreases and becomes very small, under normal running conditions. Most of the current then flows through it and hence it develops the greater part of the motor torque.

In fact, when speed is normal, frequency of rotor e.m.f. is so small that the reactance of both cages is practically negligible. The current is carried by two cages in parallel, giving a low combined resistance.

Hence, it has been made possible to construct a single machine, which has a good starting torque

Fig. 35.28

with reasonable starting current and which maintains high efficiency and good speed regulation, under normal operating conditions.

The torque-speed characteristic of a double cage motor may be approximately taken to be the sum of two motors, one having a high-resistance rotor and the other a low-resistance one (Fig. 35.28).

Such motors are particularly useful where frequent starting under heavy loads is required.

### 35.17. Equivalent Circuit

The two rotor cages can be considered in parallel, if it is assumed that both cages completely link the main flux. The equivalent circuit for one phase of the rotor, as referred to stator, is shown in Fig. 35.29. If the magnetising current is neglected, then the figure is simplified to that shown in Fig. 35.30. Hence,  $R'_0/s$  and  $R'_i/s$  are resistances of outer and inner rotors as referred to stator respectively and  $X'_0$  and  $X'_i$  their reactances

Total impedance as referred to primary is given by

$$Z_{01} = R_1 + jX_1 + \frac{1}{1/Z'_1 + 1/Z'_0} = R_1 + jX_1 + \frac{Z'_i Z'_0}{Z'_0 + Z'_i}$$

Fig. 35.29

Fig. 35.30

**Example 35.23.** A double-cage induction motor has the following equivalent circuit parameters, all of which are phase values referred to the primary :

Primary	$R_1 = 1 \Omega$	$X_1 = 3 \Omega$
Outer cage	$R'_0 = 3 \Omega$	$X'_0 = 1 \Omega$
Inner cage	$R'_i = 0.6 \Omega$	$X'_i = 5 \Omega$

The primary is delta-connected and supplied from 440 V. Calculate the starting torque and the torque when running at a slip of 4%. The magnetising current may be neglected.

**Solution.**

Refer to Fig. 35.31

(i) At start,  $s = 1$

$$Z_{01} = 1 + j3 + \frac{1}{1/(3 + j1) + 1/(0.6 + j5)}$$

$$= 2.68 + j4.538 \Omega$$

Current / phase =  $440 / (2.68^2 + 4.538^2)^{1/2} = 83.43 \text{ A}$

Torque =  $3 \times 83.43^2 \times (2.68 - 1)$

= **35,000 synch watt.**

Fig. 35.31

(ii) when  $s = 4$  per cent

In this case, approximate torque may be found by neglecting the outer cage impedance altogether. However, it does carry some current, which is almost entirely determined by its resistance.

$$Z_{01} = 1 + j3 + \frac{1}{1/(3/0.04) + 1/(0.6/0.04 + j5)} = 13.65 + j6.45$$

Current/phase =  $440/(13.65^2 + 6.45^2)^{1/2} = 29.14 \text{ A}$

Torque =  $3 \times 29.14^2 \times (13.65 - 1) = 32,000 \text{ synch watt.}$

**Example 35.24.** At standstill, the equivalent impedance of inner and outer cages of a double-cage rotor are  $(0.4 + j2) \Omega$  and  $(2 + j0.4) \Omega$  respectively. Calculate the ratio of torques produced by the two cages (i) at standstill (ii) at 5% slip. (Elect. Machines-II, Punjab Univ. 1989)

**Solution.** The equivalent circuit for one phase is shown in Fig. 35.32.

(i) At standstill,  $s = 1$

Impedance of inner cage =  $Z_i = \sqrt{0.4^2 + 2^2} = 2.04 \Omega$

Impedance of outer cage =  $Z_o = \sqrt{2^2 + 0.4^2} = 2.04 \Omega$

If  $I_o$  and  $I_i$  are the current inputs of the two cages, then

power input of inner cage,  $P_i = I_i^2 R_i = 0.4 I_i^2$  watt

power input of outer cage,  $P_o = I_o^2 R_o = 2 I_o^2$

$$\begin{aligned} \therefore \frac{\text{torque of outer cage, } T_o}{\text{torque of inner cage, } T_i} &= \frac{P_o}{P_i} = \frac{2 I_o^2}{0.4 I_i^2} = 5 \left( \frac{I_o}{I_i} \right)^2 \\ &= 5 \left( \frac{Z_i}{Z_o} \right)^2 = 5 \left( \frac{2.04}{2.04} \right)^2 = 5 \quad \therefore T_o : T_i :: 5 : 1 \end{aligned}$$

Fig. 35.32

(ii) When  $s = 0.05$

$$Z_o = \sqrt{[(R_o/s)^2 + X_o^2]} = \sqrt{(2/0.05)^2 + 0.4^2} = 40 \Omega$$

$$Z_i = \sqrt{[(R_i/s)^2 + X_i^2]} = \sqrt{(0.4/0.05)^2 + 2^2} = 8.25 \Omega$$

$$\therefore \frac{I_o}{I_i} = \frac{Z_i}{Z_o} = \frac{8.25}{40} = 0.206$$

$$P_o = I_o^2 R_o / s = 40 I_o^2; P_i = I_i^2 R_i / s = 8 I_i^2$$

$$\therefore \frac{T_o}{T_i} = \frac{P_o}{P_i} = \frac{40 I_o^2}{8 I_i^2} = 5 \left( \frac{I_o}{I_i} \right)^2 = 5 (0.206)^2 = 0.21$$

$\therefore T_o : T_i :: 0.21 : 1$

It is seen from above, that the outer cage provides maximum torque at starting, whereas inner cage does so later.

**Example 35.25.** A double-cage rotor has two independent cages. Ignoring mutual coupling between cages, estimate the torque in synchronous watts per phase (i) at standstill and at 5 per cent slip, given that the equivalent standstill impedance of the inner cage is  $(0.05 + j0.4)$  ohm per phase and of the outer cage  $(0.5 + j0.1)$  ohm per phase and that the rotor equivalent induced e.m.f. per phase is 100 V at standstill.

**Solution.** The equivalent circuit of the double-cage rotor is shown in Fig. 35.33.

(i) At standstill,  $s = 1$

The combined impedance of the two cages is

$$Z = \frac{Z_o Z_i}{Z_o + Z_i}$$

where  $Z_0$  = impedance of the outer cage  
 $Z_i$  = impedance of the inner cage  
 $Z = \frac{(0.5 + j 0.1)(0.05 + j 0.4)}{(0.55 + j 0.5)}$

$$= 0.1705 + j 0.191 \text{ ohm}$$

$$\therefore Z = \sqrt{0.1705^2 + 0.191^2} = 0.256 \Omega$$

Rotor current  $I_2 = 100/0.256$  A; Combined resistance  $R_2 = 0.1705 \Omega$

Torque at standstill in synchronous watts per phase is

$$= I_2^2 R_2 = \left(\frac{100}{0.256}\right)^2 \times 0.1705 = \mathbf{26,000 \text{ synch watts}}$$

(ii) Here  $s = 0.05$

$$Z = \frac{\left(\frac{0.5}{0.05} + j 0.1\right)\left(\frac{0.05}{0.05} + j 0.4\right)}{\left(\frac{0.05}{0.5} + \frac{0.5}{0.05} + j 0.5\right)} = 1.01 + j 0.326 \text{ ohm}$$

$$Z = \sqrt{(1.01)^2 + 0.326^2} = 1.06 \Omega$$

Combined resistance  $R_2 = 1.01 \Omega$  ; rotor current =  $100/1.06$  A

Torque in synchronous watts per phase is

$$= I_2^2 R_2 = (100/1.06)^2 \times 1.1 = \mathbf{9,000 \text{ synch.watt.}}$$

**Example 35.26.** In a double-cage induction motor, if the outer cage has an impedance at standstill of  $(2 + j 1.2)$  ohm, determine the slip at which the two cages develop equal torques if the inner cage has an impedance of  $(0.5 + j 3.5)$  ohm at standstill.

(Electric Machines, Osmania Univ. 1991)

**Solution.** Let  $s$  be the slip at which two cage develop equal torques.

Then  $Z_1 = \sqrt{(2/s)^2 + 1.2^2}$  and  $Z_2 = \sqrt{(0.5/s)^2 + 3.5^2}$

$$\therefore \left(\frac{I_1}{I_2}\right)^2 = \left(\frac{Z_2}{Z_1}\right)^2 = \frac{(0.25/s^2) + 3.5^2}{(4/s^2) + 1.44}$$

Power input to outer cage  $P_1 = I_1^2 R_1/s$

$$\therefore P_1 = I_1^2 \times \frac{2}{s}; \quad P_2 = I_2^2 \times \frac{0.5}{s}$$

$$\therefore \frac{T_1}{T_2} = \frac{P_1}{P_2} = \left(\frac{I_1}{I_2}\right)^2 \times 4 = \frac{(0.25/s^2) + 3.5^2}{(4/s^2) + 1.44} \times 4$$

As  $T_1 = T_2$

$$\therefore \frac{4}{s^2} + 1.44 = \left(\frac{0.25}{s^2} + 12.25\right) \times 4 \quad \therefore s = 0.251 = \mathbf{25.1\%}$$

**Example 35.27.** The resistance and reactance (equivalent) values of a double-cage induction motor for stator, outer and inner cage are 0.25, 1.0 and 0.15 ohm resistance and 3.5, zero and 3.0 ohm reactance respectively. Find the starting torque if the phase voltage is 250 V and the synchronous speed is 1000 r.p.m. (I.E.E. London)

**Solution.** The equivalent circuit is shown in Fig. 35.34 where magnetising current has been neglected. At starting,  $s = 1$

Fig. 35.33

Impedance of outer cage  $Z_0' = (1 + j 0)$   
 Impedance of inner cage  $Z_i' = (0.15 + j 3)$

The two impedances are in parallel. Hence, their equivalent impedance

$$Z_2' = \frac{Z_0'Z_i'}{Z_0' + Z_i'} = \frac{(1 + j 0)(0.15 + j 3)}{(1 + j 0) + (0.15 + j 3)}$$

$$= 0.889 + j 0.29$$

Stator impedance =  $(0.25 + j 3.5)$

$\therefore$  total impedance  $Z_{01} = (0.889 + j 0.29) + (0.25 + j 3.5)$   
 $= (1.14 + j 3.79) \Omega$  (approx.)

$$\text{Current } I = \frac{\text{phase voltage}}{\text{total phase impedance}} = \frac{250 + j 0}{1.14 + j 3.79} = 18.2 - j 60.5 = 66.15 \text{ A}$$

Rotor Cu loss/phase = (current)<sup>2</sup> × total resistance/phase of two rotors  
 $= 66.15^2 \times 0.889 = 3,890 \text{ W}$

Total Cu loss in 3-phases =  $3 \times 3890 = 11,670 \text{ W}$

Now, rotor input =  $\frac{\text{rotor Cu loss}}{s}$ ; At starting,  $s = 1 \therefore$  rotor input = 11,670 W

$\therefore T_{start} = 11,670$  synchronous watts

Also  $T_{start} \times 2\pi N_s = 11,670$  or  $T_{start} = \frac{11,670}{2\pi \times (1000/60)} = 111.6 \text{ N-m (approx.)}$

Fig. 35.34

**Note.** If torques developed by the two rotors separately are required, then find  $E_2$  (Fig. 35.34), then  $I_1$  and  $I_2$ . Knowing these values,  $T_1$  and  $T_2$  can be found as given in previous example.

**Example 35.28.** A double-cage induction motor has the following equivalent circuit parameters all of which are phase values referred to the primary :

Primary :  $R_1 = 1 \text{ ohm } X_1 = 2.8 \text{ ohm}$

Outer cage :  $R_0' = 3 \text{ ohm } X_0' = 1.0 \text{ ohm}$

Inner cage :  $R_i' = 0.5 \text{ ohm } X_i' = 5 \text{ ohm}$

The primary is delta-connected and supplied from 440 V. Calculate the starting torque and the torque when running at a slip of 4 per cent. The magnetizing branch can be assumed connected across the primary terminals.

(Electrical Machines-II, South Gujarat Univ. 1987)

Fig. 35.35

**Solution.** The equivalent circuit for one phase is shown in Fig. 35.35. It should be noted that magnetising impedance  $Z_0$  has no bearing on the torque and speed and hence, can be neglected so far as these two quantities are concerned

(i) At standstill  $s = 1$

$$Z_2' = \frac{Z_0'Z_i'}{Z_0' + Z_i'} = \frac{(3 + j1.0)(0.5 + j5)}{(3.5 + j6)}$$

$$= 1.67 + j 1.56$$

$$Z_{01} = Z_1 + Z_2' = (1 + j 2.8) + (1.67 + j 1.56)$$

$$= (2.67 + j 4.36) = 5.1 \angle 58.5^\circ$$

Voltage per phase,  $V_1 = 440$  V. Since stator is delta-connected.

$$I_2' = V_1/Z_{01} = 440/5.1 \angle 58.5^\circ = 86.27 \angle -58.5^\circ$$

Combined resistance  $R_2 = 1.6 \Omega$

$$\therefore \text{starting torque per phase} = I_2'^2 R_2 = 86.27^2 \times 1.67 = \mathbf{12,430 \text{ synch. watt.}}$$

(ii) when  $s = 0.04$

$$Z_0' = (3/0.04) + j 1.0 = 75 + j 1.0; \quad Z_i' = (0.5/0.04) + j 5 = 12.5 + j 5$$

$$Z_2' = \frac{Z_0' Z_i'}{Z_0' + Z_i'} = \frac{(75 + j 1.0)(12.5 + j 5)}{(87.5 + j 6)} = 10.3 + j 3.67$$

$$Z_{01} = Z_1 + Z_2' = (1 + j 2.8) + (10.3 + j 6.47) = 11.3 + j 6.47 = 13.03 \angle 29.8^\circ$$

$$I_2' = V_1/Z_{01} = 440/13.03 \angle 29.8^\circ = 33.76 \angle -29.8^\circ$$

combined resistance  $R_2 = 10.3 \Omega$

$$\therefore \text{full-load torque per phase} = I_2'^2 R_2 = 33.76^2 \times 10.3 = \mathbf{11,740 \text{ synch. watts}}$$

Obviously, starting torque is higher than full-load torque.

### Tutorial Problems 35.4

1. Calculate the steps in a 5-section rotor starter of a 3-phase induction motor for which the starting current should not exceed the full-load current, the full-load slip is 0.018 and the rotor resistance is  $0.015 \Omega$  per phase

$$\rho_1 = 0.46 \Omega; \rho_2 = 0.206 \Omega; \rho_3 = 0.092 \Omega; \rho_4 = 0.042 \Omega; \rho_5 = 0.0185 \Omega$$

(Electrical Machinery-III, Kerala Univ. Apr. 1976)

2. The full-load slip of a 3-phase double-cage induction motor is 6% and the two cages have impedances of  $(3.5 + j 1.5) \Omega$  and  $(0.6 + j 7.0) \Omega$  respectively. Neglecting stator impedances and magnetising current, calculate the starting torque in terms of full-load torque. [79%]
3. In a double-cage induction motor, if the outer cage has an impedance at standstill of  $(2 + j 2)$  ohm and the inner cage an impedance of  $(0.5 + j 5) \Omega$ , determine the slip at which the two cages develop equal torques. [17.7%]
4. The two independent cages of a rotor have the respective standstill impedance of  $(3 + j 1)$  ohm and  $(1 + j 4)$  ohm. What proportion of the total torque is due to the outer cage (a) at starting and (b) at a fractional slip of 0.05? [(a) 83.6% (b) 25.8%] (Principle of Elect. Engg.I, Jadavpur Univ. 1975)
5. An induction motor has a double cage rotor with equivalent impedance at standstill of  $(1.0 + j 1.0)$  and  $(0.2 + j 4.0)$  ohm. Find the relative value of torque given by each cage at a slip of 5%. [(a) 40.1 (b) 0.4 : 1]

(Electrical Machines-I, Gwalior Univ. Nov. 1977)

### 35.18. Speed Control of Induction Motors\*

A 3-phase induction motor is practically a constant-speed machine, more or less like a d.c. shunt motor. The speed regulation of an induction motor (having low resistance) is usually less than 5% at full-load. However, there is one difference of practical importance between the two. Whereas d.c. shunt motors can be made to run at any speed within wide limits, with good efficiency and speed regulation, merely by manipulating a simple field rheostat, the same is not possible with induction motors. In their case, speed reduction is accompanied by a corresponding loss of efficiency and good speed regulation. That is why it is much easier to build a good adjustable-speed d.c. shunt motor than an adjustable speed induction motor.

Different methods by which speed control of induction motors is achieved, may be grouped under two main headings :

---

\* For Electronic Control of AC Motors, please consult the relevant chapter of this book, in vol. III.

**1. Control from stator side**

- (a) by changing the applied voltage                      (b) by changing the applied frequency  
 (c) by changing the number of stator poles

**2. Control from rotor side**

- (d) rotor rheostat control  
 (e) by operating two motors in concatenation or cascade  
 (f) by injecting an e.m.f. in the rotor circuit.

A brief description of these methods would be given below :

**(a) Changing Applied Voltage**

This method, though the cheapest and the easiest, is rarely used because

- (i) a large change in voltage is required for a relatively small change in speed  
 (ii) this large change in voltage will result in a large change in the flux density thereby seriously disturbing the magnetic conditions of the motor.

**(b) Changing the Applied Frequency**

This method is also used very rarely. We have seen that the synchronous speed of an induction motor is given by  $N_s = 120f/P$ . Clearly, the synchronous speed (and hence the running speed) of an induction motor can be changed by changing the supply frequency  $f$ . However, this method could only be used in cases where the induction motor happens to be the only load on the generators, in which case, the supply frequency could be controlled by controlling the speed of the prime movers of the generators. But, here again the range over which the motor speed may be varied is limited by the economical speeds of the prime movers. This method has been used to some extent on electrically-driven ships.

**(c) Changing the Number of Stator Poles**

This method is *easily applicable to squirrel-cage motors* because the squirrel-cage rotor adopts itself to any reasonable number of stator poles.

From the above equation it is also clear that the synchronous (and hence the running) speed of an induction motor could also be changed by changing the number of stator poles. This change of number of poles is achieved by having two or more entirely independent stator windings in the same slots. Each winding gives a different number of poles and hence different synchronous speed. For example, a 36-slot stator may have two 3- $\phi$  windings, one with 4 poles and the other with 6-poles. With a supply frequency of 50-Hz, 4-pole winding will give  $N_s = 120 \times 50/4 = 1500$  r.p.m. and the 6-pole winding will give  $N_s = 120 \times 50/6 = 1000$  r.p.m. Motors with four independent stator winding are also in use and they give four different synchronous (and hence running) speeds. Of course, one winding is used at a time, the others being entirely disconnected.

This method has been used for elevator motors, traction motors and also for small motors driving machine tools.

Speeds in the ratio of 2:1 can be produced by a single winding if wound on the consequent-pole principle. In that case, each of the two stator windings can be connected by a simple switch to give two speeds, each, which means four speeds in all. For example, one stator winding may give 4 or 8-poles and the other 6 or 12-poles. For a supply frequency of 50-Hz, the four speeds will be 1500, 750, 1000 and 500 r.p.m. Another combination, commonly used, is to group 2- and 4-pole winding with a 6- and 12-pole winding, which gives four synchronous speeds of 3000, 1500, 1000 and 500 r.p.m.

**(d) Rotor Rheostat Control**

In this method (Fig. 35.36), which is applicable to slip-ring motors alone, the motor speed is reduced by introducing an external resistance in the rotor circuit. For this purpose, the rotor starter

may be used, provided it is continuously rated. *This method is, in fact, similar to the armature rheostat control method of d.c. shunt motors.*

It has been shown in Art 34.22 that near synchronous speed (i.e. for very small slip value),  $T \propto s/R_2$ .

It is obvious that for a given torque, slip can be increased i.e. speed can be decreased by increasing the rotor resistance  $R_2$ .

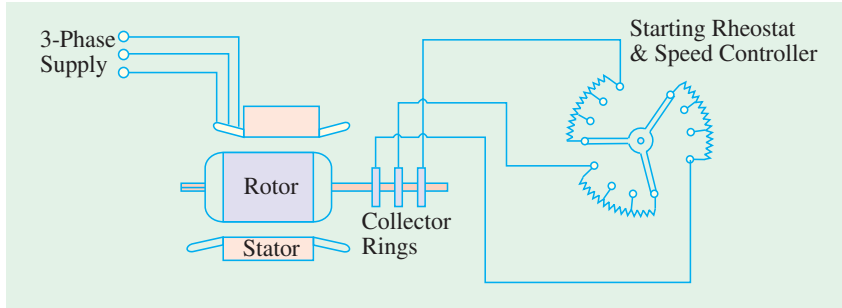

Fig. 35. 36

One serious disadvantage of this method is that with increase in rotor resistance,  $I^2R$  losses also increase which decrease the operating efficiency of the motor. In fact, the loss is directly proportional to the reduction in the speed.

The second disadvantage is the double dependence of speed, not only on  $R_2$  but on load as well.

Because of the wastefulness of this method, it is used where speed changes are needed for short periods only.

**Example 35.29.** The rotor of a 4-pole, 50-Hz slip-ring induction motor has a resistance of 0.30  $\Omega$  per phase and runs at 1440 rpm. at full load. Calculate the external resistance per phase which must be added to lower the speed to 1320 rpm, the torque being the same as before.

(Advanced Elect. Machines AMIE Sec.E1992)

**Solution.** The motor torque is given by  $T = \frac{K s R_2}{R_2^2 + (s X_2)^2}$

Since,  $X_2$  is not given,  $T = \frac{K s R_2}{R_2^2} = \frac{K s}{R_2}$

In the first case,  $T_1 = K s_1 / R_2$ ; in the second case,  $T_2 = K s_2 / (R_2 + r)$

where  $r$  is the external resistance per phase, added to the rotor circuit

Since  $T_1 = T_2 \quad \therefore K s_1 / R_2 = K s_2 / (R_2 + r)$  or  $(R_2 + r) / R_2 = s_2 / s_1$

Now,  $N_s = 120 \times 50 / 4 = 1500$  rpm;  $N_1 = 1440$  rpm;  $N_2 = 1320$  rpm

$\therefore s_1 = (1500 - 1440) / 1500 = 0.04$ ;  $s_2 = (1500 - 1320) / 1500 = 0.12$

$\therefore \frac{0.3 + r}{0.3} = \frac{0.12}{0.04} \quad \therefore r = 0.6 \Omega$

**Example 35.30.** A certain 3-phase, 6-pole, 50-Hz induction motor when fully-loaded, runs with a slip of 3%. Find the value of the resistance necessary in series per phase of the rotor to reduce the speed by 10%. Assume that the resistance of the rotor per phase is 0.2 ohm.

(Electrical Engineering-II (M), Bangalore Univ. 1989)

**Solution.**  $T = \frac{K s R_2}{R_2^2 + (s X_2)^2} = \frac{K_s R_2}{R_2^2} = \frac{K s}{R_2}$  - neglecting  $(s X_2)$

$\therefore T_1 = K s_1 / R_2$  and  $T_2 = K s_2 / (R_2 + r)$  where  $r$  is the external resistance per phase added to the rotor circuit.

Since  $T_1 = T_2, K s_1 / R_2 = K s_2 / (R_2 + r)$  or  $(R_2 + r) / R_2 = s_2 / s_1$

Now,  $N_s = 120 \times 50 / 6 = 1000$  rpm.,  $s_1 = 0.03, N_1 = 1000 (1 - 0.030) = 970$  rpm.

$$N_2 = 970 - 10\% \text{ of } 970 = 873 \text{ rpm.}, s_2 = (1000 - 873)/1000 = 0.127$$

$$\therefore \frac{0.2 + r}{0.2} = \frac{0.127}{0.03}; \quad r = \mathbf{0.65 \Omega}$$

**(e) Cascade or Concatenation or Tandem Operation**

In this method, two motors are used (Fig. 35.37) and are ordinarily mounted on the same shaft, *so that both run at the same speed* (or else they may be geared together).

The stator winding of the main motor A is connected to the mains in the usual way, while that of the auxiliary motor B is fed from the rotor circuit of motor A. For satisfactory operation, the main motor A should be phase-wound *i.e.* of slip-ring type with stator to rotor winding ratio of 1 : 1, so that, in addition to concatenation, each motor may be run from the supply mains separately.

There are at least three ways (and sometimes four ways) in which the combination may be run.

1. Main motor A may be run separately from the supply. In that case, the synchronous speed is  $N_{sa} = 120 f / P_a$  where  $P_a$  = Number of stator poles of motor A.

2. Auxiliary motor B may be run separately from the mains (with motor A being disconnected). In that case, synchronous speed is  $N_{sb} = 120 \times f / P_b$  where  $P_b$  = Number of stator poles of motor B.

3. The combination may be connected in cumulative cascade *i.e.* in such a way that the phase rotation of the stator fields of both motors is in the same direction. The synchronous speed of the cascaded set, in this case, is  $N_{sc} = 120 f / (P_a + P_b)$ .

**Proof**

Let  $N$  = actual speed of concatenated set ;  
 $N_{sa}$  = synchronous speed of motor A, it being independent of  $N$ .

Clearly, the relative speed of rotor A with respect to its stator field is  $(N_{sa} - N)$ . Hence, the frequency  $f'$  of the induced e.m.f. in rotor A is given by

$$f' = \frac{N_{sa} - N}{N_{sa}} \times f$$

*This is also the frequency of the e.m.f. applied to the stator of motor B.* Hence, the synchronous speed of motor B with this input frequency is

$$N' = 120 \frac{f'}{P_b} = \frac{120 (N_{sa} - N) f}{P_b \times N_{sa}} \quad \dots(i)$$

(Note that  $N'$  is not equal to  $N_{sb}$  which is the synchronous speed of motor B with supply frequency  $f$ ).

This will induce an e.m.f. of frequency, say,  $f''$  in the rotor B. Its value is found from the fact that the stator and rotor frequencies are proportional to the speeds of stator field and the rotor

$$\therefore f'' = \frac{N' - N}{N'} f$$

Now, on no-load, the speed of rotor B is almost equal to its synchronous speed, so that the frequency of induced e.m.f. is, to a first approximation, zero.

Fig. 35. 37

$$f'' = 0, \text{ or } \frac{N' - N}{N'} f = 0 \text{ or } N' = N \quad \dots(ii)$$

From (i) above 
$$N' = \frac{120 f (N_{sa} - N)}{P_b \times N_{sa}} = \frac{120 f}{P_b} \left( 1 - \frac{N}{N_{sa}} \right)$$

Hence, from (ii) above,

$$\frac{120 f}{P_b} \left( 1 - \frac{N}{N_{sa}} \right) = N \text{ or } \frac{120 f}{P_b} = N \left( 1 + \frac{1}{N_{sa}} \times \frac{120 f}{P_b} \right)$$

Putting  $N_{sa} = 120 f / P_a$ , we get

$$\frac{120 f}{P_b} = N \left( 1 + \frac{P_a}{120 f} \times \frac{120 f}{P_b} \right) = N \left( 1 + \frac{P_a}{P_b} \right) \therefore N = \frac{120 f}{(P_a + P_b)}$$

Concatenated speed of the set =  $120 f / (P_a + P_b)$

**How the Set Starts ?**

When the cascaded set is started, the voltage at frequency  $f$  is applied to the stator winding of machine  $A$ . An induced e.m.f. of the same frequency is produced in rotor  $A$  which is supplied to auxiliary motor  $B$ . Both the motors develop a forward torque. As the shaft speed rises, the rotor frequency of motor  $A$  falls and so does the synchronous speed of motor  $B$ . The set settles down to a stable speed when the shaft speed becomes equal to the speed of rotating field of motor  $B$ .

Considering load conditions, we find that the electrical power taken in by stator  $A$  is partly used to meet its  $I^2R$  and core losses and the rest is given to its rotor. The power given to rotor is further divided into two parts : one part, proportional to the speed of set *i.e.*  $N$  is converted into mechanical power and the other part proportional to  $(N_{sa} - N)$  is developed as electrical power at the slip frequency, and is passed on to the auxiliary motor  $B$ , which uses it for producing mechanical power and losses. Hence, approximately, the mechanical outputs of the two motors are in the ratio  $N : (N_{sa} - N)$ . **In fact, it comes to that the mechanical outputs are in the ratio of the number of poles of the motors.**

It may be of interest to the reader to know that it can be proved that

(i)  $s = f'' / f$  where  $s$  = slip of the set referred to its synchronous speed  $N_{sc}$ .  
 $= (N_{sc} - N) / N_{sc}$

(ii)  $s = s_a s_b$

where  $s_a$  and  $s_b$  are slips of two motors, referred to their respective stators *i.e.*

$$s_a = \frac{N_{sa} - N}{N_{sa}} \text{ and } s_b = \frac{N' - N}{N}$$

**Conclusion**

We can briefly note the main conclusions drawn from the above discussion :

(a) the mechanical outputs of the two motors are in the ratio of their number of poles.

(b)  $s = f'' / f$  (c)  $s = s_a s_b$

4. The fourth possible connection is the **differential cascade**. In this method, the phase rotation of stator field of the motor  $B$  is opposite to that of the stator of motor  $A$ . This reversal of phase rotation of stator of motor  $B$  is obtained by interchanging any of its two leads. It can be proved in the same way as above, that for this method of connection, the synchronous speed of the set is

$$N_{sc} = 120 f / (P_a - P_b)$$

As the differentially-cascaded set has a very small or zero starting torque, this method is rarely used. Moreover, the above expression for synchronous speed becomes meaningless for  $P_a = P_b$ .

**Example 35.31.** Two 50-Hz, 3- $\phi$  induction motors having six and four poles respectively are cumulatively cascaded, the 6-pole motor being connected to the main supply. Determine the

frequencies of the rotor currents and the slips referred to each stator field if the set has a slip of 2 per cent. (Elect. Machinery-II Madras Univ. 1987)

**Solution.** Synchronous speed of set  $N_{sc} = 120 \times 50/10 = 600$  r.p.m.

Actual rotor speed  $N = (1 - s) N_{sc} = (1 - 0.02) 600 = 588$  r.p.m.

Synchronous speed of the stator field of 6-pole motor,  $N_{sa} = 120 \times 50/6 = 1000$  r.p.m.

Slip referred to this stator field is

$$s_a = \frac{N_{sa} - N}{N_{sa}} = \frac{1000 - 588}{1000} = 0.412 \quad \text{or} \quad \mathbf{41.2\%}$$

Frequency of the rotor currents of 6-pole motor  $f' = s_a f = 0.412 \times 50 = \mathbf{20.6 \text{ Hz}}$

This is also the frequency of stator currents of the four pole motor. The synchronous speed of the stator of 4-pole motor is

$$N' = 120 \times 20.6/4 = 618 \text{ r.p.m.}$$

This slip, as referred to the 4-pole motor, is  $s_b = \frac{N' - N}{N'} = \frac{618 - 588}{618}$

$$= 0.0485 \text{ or } \mathbf{4.85\%}$$

The frequency of rotor current of 4-pole motor is

$$f'' = s_b f' = 0.0485 \times 20.6 = \mathbf{1.0 \text{ Hz (approx)}}$$

As a check,

$$f'' = s f = 0.02 \times 50 = 1.0 \text{ Hz}$$

**Example 35.32.** A 4-pole induction motor and a 6-pole induction motor are connected in cumulative cascade. The frequency in the secondary circuit of the 6-pole motor is observed to be 1.0 Hz. Determine the slip in each machine and the combined speed of the set. Take supply frequency as 50 Hz. (Electrical Machinery-II, Madras Univ. 1986)

**Solution.** With reference to Art. 35.18 (e) and Fig. 35.38

$$N_{sc} = 120 \times 50/(4 + 6) = 600 \text{ r.p.m.}$$

$$s = f''/f = 1/50 = 0.02$$

$N$  = actual speed of the concatenated set

$$\therefore 0.02 = \frac{600 - N}{600} \quad \text{or} \quad N = \mathbf{588 \text{ r.p.m.}}$$

$$N_{sa} = 120 \times 50/4 = 1500 \text{ r.p.m.}$$

$$s_a = (1500 - 588)/1500$$

$$= 0.608 \quad \text{or} \quad \mathbf{60.8\%}$$

$$f' = s_a f = 0.608 \times 50 = 30.4 \text{ Hz}$$

$N'$  = synchronous speed of 6-pole motor with frequency  $f'$

$$= 120 \times 30.4/6 = 608 \text{ r.p.m.}$$

$$s_b = \frac{N' - N}{N'} = \frac{608 - 588}{608} = 0.033 \quad \text{or} \quad \mathbf{3.3\%}$$

Fig. 35.38

**Example 35.33.** The stator of a 6-pole motor is joined to a 50-Hz supply and the machine is mechanically coupled and joined in cascade with a 4-pole motor, Neglecting all losses, determine the speed and output of the 4-pole motor when the total load on the combination is 74.6 kW.

**Solution.** As all losses are neglected, the actual speed of the rotor is assumed to be equal to the synchronous speed of the set.

Now, 
$$N_{sc} = 120 \times 50/10 = \mathbf{600 \text{ r.p.m.}}$$

As said earlier, mechanical outputs are in the ratio of the number of poles of the motors.

∴ output of 4-pole motor =  $74.6 \times 4/10 = 29.84 \text{ kW}$

**Example 35.34.** A cascaded set consists of two motors A and B with 4 poles and 6 poles respectively. The motor A is connected to a 50-Hz supply. Find

(i) the speed of the set

(ii) the electric power transferred to motor B when the input to motor A is 25 kW. Neglect losses. (Electric Machines-I, Utkal Univ. 1990)

**Solution.** Synchronous speed of the set is\*

$$N_{sc} = 120 f / (P_a + P_b) = 120 \times 50 / (6 + 4) = 600 \text{ r.p.m.}$$

(ii) The outputs of the two motors are proportional to the number of their poles.

∴ output of 4-pole motor B =  $25 \times 4/10 = 10 \text{ kW}$

**(f) Injecting an e.m.f. in the Rotor Circuit**

In this method, the speed of an induction motor is controlled by injecting a voltage in the rotor circuit, it being of course, necessary for the injected voltage to have the same frequency as the slip frequency. There is, however, no restriction as to the phase of the injected e.m.f.

When we insert a voltage which is in *phase opposition* to the induced rotor e.m.f., it amounts to increasing the rotor resistance, whereas inserting a voltage which is in phase with the induced rotor e.m.f., is equivalent to *decreasing* its resistance. Hence, by changing the phase of the injected e.m.f. and hence the rotor resistance, the speed can be controlled.

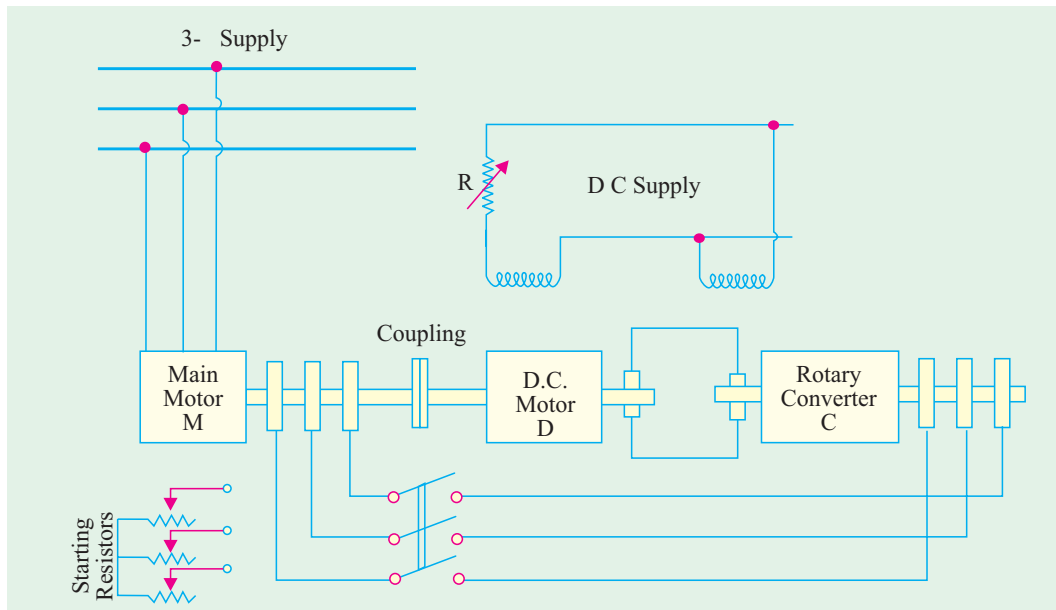

Fig. 35.39

One such practical method of this type of speed control is Kramer system, as shown in Fig. 35.39, which is used in the case of large motors of 4000 kW or above. It consists of a rotary converter C which converts the low-slip frequency a.c. power into d.c. power, which is used to drive a d.c. shunt motor D, mechanically coupled to the main motor M.

The main motor is coupled to the shaft of the d.c. shunt motor D. The slip-rings of M are connected to those of the rotary converter C. The d.c. output of C is used to drive D. Both C and D

\* It is assumed that the two motors are connected in cumulative cascade.

are excited from the d.c. bus-bars or from an exciter. There is a field regulator which governs the back e.m.f.  $E_b$  of  $D$  and hence the d.c. potential at the commutator of  $C$  which further controls the slip-ring voltage and therefore, the speed of  $M$ .

One big advantage of this method is that any speed, within the working range, can be obtained instead of only two or three, as with other methods of speed control.

Yet another advantage is that if the rotary converter is over-excited, it will take a leading current which compensates for the lagging current drawn by main motor  $M$  and hence improves the power factor of the system.

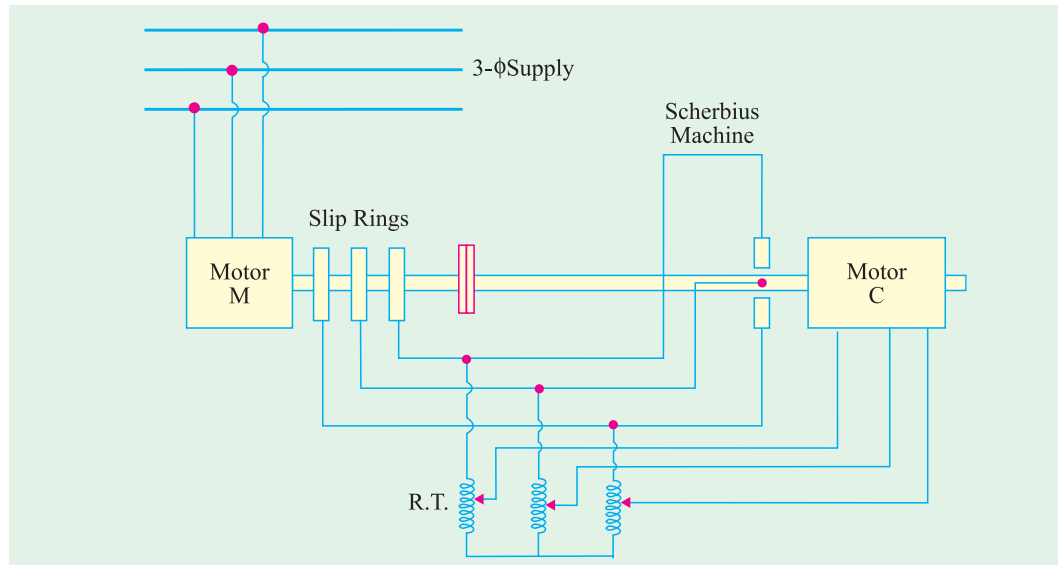

Fig. 35.40

In Fig. 35.40 is shown another method, known as Scherbius system, for controlling the speed of large induction motors. The slip energy is not converted into d.c. and then fed to a d.c. motor, rather it is fed directly to a special 3-phase (or 6-phase) a.c. commutator motor-called a, Scherbius machine.

The polyphase winding of machine  $C$  is supplied with the low-frequency output of machine  $M$  through a regulating transformer  $RT$ . The commutator motor  $C$  is a variable-speed motor and its speed (and hence that of  $M$ ) is controlled by either varying the tapings on  $RT$  or by adjusting the position of brushes on  $C$ .

### Tutorial Problems 35.5

1. An induction motor has a double-cage rotor with equivalent impedances at standstill of  $(1.0 + j 1.0)$  and  $(0.2 + j 4.0) \Omega$ . Find the relative values of torque given by each cage (a) at starting and (b) at 5 % slip [(a) 40:1 (b) 0.4:1] *(Adv. Elect. Machines AMIE Sec. B 1991)*
2. The cages of a double-cage induction motor have standstill impedances of  $(3.5 + j 1.5) \Omega$  and  $(0.6 + j 7.0) \Omega$  respectively. The full-load slip is 6%. Find the starting torque at normal voltage in terms of full-load torque. Neglect stator impedance and magnetizing current. [300%] *(Elect. Machines-I, Nagpur Univ. 1993)*
3. The rotor of a 4 pole, 50 Hz, slip ring induction motor has a resistance of 0.25 ohm per phase and runs at 1440 rpm at full-load. Calculate the external resistance per phase, which must be added to lower the speed to 1200 rpm, the torque being same as before. [1  $\Omega$ ] *(Utilisation of Electric Power (E-8) AMIE Sec. B Summer 1992)*

### 35.19. Three-phase A.C. Commutator Motors

Such motors have shunt speed characteristics *i.e.* change in their speed is only moderate, as compared to the change in the load. They are ideally suited for drives, requiring a uniform accelerating torque and continuously variable speed characteristics over a wide range. Hence, they find wide use in high-speed lifts, fans and pumps and in the drives for cement kilns, printing presses, pulverised fuel plants, stokers and many textile machines. Being more complicated, they are also more expensive than single-speed motors. Their efficiency is high over the whole speed range and their power factor varies from low value at synchronous speed to unity at maximum (supersynchronous) speed.

The speed control is obtained by injecting a variable voltage at **correct** frequency into the secondary winding of the motor via its commutator. If injected voltage assists the voltage induced in the secondary winding, the speed is increased but if it is in the opposing direction, then motor speed is reduced. The commutator acts as a frequency changer because it converts the supply frequency of the regulating voltage to the slip frequency corresponding to the speed required.

Following are the two principal types of such motors :

- (i) Schrage or rotor-fed or brush shift motor and (ii) stator-fed or induction-regulator type motor.

### 35.20. Schrage Motor\*

It is a rotor-fed, shunt-type, brush-shifting, 3-phase commutator induction motor which has built-in arrangement both for **speed control and power factor improvement**. In fact, it is an induction motor with a built-in slip-regulator. It has **three** windings: two in rotor and one in stator as shown in Fig. 35.41 and 35.42 (a) The three windings are as under:

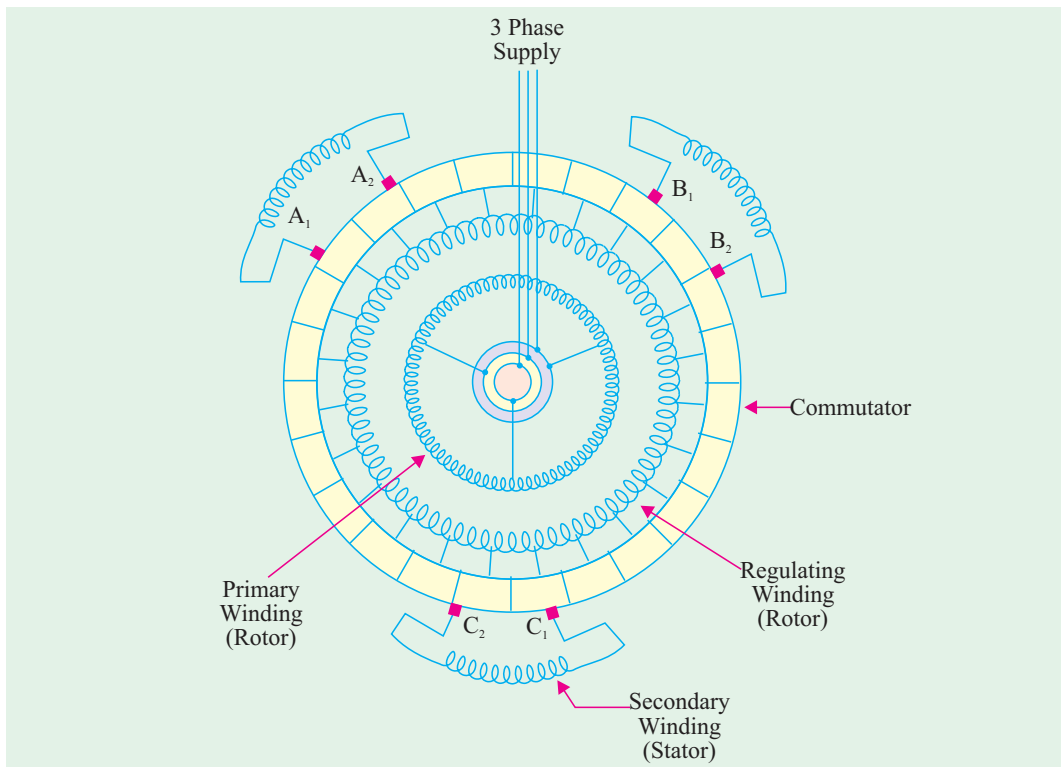

Fig. 35.41

- (i) **Primary winding.** It is housed in the lower part of the rotor slots (not stator) and is supplied through slip-rings and brushes at **line** frequency. It generates the working flux in the machine.

---

\* After the name of its inventor K.H. Schrage of Sweden.

(ii) **Regulating winding.** It is variously known as **compensating** winding or **tertiary** winding. It is also housed in **rotor slots** (in the upper part) and is connected to the commutator in a manner similar to the armature of a d.c. motor.

(iii) **Secondary winding.** It is contained in the **stator slots**, but end of each phase winding is connected to one of the pair of brushes arranged on the commutator. These brushes are mounted on two separate brush rockers, which are designed to move in opposite directions relative to the centre line of the corresponding stator phase (usually by a rack and pinion mechanism). Brushes  $A_1, B_1$ , and  $C_1$  move together and are 120 electrical degrees apart. Similarly, brushes  $A_2, B_2$  and  $C_2$  move together and are also 120 electrical degrees apart. A sectional drawing of the motor is shown in Fig. 35.44.

#### (a) Working

When primary is supplied at line frequency, there is transformer action between primary and regulating winding and normal induction motor action between primary and secondary winding. Hence, voltage at line frequency is induced in the regulating winding by transformer action. The commutator, acting as a frequency changer, converts this line-frequency voltage of the regulating winding to the slip frequency for feeding it into the secondary winding on the stator. The voltage across brush pairs  $A_1A_2, B_1B_2$  and  $C_1C_2$  increases as brushes are separated. In fact, magnitude of the voltage injected into the secondary winding depends on the angle of separation of the brushes  $A_1$  and  $A_2, B_1$  and  $B_2$  and  $C_1$  and  $C_2$ . How slip-frequency e.m.f. is induced in secondary winding is detailed below:

When 3- $\phi$  power is connected to slip-rings, synchronously rotating field is set up in the rotor core. Let us suppose that this field revolves in the clockwise direction. Let us further suppose that brush pairs are on **one commutator segment**, which means that secondary is short-circuited. With rotor still at rest, this field cuts the secondary winding, thereby inducing voltage and so producing currents in it which react with the field to produce **clockwise (CW)** torque in the **stator**. Since stator cannot rotate, as a reaction, it makes the rotor rotate in the **counterclockwise (CCW)** direction.

Suppose that the rotor speed is  $N$  rpm. Then

1. rotor flux is still revolving with synchronous speed relative to the primary and regulating winding.
2. however, this rotor flux will rotate at slip speed  $(N_s - N)$  relative to the stator. It means that the revolving rotor flux will rotate at slip speed in space.
3. if rotor could rotate at synchronous speed *i.e.* if  $N = N_s$ , then flux would be stationary in space (*i.e.* relative to stator) so that there would be no cutting of the secondary winding by the flux and, consequently, no torque would be developed in it.

As seen from above, in a Schrage motor, the flux rotates at synchronous speed, relative to rotor but with slip speed relative to space (*i.e.* stator), whereas in a normal induction motor, flux rotates synchronously relative to stator (*i.e.* space) but with slip speed relative to the rotor. (Art. 34.11).

Another point worth noting is that since at **synchronous** speed, magnetic field is stationary in space, the regulating winding acts as a d.c. armature and the direct current taken from the commutator flows in the secondary winding. Hence, Schrage motor then operates like a synchronous motor.

#### (b) Speed Control

It is quite easy to obtain speeds above as well as below synchronism in a Schrage motor. As shown in Fig. 35.42 (b) (i) when brush pairs are together on the same commutator segment (*i.e.* are electrically connected via commutator), the secondary winding is short-circuited and the machine

Fig. 35.42

operates as an inverted\* plain squirrel-cage induction motor, running with a small positive slip. Parting the brushes in one direction, as shown in Fig. 35.42 (b) (ii) produces subsynchronous speeds, because in this case, regulating voltage injected into the secondary winding *opposes* the voltage induced in it from primary winding. However, when movement of brushes is reversed and they are parted in opposite directions, the direction of the regulating voltage is reversed and so motor speed *increases* to super synchronous (maximum) value, as shown in Fig. 35.41 (b) (iii) The commutator provides maximum voltage when brushes are separated by one pole pitch.

No-load motor speed is given by  $N \cong N_s (1 - K \sin 0.5\beta)$  where  $\beta$  is brush separation in electrical degrees and  $K$  is a constant whose value depends on turn ratio of the secondary and regulating windings.

Maximum and minimum speeds are obtained by changing the magnitude of the regulating voltage. Schrage motors are capable of speed variations from zero to nearly twice the synchronous speed, though a speed range of 3:1 is sufficient for most applications. It is worth noting that Schrage motor is essentially a shunt machine, because for a particular brush separation, speed remains approximately constant as the load torque is increased as happens with dc shunt motors (Art 29.14).

**(c) Power Factor Improvement**

Power factor improvement can be brought about by changing the phase angle of the voltage injected into the secondary winding. As shown in Fig. 35.43, when one set of brushes is advanced more rapidly than the other is retarded, then injected voltage has a quadrature component which leads the rotor induced voltage. Hence, it results in the improvement of motor power factor. This differential movement of brush sets is obtained by coupling the brush rockers to the hand wheel with gears having differing ratios. In Schrage motor, speed depends on angular distance between the individual brush sets ( $A_1$  and  $A_2$  in Fig. 35.41) but p.f. depends on the angular positions of the brushes as a whole.

Fig. 35.43

Fig. 35.44. Sectional drawing of a Schrage motor (Courtesy : Elektra Faurandou, Germany)

**(d) Starting**

Schrage motors are usually started with brushes in the lowest speed position by direct-on contactor starters. Usually, interlocks are provided to prevent the contactor getting closed on the line when brushes are in any other position. One major disadvantage of this motor is that its operating voltage is limited to about 700 V because a.c. power has to be fed through slip-rings. It is available in sizes upto 40 kW and is designed to operate on 220, 440 and 550 V. It is ordinarily wound for four or six poles.

\* Inverted in the sense that primary is in the rotor and secondary in the stator - just opposite of that in the normal induction motor (Art. 34.3).

Fig. 35.44 shows a sectional drawing of a Schrage motor. The details of different parts labelled in the diagram are as under:

1. rotor laminations 2. stator laminations 3. primary winding  
4. secondary winding 5. regulating winding 6. slip-ring unit  
7. commutator 8. cable feed for outer brush yoke 9. cable feed for inner brush yoke 10. hand wheel.

### 35.21. Motor Enclosures

Enclosed and semi-enclosed motors are practically identical with open motors in mechanical construction and in their operating characteristics. Many different types of frames or enclosures are available to suit particular requirements. Some of the common type enclosures are described below:

#### (i) Totally-enclosed, Non-ventilated Type

Such motors have solid frames and end-shields, but no openings for ventilation. They get cooled by surface radiation only (Fig. 35.45). Such surface-cooled motors are seldom furnished in sizes above two or three kW, because higher ratings require frames of much larger sizes than fan-cooled motors of corresponding rating.

**Fig. 35.45.** Totally-enclosed surface cooled 750 W, 750 r.p.m. high torque induction motor (Courtesy : Jyoti Limited)

**Fig. 35.46.** Totally-enclosed, fan-cooled 10-kW 440/400-V, 1000 r.p.m. 50-Hz induction motor (Courtesy : Jyoti Limited)

**Fig. 35.47.** Squirrel-cage motor, showing cowl over the external fan. (Courtesy : General Electric Co. of India)

#### (ii) Splash-proof Type

In the frames of such motors, the ventilating openings are so constructed that the liquid drops or dust particles falling on the motor are coming towards it in a straight line at any angle not greater than  $100^\circ$  from the vertical are not able to enter the motor either directly or by striking and running along the surface.

#### (iii) Totally-enclosed, Fan-cooled Type

In such motors (Fig. 35.46), cooling air is drawn into the motor by a fan mounted on the shaft. This air is forced through the motor between the inner fully-enclosed frame and an outer shell, over the end balls and the stator laminations and is then discharged through openings in the opposite side. An internal fan carries the generated heat to the totally enclosing frame, from where it is conducted to

the outside. Because of totally enclosing frame, all working parts are protected against corrosive or abrasive effects of fumes, dust, and moisture.

**(iv) Cowl-covered Motor**

These motors are simplified form of fan-cooled motors (Fig. 35.47). These consist of totally-enclosed frame with a fan and cowl mounted at the end opposite to the driving end. The air is drawn into the cowl with the help of fan and is then forced over the frame. The contours of the cowl guide the cooling air in proper directions. These motors are superior to the usual fan-cooled motors for operation in extremely dusty atmosphere *i.e.* gas works, chemical works, collieries and quarries etc. because there are no air passages which will become clogged with dust.

Fig. 35.48. Squirrel cage motor

**(v) Protected Type**

This construction consists of perforated covers for the openings in both end shields

Fig. 35.49. Protected slip-ring motor with totally enclosed slip-rings. (Courtesy : General Electric Co. of India)

**(vi) Drip-proof Motors**

The frames of such motors are so constructed that liquid drops or dust particles, falling on the machine at any angle greater than 15° from the vertical, cannot enter the motor, either directly or by striking and running along a horizontal or inwardly inclined smooth surface (Fig. 35.51).

**(vii) Self (Pipe) Ventilated Type**

The construction of such motors consists of enclosed shields with provision for pipe connection on both the shields. The motor fan circulates sufficient air through pipes which are of ample section.

**(viii) Separately (Forced) Ventilated Type**

These motors are similar to the self-ventilated type except that ventilation is provided by a separated blower.

**35.22. Standard Types of Squirrel-cage Motors**

Different types of 3-phase squirrel-cage motors have been standardized, according to their electric characteristics, into six types, designated as design A, B, C, D, E and F respectively. The original commercial squirrel-cage induction motors which were of shallow-slot type are designated as class A. For this reason, Class A motors are used as a reference and are referred to as ‘normal starting-torque, normal starting-current, normal slip’ motors.

**(i) Class A** - Normal starting torque, normal starting current, normal slip

**(ii) Class B** - Normal starting torque, low starting current, normal slip

**(iii) Class C** - High starting torque, low starting current, normal slip

Fig. 35.50. Squirrel cage A C induction motor

(iv) Class *D* - High starting torque, low starting current, high slip

(v) Class *E* - Low starting torque, normal starting current, low slip

(vi) Class *F* - Low starting torque, low starting current, normal slip

### 35.23. Class A Motors

It is the most popular type and employs squirrel cage having relatively low resistance and reactance. Its locked-rotor current with full voltage is generally more than 6 times the rated full-load current. For smaller sizes and number of poles, the starting torque with full voltage is nearly twice the full-load torque whereas for larger sizes and number of poles, the corresponding figure is 1.1 times the full-load torque. The full-load slip is less than 5 per cent. The general configuration of slot construction of such motors is shown in Fig. 35.52. As seen, the rotor bars are placed close to the surface so as to reduce rotor reactance.

Such motors are used for fans, pumps, compressors and conveyors etc. which are started and stopped in frequently and have low inertia loads so that the motor can accelerate in a few seconds.

### 35.24. Class B Motors

These motors are so built that they can be started at full-load while developing normal starting torque with relatively low starting current. Their locked-rotor current with full voltage applied is generally 5 to 5 1/2 times the full-load current. Their cages are of high reactance as seen from Fig. 35.53. The rotor is constructed with deep and narrow bars so as to obtain high reactance during starting.

Such motors are well-suited for those applications where there is limitation on the starting current or if the starting current is still in excess of what can be permitted, then reduced voltage starting is employed. One of the common applications of such motors is large fans most of which have high moment of inertia. It also finds wide use in many machine tool applications, for pumps of centrifugal type and for driving electric generators.

### 35.25. Class C Motors

Such motors are usually of double squirrel-cage type (Fig. 35.54) and combine high starting torque with low starting current. Their locked-rotor currents and slip with full voltage applied are nearly the same as for class *B* motors. Their starting torque with full voltage applied is usually 2.75 times the full-load torque.

For those applications where reduced voltage starting does not give sufficient torque to start the load with either class *A* or *B* motor, class *C* motor, with its high inherent starting torque along with reduced starting current supplied by reduced-voltage starting may be used. Hence, it is frequently used for crushers, compression pumps, large refrigerators, conveyor equipment, textile machinery, boring mills and wood-working equipment etc.

Fig. 35.51. Drip-proof slip-ring 50 up, 440/400-V, 50HZ, 1000 r.p.m. motor (courtesy : Jyoti Limited)

Fig. 35.52

Fig. 35.53

**35.26. Class D Motors**

Such motors are provided with a high-resistance squirrel cage giving the motor a high starting torque with low starting current. Their locked-rotor currents with full voltage applied are of the same order as for class C motors. Their full-load slip varies from 5% to 20 per cent depending on the application. Their slot structure is shown in Fig. 35.55. For obtaining high starting torque with low starting current, thin rotor bars are used which make the leakage flux of the rotor low and the useful flux high.

Since these motors are used where extremely high starting torque is essential, they are usually used for bulldozers, shearing machines, punch presses, foundry equipment, stamping machines, hoists, laundry equipment and metal drawing equipment etc.

Fig. 35.54

Fig. 35.55

**35.27. Class E Motors**

These motors have a relatively low slip at rated load. For motors above 5 kW rating, the starting current may be sufficiently high as to require a compensator or resistance starter. Their slot structure is shown in Fig. 35.56 (a).

Fig. 35.56

**35.28. Class F Motors**

Such motors combine a low starting current with a low starting torque and may be started on full voltage. Their low starting current is due to the design of rotor which has high reactance during starting [Fig. 35.56 (b)]. The locked rotor currents with full voltage applied and the full-load slip are in the same range as those for class B and C motors. The starting torque with full voltage applied is nearly 1.25 times the full-torque.

**QUESTIONS AND ANSWERS ON THREE-PHASE INDUCTION MOTORS**

**Q. 1. How do changes in supply voltage and frequency affect the performance of an induction motor ?**

**Ans.** High voltage decreases both power factor and slip, but increases torque. Low voltage does just the opposite. Increase in frequency increases power factor but decreases the torque. However, per cent slip remains unchanged. Decrease in frequency decreases power factor but increases torque leaving per cent slip unaffected as before.

**Q. 2. What is, in brief, the basis of operation of a 3-phase induction motor ?**

**Ans.** The revolving magnetic field which is produced when a 3-phase stator winding is fed from a 3-phase supply.

**Q. 3. What factors determine the direction of rotation of the motor ?**

**Ans.** The phase sequence of the supply lines and the order in which these lines are connected to the stator winding.

Fig. 35.57

**Q. 4. How can the direction of rotation of the motor be reversed ?**

**Ans.** By transposing or changing over any two line leads, as shown in Fig. 35.57.

**Q. 5. Why are induction motors called asynchronous ?**

**Ans.** Because their rotors can never run with the synchronous speed.

**Q. 6. How does the slip vary with load ?**

**Ans.** The greater the load, greater is the slip or slower is the rotor speed.

**Q. 7. What modifications would be necessary if a motor is required to operate on voltage different from that for which it was originally designed ?**

**Ans.** The number of conductors per slot will have to be changed in the same ratio as the change in voltage. If the voltage is doubled, the number of conductors per slot will have to be doubled.

**Q. 8. Enumerate the possible reasons if a 3-phase motor fails to start.**

**Ans.** Any one of the following reasons could be responsible :

1. one or more fuses may be blown.
2. voltage may be too low.
3. the starting load may be too heavy.
4. worn bearings due to which the armature may be touching field laminae, thus introducing excessive friction.

**Q. 9. A motor stops after starting *i.e.* it fails to carry load. What could be the causes ?**

**Ans.** Any one of the following:

1. hot bearings, which increase the load by excessive friction.
2. excessive tension on belt, which causes the bearings to heat.
3. failure of short cut-out switch.
4. single-phasing on the running position of the starter.

**Q. 10. Which is the usual cause of blow-outs in induction motors ?**

**Ans.** The commonest cause is single-phasing.

**Q. 11. What is meant by 'single-phasing' and what are its causes ?**

**Ans.** By single-phasing is meant the opening of one wire (or leg) of a three-phase circuit whereupon the remaining leg at once becomes single-phase. When a three-phase circuit functions normally, there are three distinct currents flowing in the circuit. As is known, any two of these currents use the third wire as the return path *i.e.* one of the three phases acts as a return path for the other two. Obviously, an open circuit in one leg kills two of the phases and there will be only one current or phase working, even though two wires are left intact. The remaining phase attempts to carry all the load. The usual cause of single-phasing is, what is generally referred to as **running fuse**, which is a fuse whose current-carrying capacity is equal to the full-load current of the motor connected in the circuit. This fuse will blow-out whenever there is overload (either momentary or sustained) on the motor.

**Q. 12. What happens if single-phasing occurs when the motor is running ? And when it is stationary ?**

**Ans.** (i) If already running and carrying half load or less, the motor will continue running as a single-phase motor on the remaining single-phase supply, without damage because half loads do not blow normal fuses.

(ii) If motor is very heavily loaded, then it will stop under single-phasing and since it can neither restart nor blow out the remaining fuses, the burn-out is very prompt.

A stationary motor will not start with one line broken. In fact, due to heavy standstill current, it is likely to burn-out quickly unless immediately disconnected.

**Q. 13. Which phase is likely to burn-out in a single-phasing delta-connected motor, shown in Fig. 35.58.**

**Ans.** The *Y*-phase connected across the live or operative lines carries nearly three times its normal current and is the one most likely to burn-out.

The other two phases *R* and *B*, which are in series across  $L_2$  and  $L_3$  carry more than their full-load currents.

Fig. 35.58

Fig. 35.59

**Q. 14. What currents flow in single-phasing star-connected motor of Fig. 35.59.**

**Ans.** With  $L_1$  disabled, the currents flowing in  $L_2$  and  $L_3$  and through phases  $Y$  and  $B$  in series will be of the order of 250 per cent of the normal full-load current, 160 per cent on 3/4 load and 100 per cent on 1/2 load.

**Q. 15. How can the motors be protected against single-phasing ?**

**Ans.** (i) By incorporating a combined overload and single-phasing relay in the control gear.  
 (ii) By incorporating a phase-failure relay in the control gear. The relay may be either voltage or current-operated.

**Q. 16. Can a 3-phase motor be run on a single-phase line ?**

**Ans.** Yes, it can be. But a phase-splitter is essential.

**Q. 17. What is meant by a phase-splitter ?**

**Ans.** It is a device consisting of a number of capacitors so connected in the motor circuit that it produces, from a single input wave, three output waves which differ in phase from each other.

**Q. 18. What is the standard direction of rotation of an induction motor ?**

**Ans.** Counterclockwise, when looking from the front end *i.e.* non-driving end of the motor.

**Q. 19. Can a wound-motor be reversed by transposing any two leads from the slip-rings ?**

**Ans.** No. There is only one way of doing so *i.e.* by transposing any two line leads.

**Q. 20. What is jogging ?**

**Ans.** It means inching a motor *i.e.* make it move a little at a time by constant starting and stopping.

**Q. 21. What is meant by plugging ?**

**Ans.** It means stopping a motor by instantaneously reversing it till it stops.

**Q. 22. What are the indications of winding faults in an induction motor ?**

**Ans.** Some of the indications are as under:  
 (i) excessive and unbalanced starting currents  
 (ii) some peculiar noises and (iii) overheating.

### OBJECTIVE TESTS – 35

- In the circle diagram for a 3- $\phi$  induction motor, the diameter of the circle is determined by
  - rotor current
  - exciting current
  - total stator current
  - rotor current referred to stator.
- Point out the WRONG statement.  
 Blocked rotor test on a 3- $\phi$  induction motor helps to find
  - short-circuit current with normal voltage
  - short-circuit power factor
  - fixed losses
  - motor resistance as referred to stator.
- In the circle diagram of an induction motor, point of maximum input lies on the tangent drawn parallel to
  - output line
  - torque line
  - vertical axis
  - horizontal axis.

4. An induction motor has a short-circuit current 7 times the full-load current and a full-load slip of 4 per cent. Its line-starting torque is ..... times the full-load torque.  
(a) 7 (b) 1.96  
(c) 4 (d) 49
5. In a SCIM, torque with autostarter is ..... times the torque with direct-switching.  
(a)  $K^2$  (b)  $K$   
(c)  $1/K^2$  (d)  $1/K$   
where  $K$  is the transformation ratio of the autostarter.
6. If stator voltage of a SCIM is reduced to 50 per cent of its rated value, torque developed is reduced by ..... per cent of its full-load value.  
(a) 50 (b) 25  
(c) 75 (d) 57.7
7. For the purpose of starting an induction motor, a Y- $\Delta$  switch is equivalent to an auto-starter of ratio.....per cent.  
(a) 33.3 (b) 57.7  
(c) 73.2 (d) 60.
8. A double squirrel-cage motor (DSCM) scores over SCIM in the matter of  
(a) starting torque  
(b) high efficiency under running conditions  
(c) speed regulation under normal operating conditions  
(d) all of the above.
9. In a DSCM, outer cage is made of high resistance metal bars primarily for the purpose of increasing its  
(a) speed regulation  
(b) starting torque  
(c) efficiency  
(d) starting current.
10. A SCIM with 36-slot stator has two separate windings : one with 3 coil groups/ phase/pole and the other with 2 coil groups/phase/pole. The obtainable two motor speeds would be in the ratio of  
(a) 3 : 2 (b) 2 : 3  
(c) 2 : 1 (d) 1 : 2
11. A 6-pole 3- $\phi$  induction motor taking 25 kW from a 50-Hz supply is cumulatively-cascaded to a 4-pole motor. Neglecting all losses, speed of the 4-pole motor would be ..... r.p.m.  
(a) 1500 (b) 1000  
(c) 600 (d) 3000.  
and its output would be ..... kW.  
(e) 15 (f) 10  
(g) 50/3 (h) 2.5.
12. Which class of induction motor will be well suited for large refrigerators?  
(a) Class E (b) Class B  
(c) Class F (d) Class C
13. In a Schrage motor operating at supersynchronous speed, the injected emf and the standstill secondary induced emf  
(a) are in phase with each other  
(b) are at  $90^\circ$  in time phase with each other  
(c) are in phase opposition  
(d) none of the above.  
**(Power App.-III, Delhi Univ. July 1987)**
14. For starting a Schrage motor, 3- $\phi$  supply is connected to  
(a) stator  
(b) rotor via slip-rings  
(c) regulating winding  
(d) secondary winding via brushes.
15. Two separate induction motors, having 6 poles and 5 poles respectively and their cascade combination from 60 Hz, 3-phase supply can give the following synchronous speeds in rpm  
(a) 720, 1200, 1500 and 3600  
(b) 720, 1200 1800  
(c) 600, 1000, 15000  
(d) 720 and 3000  
**(Power App.-II, Delhi Univ. Jan 1987)**
16. Mark the WRONG statement.  
A Schrage motor is capable of behaving as a/an  
(a) inverted induction motor  
(b) slip-ring induction motor  
(c) shunt motor  
(d) series motor  
(e) synchronous motor.
17. When a stationary 3-phase induction motor is switched on with one phase disconnected  
(a) it is likely to burn out quickly unless immediately disconnected  
(b) it will start but very slowly  
(c) it will make jerky start with loud growing noise  
(d) remaining intact fuses will be blown out due to heavy inrush of current
18. If single-phasing of a 3-phase induction motor occurs under running conditions, it  
(a) will stall immediately  
(b) will keep running though with slightly increased slip  
(c) may either stall or keep running depending on the load carried by it  
(d) will become noisy while it still keeps running.

## SINGLE-PHASE MOTORS

↑ Single phase motor

### 36.1. Types of Single-Phase Motors

Such motors, which are designed to operate from a single-phase supply, are manufactured in a large number of types to perform a wide variety of useful services in home, offices, factories, workshops and in business establishments etc. Small motors, particularly in the fractional kilo watt sizes are better known than any other. In fact, most of the new products of the manufacturers of space vehicles, aircrafts, business machines and power tools etc. have been possible due to the advances made in the design of fractional-kilowatt motors. Since the performance requirements of the various applications differ so widely, the motor-manufacturing industry has developed many different types of such motors, each being designed to meet specific demands.

Split-phase motor. Switch mechanism disconnects start winding when motor reached three-fourths of rated speed

Single-phase motors may be classified as under, depending on their construction and method of starting :

1. **Induction Motors** (split-phase, capacitor and shaded-pole etc.)
2. **Repulsion Motors** (sometime called Inductive-Series Motors)
3. **A.C. Series Motor**
4. **Un-excited Synchronous Motors**

### 36.2. Single-phase Induction Motor

Constructionally, this motor is, more or less, similar to a polyphase induction motor, except that (i) its stator is provided with a single-phase winding and (ii) a centrifugal switch is used in some types of motors, in order to cut out a winding, used only for starting purposes. It has distributed stator winding and a squirrel-cage rotor. When fed from a single-phase supply, its stator winding produces a flux (or field) which is only *alternating i.e.* one which alternates along one space axis only. It is not a synchronously revolving (or rotating) flux, as in the case of a two- or a three-phase stator winding, fed from a 2- or 3-phase supply. Now, an alternating or pulsating flux acting on a *stationary* squirrel-cage rotor cannot produce rotation (only a revolving flux can). That is why a single-phase motor is *not self-starting*.

Single-phase induction motor

However, if the rotor of such a machine is given an initial start by hand (or small motor) or otherwise, *in either* direction, then immediately a torque arises and the motor accelerates to its final speed (unless the applied torque is too high).

This peculiar behaviour of the motor has been explained in two ways : (i) by two -field or double-field revolving theory and (ii) by cross-field theory. Only the first theory will be discussed briefly.

### 36.3. Double-field Revolving Theory

This theory makes use of the idea that an alternating uni-axial quantity can be represented by two oppositely-rotating vectors of half magnitude. Accordingly, an *alternating* sinusoidal flux can be

represented by two **revolving** fluxes, each equal to half the value of the alternating flux and each rotating synchronously ( $N_s = 120f/P$ ) in opposite direction\*.

As shown in Fig. 36.1 (a), let the alternating flux have a maximum value of  $\Phi_m$ . Its component fluxes A and B will each be equal to  $\Phi_m/2$  revolving in anticlockwise and clockwise directions respectively.

Fig. 36.1

After some time, when A and B would have rotated through angle  $+\theta$  and  $-\theta$ , as in Fig. 36.1 (b), the resultant flux would be

$$= 2 \times \frac{\Phi_m}{2} \cos \frac{2\theta}{2} = \Phi_m \cos \theta$$

After a quarter cycle of rotation, fluxes A and B will be oppositely-directed as shown in Fig. 36.1 (c) so that the resultant flux would be zero.

After half a cycle, fluxes A and B will have a resultant of  $-2 \times \Phi_m/2 = -\Phi_m$ . After three-quarters of a cycle, again the resultant is

Fig. 36.2

\* For example, a flux given by  $\Phi = \Phi_m \cos 2\pi ft$  is equivalent to two fluxes revolving in opposite directions, each with a magnitude of  $1/2\Phi$  and an angular velocity of  $2\pi f$ . It may be noted that Euler's expressions for  $\cos \theta$  provides interesting justification for the decomposition of a pulsating flux. His expression is

$$\cos \theta = \frac{e^{j\theta} + e^{-j\theta}}{2}$$

The term  $e^{j\theta}$  represents a vector rotated clockwise through an angle  $\theta$  whereas  $e^{-j\theta}$  represents rotation in anticlockwise direction. Now, the above given flux can be expressed as

$$\Phi_m \cos 2\pi ft = \frac{\Phi_m}{2} (e^{j2\pi ft} + e^{-j2\pi ft})$$

The right-hand expression represents two oppositely-rotating vectors of half magnitude.

zero, as shown in Fig. 36.1 (e) and so on. If we plot the values of resultant flux against  $\theta$  between limits  $\theta = 0^\circ$  to  $\theta = 360^\circ$ , then a curve similar to the one shown in Fig. 36.2 is obtained. That is why an alternating flux can be looked upon as composed of two revolving fluxes, each of half the value and revolving synchronously in opposite directions.

It may be noted that if the slip of the rotor is  $s$  with respect to the forward rotating flux (*i.e.* one which rotates in the same direction as rotor) then its slip with respect to the backward rotating flux is  $(2 - s)^*$ .

Each of the two component fluxes, while revolving round the stator, cuts the rotor, induces an e.m.f. and this produces its own torque. Obviously, the two torques (called forward and backward torques) are oppositely-directed, so that the net or resultant torque is equal to their difference as shown in Fig. 36.3.

Now, power developed by a rotor is  $P_g = \left(\frac{1-s}{s}\right) I_2^2 R_2$

If  $N$  is the rotor r.p.s., then torque is given by  $T_g = \frac{1}{2\pi N} \cdot \left(\frac{1-s}{s}\right) I_2^2 R_2$

Now,  $N = N_s(1-s) \quad \therefore T_g = \frac{1}{2\pi N_s} \cdot \frac{I_2^2 R_2}{s} = k \cdot \frac{I_2^2 R_2}{s}$

Hence, the forward and backward torques are given by

$$T_f = K \frac{I_2^2 R_2}{s} \quad \text{and} \quad T_b = -K \cdot \frac{I_2^2 R_2}{(2-s)}$$

or  $T_f = \frac{I_2^2 R_2}{s}$  synch.watt and  $T_b = -\frac{I_2^2 R_2}{(2-s)}$  synch. watt

Total torque  $T = T_f + T_b$

Fig. 36.3 shows both torques and the resultant torque for slips between zero and +2. At standstill,  $s = 1$  and  $(2 - s) = 1$ . Hence,  $T_f$  and  $T_b$  are numerically equal but, being oppositely directed, produce no resultant torque. That explains why there is no **start-ing** torque in a single-phase induction motor.

However, if the rotor is started somehow, say, in the clockwise direction, the clockwise torque starts increasing and, at the same time, the anticlockwise torque starts decreasing. Hence, there is a certain amount of net torque in the clockwise direction which accelerates the motor to full speed.

Fig. 36.3

\* It may be proved thus : If  $N$  is the r.p.m. of the rotor, then its slip with respect to forward rotating flux is

$$s = \frac{N_s - N}{N_s} = 1 - \frac{N}{N_s} \quad \text{or} \quad \frac{N}{N_s} = 1 - s$$

Keeping in mind the fact that the backward rotating flux rotates opposite to the rotor, the rotor slip with respect to this flux is

$$s_b = \frac{N_s - (-N)}{N_s} = 1 + \frac{N}{N_s} = 1 + (1 - s) = (2 - s)$$

### 36.4. Making Single-phase Induction Motor Self-starting

As discussed above, a single-phase induction motor is not self-starting. To overcome this drawback and make the motor self-starting, it is temporarily converted into a two-phase motor during starting period. For this purpose, the stator of a single-phase motor is provided with an extra winding, known as **starting** (or auxiliary) winding, in addition to the **main or running winding**. The two windings are spaced  $90^\circ$  electrically apart and are connected in *parallel* across the single-phase supply as shown in Fig. 36.4.

Fig. 36.4

It is so arranged that the phase-difference between the currents in the two stator windings is very large (ideal value being  $90^\circ$ ). Hence, the motor behaves like a two-phase motor. These two currents produce a revolving flux and hence make the motor self-starting.

There are many methods by which the necessary phase-difference between the two currents can be created.

(i) In *split-phase machine*, shown in Fig. 36.5 (a), the main winding has low resistance but high reactance whereas the starting winding has a high resistance, but low reactance. The resistance of the starting winding may be increased either by connecting a high resistance  $R$  in series with it or by choosing a high-resistance fine copper wire for winding purposes.

Single-phase motor.

Hence, as shown in Fig. 36.5 (b), the current  $I_s$  drawn by the starting winding lags behind the applied voltage  $V$  by a small angle whereas current  $I_m$  taken by the main winding lags behind  $V$  by a very large angle. Phase angle between  $I_s$  and  $I_m$  is made as large as possible because the starting torque of a split-phase motor is proportional to  $\sin \alpha$ . A centrifugal switch  $S$  is connected in series with the starting winding and is located inside the motor. Its function is to automatically disconnect the starting winding from the supply when the motor has reached 70 to 80 per cent of its full-load speed.

In the case of split-phase motors that are hermetically sealed in refrigeration units, instead of internally-mounted centrifugal switch, an electromagnetic type of relay is used. As shown in Fig. 36.6, the relay coil is connected in series with main winding and the pair of contacts which are normally open, is included in the starting winding.

Fig. 36.5

Fig. 36.6

During starting period, when  $I_m$  is large, relay contacts close thereby allowing  $I_s$  to flow and the motor starts as usual. After motor speeds up to 75 per cent of full-load speed,  $I_m$  drops to a value that is low enough to cause the contacts to open.

A typical torque/speed characteristic of such a motor is shown in Fig. 36.7. As seen, the starting torque is 150 to 200 per cent of the full-load torque with a starting current of 6 to 8 times the full-load current. These motors are often used in preference to the costlier capacitor-start motors. Typical applications are : fans and blowers, centrifugal pumps and separators, washing machines, small machine tools, duplicating machines and domestic refrigerators and oil burners etc. Commonly available sizes range from 1/20 to 1/3 h.p. (40 to 250 W) with speeds ranging from 3,450 to 865 r.p.m.

As shown in Fig. 36.8, the direction of rotation of such motors can be reversed by reversing the connections of one of the two stator windings (not both). For this purpose, the four leads are brought outside the frame.

As seen from Fig. 36.9, the connections of the starting winding have been reversed.

Fig. 36.7

Fig. 36.8

Fig. 36.9

The speed regulation of standard split-phase motors is nearly the same as of the 3-phase motors. Their speed varies about 2 to 5% between no load and full-load. For this reason such motors are usually regarded as practically constant-speed motors.

**Note.** Such motors are sometimes referred to as resistance-start split-phase induction motors in order to distinguish them from capacitor-start induction run and capacitor start-and-run motors described later.

Fig. 36.10

Fig. 36.11

Fig. 36.12

**(ii) Capacitor-start Induction-run motors.** In these motors, the necessary phase difference between  $I_s$  and  $I_m$  is produced by connecting a capacitor in series with the starting winding as shown in Fig. 36.10. The capacitor is generally of the electrolytic type and is usually mounted on the outside of the motor as a separate unit (Fig. 36.11).

The capacitor is designed for extremely short-duty service and is guaranteed for not more than 20 periods of operation per hour, each period not to exceed 3 seconds. When the motor reaches about

75 per cent of full speed, the centrifugal switch  $S$  opens and cuts out both the starting winding and the capacitor from the supply, thus leaving only the running winding across the lines. As shown in Fig.

Capacitor start/capacitor-run motor.

36.12, current  $I_m$  drawn by the main winding lags the supply voltage  $V$  by a large angle whereas  $I_s$  leads  $V$  by a certain angle. The two currents are out of phase with each other by about  $80^\circ$  (for a 200-W 50-Hz motor) as compared to nearly  $30^\circ$  for a split-phase motor. Their resultant current  $I$  is small and is almost in phase with  $V$  as shown in Fig. 36.12.

Since the torque developed by a split-phase motor is proportional to the sine of the angle between  $I_s$  and  $I_m$ , it is obvious that the

increase in the angle (from  $30^\circ$  to  $80^\circ$ ) alone increases the starting torque to nearly twice the value developed by a standard split-phase induction motor. Other improvements in motor design have made it possible to increase the starting torque to a value as high as 350 to 450 per cent.

Typical performance curve of such a motor is shown in Fig. 36.13.

Fig. 36.13

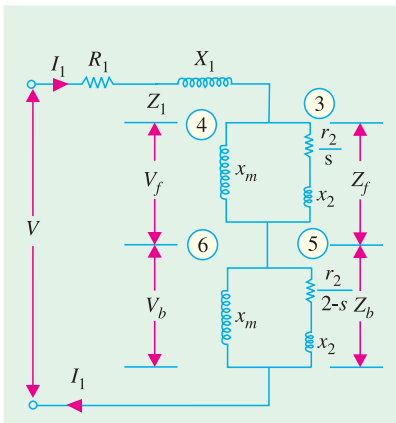

Fig. 36.14

### 36.5. Equivalent Circuit of a Single-phase Induction Motor-Without Core Loss

A single-phase motor may be looked upon as consisting of two motors, having a common stator winding, but with their respective rotors revolving in opposite directions. The equivalent circuit of such a motor based on double-field revolving theory is shown in Fig. 36.14. Here, the single-phase motor has been imagined to be made-up of (i) one stator winding and (ii) two imaginary rotors. The stator impedance is  $Z = R_1 + j X_1$ . The impedance of each rotor is  $(r_2 + jx_2)$  where  $r_2$  and  $x_2$  represent half the actual rotor values in stator terms (i.e.  $x_2$  stands for half the standstill reactance of the rotor, as referred to stator). Since iron loss has been neglected, the exciting branch is shown consisting of exciting reactance only. Each rotor has been assigned half the magnetising reactance\* (i.e.  $x_m$  represents half the actual reactance). The

impedance of 'forward running' rotor is

$$Z_f = \frac{j x_m \left( \frac{r_2}{s} + j x_2 \right)}{\frac{r_2}{s} + j (x_m + x_2)}$$

and it runs with a slip of  $s$ . The impedance of 'backward' running rotor is

\* In fact, full values are shown by capital letters and half values by small letters.

$$Z_b = \frac{j x_m \left( \frac{r_2}{2-s} + j x_2 \right)}{\frac{r_2}{2-s} + j (x_m + x_2)}$$

and it runs with a slip of  $(2 - s)$ . Under standstill conditions,  $V_f = V_b$ , but under running conditions  $V_f$  is almost 90 to 95% of the applied voltage.

The forward torque in synchronous watts is  $T_f = I_3^2 r_2 / s$ . Similarly, backward torque is  $T_b = I_5^2 r_2 / (2 - s)$

The total torque is  $T = T_f - T_b$ .

### 36.6. Equivalent Circuit-With Core Loss

The core loss can be represented by an equivalent resistance which may be connected either in parallel or in series with the magnetising reactance as shown in Fig. 36.15.

Since under running conditions  $V_f$  is very high (and  $V_b$  is correspondingly, low) most of the iron loss takes place in the ‘forward motor’ consisting of the common stator and forward-running rotor. Core-loss current  $I_w = \text{core loss} / V_f$ . Hence, half value of core-loss equivalent resistance is  $r_c = V_f / I_w$ . As shown in Fig. 36.15 (a),  $r_c$  has been connected in parallel with  $x_m$  in each rotor.

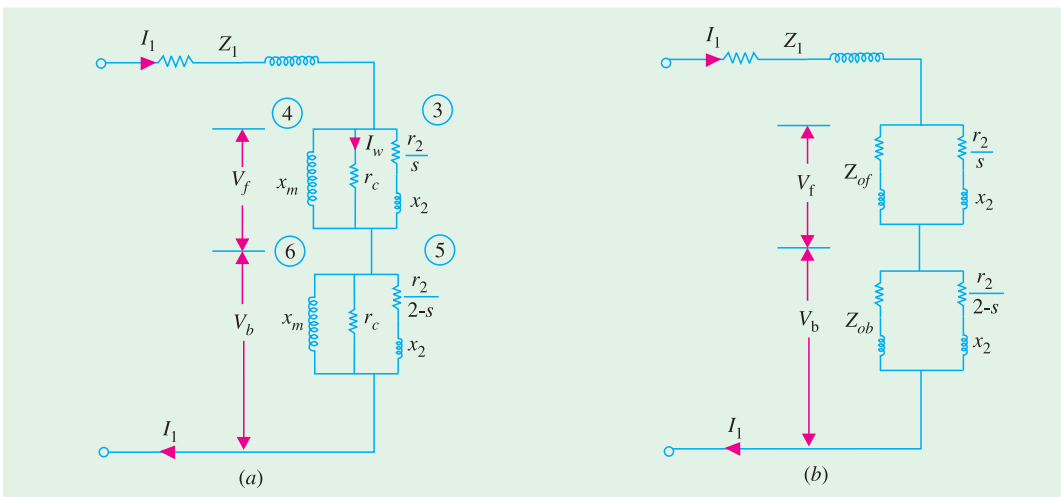

Fig. 36.15

**Example 36.1.** Discuss the revolving field theory of single-phase induction motors. Find the mechanical power output at a slip of 0.05 of the 185-W, 4-pole, 110-V, 60-Hz single-phase induction motor, whose constants are given below:

Resistance of the stator main winding	$R_1 = 1.86 \text{ ohm}$
Reactance of the stator main winding	$X_1 = 2.56 \text{ ohm}$
Magnetizing reactance of the stator main winding	$X_m = 53.5 \text{ ohm}$
Rotor resistance at standstill	$R_2 = 3.56 \text{ ohm}$
Rotor reactance at standstill	$X_2 = 2.56 \text{ ohm}$

(Elect. Machines, Nagpur Univ. 1991)

**Solution.** Here,  $X_m = 53.5 \Omega$ , hence  $x_m = 53.5/2 = 26.7 \Omega$

Similarly,  $r_2 = R_2 / 2 = 3.56 / 2 = 1.78 \Omega$  and  $x_2 = X_2 / 2 = 2.56 / 2 = 1.28 \Omega$

$$\therefore Z_f = \frac{j x_m \left( \frac{r_2}{s} + j x_2 \right)}{\frac{r_2}{s} + j (x_2 + x_m)} = x_m \frac{\frac{r_2}{s} \cdot x_m + j \left[ (r_2/s)^2 + x_2 x_0 \right]}{(r_2/s)^2 + x_0^2} \quad \text{where } x_0 = (x_m + x_2)$$

$$\therefore Z_f = 26.7 \frac{(1.78/0.05) \times 26.7 + j [(1.78/0.05)^2 + 1.28 \times 27.98]}{(1.78/0.05)^2 + (27.98)^2}$$

$$= 12.4 + j 17.15 = 21.15 \angle 54.2^\circ$$

Similarly,  $Z_b = \frac{j x_m \left( \frac{r_2}{2-s} + j x_2 \right)}{\frac{r_2}{2-s} + j (x_2 + x_m)} = x_m \frac{\left( \frac{r_2}{2-s} \right) x_m + j \left[ \left( \frac{r_2}{2-s} \right)^2 + x_0 x_2 \right]}{\left( \frac{r_2}{2-s} \right)^2 + x_0^2}$

$$= 26.7 \frac{(1.78/1.95) \times 26.7 + j [(1.78/1.95)^2 + 1.28 \times 27.98]}{(1.78/1.95)^2 + (27.98)^2}$$

$$= 0.84 + j 1.26 = 1.51 \angle 56.3^\circ$$

$$\mathbf{Z_1} = R_1 + j X_1 = 1.86 + j 2.56 = 3.16 \angle 54^\circ$$

Total circuit impedance is

$$\mathbf{Z_{01}} = \mathbf{Z_1} + \mathbf{Z_f} + \mathbf{Z_b} = (1.86 + j 2.56) + (12.4 + j 17.15) + (0.84 + j 1.26)$$

$$= 15.1 + j 20.97 = 25.85 \angle 54.3^\circ$$

Motor current  $I_1 = 110/25.85 = 4.27 \text{ A}$

$$V_f = I_1 Z_f = 4.27 \times 21.15 = 90.4 \text{ V}; V_b = I_1 Z_b = 4.27 \times 1.51 = 6.44 \text{ V}$$

$$Z_3 = \sqrt{\left( \frac{r_2}{s} \right)^2 + x_2^2} = 35.7 \Omega, Z_5 = \sqrt{\left( \frac{r_2}{2-s} \right)^2 + x_2^2} = 1.57 \Omega$$

$$I_3 = V_f / Z_3 = 90.4/35.7 = 2.53 \text{ A}, I_5 = V_b / Z_5 = 6.44/1.57 = 4.1 \text{ A}$$

$$T_f = I_3^2 R_2 / s = 228 \text{ synch. watts}, T_5 = I_5^2 r_2 / (2-s) = 15.3 \text{ synch. watts.}$$

$$T = T_f - T_b = 228 - 15.3 = 212.7 \text{ synch. watts}$$

$$\text{Output} = \text{synch. watt} \times (1-s) = 212.7 \times 0.95 = \mathbf{202 \text{ W}}$$

Since friction and windage losses are not given, this also represents the net output.

**Example 36.2.** Find the mechanical power output of 185-W, 4 pole, 110-V, 50-Hz single-phase induction motor, whose constants are given below at a slip of 0.05.

$$R_1 = 1.86 \Omega \quad X_1 = 2.56 \Omega \quad X_\phi = 53.5 \Omega \quad R_2 = 3.56 \Omega \quad X_2 = 2.56 \Omega$$

$$\text{Core loss} = 3.5 \text{ W, Friction and windage loss} = 13.5 \text{ W.}$$

(Electrical Machines-III, Indore Univ. 1987)

**Solution.** It would be seen that major part of this problem has already been solved in Example 36.1. Let us, now, assume that  $V_f = 82.5\%$  of 110 V = 90.7 V. Then the core-loss current  $I_c = 35/90.7 = 0.386 \text{ A}$ ;  $r_c = 90.7/0.386 = 235 \Omega$ .

#### Motor I

$$\text{conductance of core-loss branch} = 1/r_c = 1/235 = 0.00426 \text{ S}$$

$$\text{susceptance of magnetising branch} = -j/x_m = -j/26.7 = -j 0.0374 \text{ S}$$

$$\text{admittance of branch 3} = \frac{(r_2/s) - j x_2}{(r_2/s)^2 + x_2^2} = 0.028 - j 0.00101 \text{ S}$$

admittance of 'motor' I is  $Y_f = 0.00426 - j 0.0374 + 0.028 - j 0.00101$   
 $= 0.03226 - j 0.03841 \text{ S}$

impedance  $Z_f = 1/Y_f = 12.96 + j 15.2 \text{ or } 19.9 \Omega$

**Motor II**

admittance of branch 5  $= \frac{\frac{r_2}{2-s} - j x_2}{\left(\frac{r_2}{2-s}\right)^2 + x_2^2} = \frac{0.91 - j 1.28}{2.469} = 0.369 - j 0.517$

admittance of 'motor' II,  $Y_b = 0.00426 - j 0.0374 + 0.369 - j 0.517$   
 $= 0.3733 - j 0.555 \text{ S}$

Impedance of 'motor' II,  $Z_b = 1/Y_b = 0.836 + j 1.242 \text{ or } 1.5 \Omega$

Impedance of entire motor (Fig. 36.16)  $Z_{01} = Z_1 + Z_f + Z_b = 15.66 + j 19 \text{ or } 24.7 \Omega$

$I_1 = V/Z_{01} = 110/24.7 = 4.46 \text{ A}$

$V_f = I_1 Z_f = 4.46 \times 19.9 = 88.8 \text{ V}$

$V_b = 4.46 \times 1.5 = 6.69 \text{ V}$

$I_3 = 88.8/35.62 = 2.5 \text{ A}$

$I_5 = 6.69/1.57 = 4.25 \text{ A}$

$T_f = I_3^2 (r_2/s) = 222 \text{ synch. watt}$

$T_b = I_5^2 \left(\frac{r_2}{2-s}\right) = 16.5 \text{ synch. watt}$

$T = T_f - T_b = 205.5 \text{ synch. watt}$

Watts converted = synch. watt (1 - s)  
 $= 205.5 \times 0.95 = 195 \text{ W}$

Net output =  $195 - 13.5 = 181.5 \text{ W}$ .

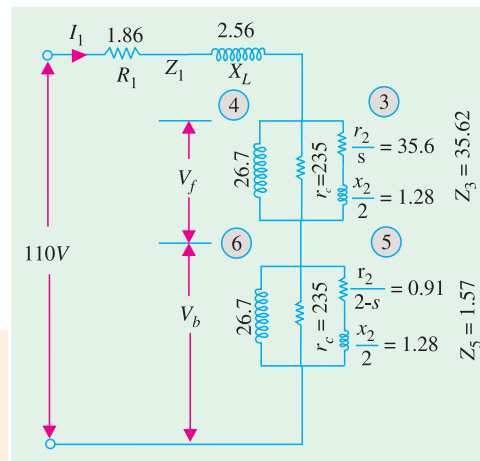

Fig. 36.16

**Example 36.3.** A 250-W, 230-V, 50-Hz capacitor-start motor has the following constants for the main and auxiliary windings: Main winding,  $Z_m = (4.5 + j 3.7) \text{ ohm}$ . Auxiliary winding  $Z_a = (9.5 + j 3.5) \text{ ohm}$ . Determine the value of the starting capacitor that will place the main and auxiliary winding currents in quadrature at starting.

(Electrical Machines-III, South Gujarat Univ. 1985)

**Solution.** Let  $X_C$  be the reactance of the capacitor connected in the auxiliary winding.

Then  $Z_a = 9.5 + j 3.5 - j X_C = (9.5 + jX)$   
 where  $X$  is the net reactance.

Now,  $Z_m = 4.5 + j 3.5 = 5.82 \angle 39.4^\circ \text{ ohm}$

Obviously,  $I_m$  lags behind  $V$  by  $39.4^\circ$

Since, time phase angle between  $I_m$  and  $I_a$  has to be  $90^\circ$ ,  $I_a$  must lead  $V$  by

$(90^\circ - 39.4^\circ) = 50.6^\circ$ .

For auxiliary winding,  $\tan \phi_a = X/R$  or  $\tan 50.6^\circ = X/9.5$

or  $X = 9.5 \times 1.217 = 11.56 \Omega$  (capacitive)

$\therefore X_C = 11.56 + 3.5 = 15.06 \Omega \quad \therefore 15.06 = 1/314 C; C = 211 \mu\text{F}$

### Tutorial Problem No. 36.1.

1. A 1- $\phi$ , induction motor has stator windings in space quadrature and is supplied with a single-phase voltage of 200 V at 50 Hz. The standstill impedance of the main winding is  $(5.2 + j 10.1)$  and of the auxiliary winding is  $(19.7 + j 14.2)$ . Find the value of capacitance to be inserted in the auxiliary winding for maximum starting torque. *(Electrical Machines-III, Indore Univ. July, 1977)*

2. A 230-V, 50-Hz, 6-pole, single-phase induction motor has the following constants.

$$r_1 = 0.12 \Omega, r_2 = 0.14 \Omega, x_1 = x_2 = 0.25 \Omega, x_m = 15 \Omega.$$

If the core loss is 250 W and friction and windage losses are 500 W, determine the efficiency and torque at  $s = 0.05$ . *(Electrical Machines-IV, Bangalore Univ. Aug. 1978)*

3. Explain how the pulsating mmf of a single-phase induction motor may be considered equivalent to two oppositely-rotating fields. Develop an expression for the torque of the motor.

A 125-W, 4-pole, 110-V, 50-Hz single-phase induction motor has the no-load rotational loss of 25 watts and total rotor copper loss at rated load of 25 watts at a slip of 0.06. The rotor  $I^2R$  loss may be neglected.

At a slip  $s = 0.06$ , what is the power input to the machine ?

*(Electrical Machines-III, Indore Univ. July 1977)*

### 36.7. Types of Capacitor-start Motors

Some of the important types of such motors are given below :

#### 1. Single-voltage, externally-reversible type

In this motor, four leads are brought outside its housing; two from the main winding and two from the starting-winding circuit. These four leads are necessary for external reversing. As usual, internally, the starting winding is connected in series with the electrolytic capacitor and a centrifugal switch. The direction of rotation of the motor can be easily reversed externally by reversing the starting winding leads with respect to the running winding leads.

#### 2. Single-voltage, non-reversible type

In this case, the starting winding leads are connected internally to the leads of the running winding. Consequently, there are only two external leads in such motors. Obviously, direction of rotation cannot be reversed unless the motor is taken apart and leads of the starting winding reversed.

#### 3. Single-voltage reversible and with thermostat type

Many motors are fitted with a device called thermostat which provides protection against overload, overheating, and short-circuits etc. The thermostat usually consists of a bimetallic element that is connected in series with the motor and is often mounted on the outside of the motor.

The wiring diagram of a capacitor-start motor fitted with this protective device is shown in Fig. 36.17. When due to some reasons, excessive current flows through the motor, it produces abnormal heating of the bimetallic strip with the result that it bends and opens the contact points thus disconnecting the motor from the supply lines. When the thermostat element cools, it automatically closes the contacts\*.

In the case of capacitor-start motors used for refrigerators, generally a terminal block is attached to the motor. Three out of the four block terminals are marked  $T$ ,  $TL$  and  $L$  as shown in Fig. 36.18. Thermostat is connected to  $T$  and  $TL$ , capacitor between  $L$  and the unmarked terminal and the supply lines to  $TL$  and  $L$ .

---

\* However, in some thermal units, a reset button has to be operated manually to restore the motor to operation. In certain types of thermal units, a heating element is used for heating the bimetallic strip. In that case, the heating element is connected in the line and the element or bimetallic strip is placed either inside the heating unit or besides it.

**4. Single-voltage, non-reversible with magnetic switch type**

Such motors are commonly used in refrigerators where it is not possible to use a centrifugal switch. The circuit diagram is similar to that shown in Fig. 36.6. Since their application requires just one direction of rotation, these motors are not connected for reversing.

Fig. 36.17

Fig. 36.18

One disadvantage of a capacitor-start motor having magnetic switch lies in the possibility that slight overloads may operate the plunger thereby connecting the starting winding circuit to the supply. Since this winding is designed to operate for very short periods (3 seconds or less) it is likely to be burnt out.

**5. Two-voltage, non-reversible Type**

These motors can be operated from two a.c. voltage either 110 V and 220 V or 220 V and 440 V. Such motors have two main windings (or one main winding in two sections) and one starting winding with suitable number of leads brought out to permit changeover from one voltage to another.

Fig. 36.19

Fig. 36.20

When the motor is to operate from lower voltage, the two main windings are connected in parallel (Fig. 36.19). Whereas for higher voltage, they are connected in series (Fig. 36.20). As will be seen from the above circuit diagrams, the starting winding is always operated on the low-voltage for which purpose it is connected across one of the main windings.

**6. Two-voltage, reversible type**

External reversing is made possible by means of two additional leads that are brought out from the starting winding.

Fig. 36.21 and 36.22 show connections for clockwise and anticlockwise rotations respectively when motor is operated from lower voltage. Similar wiring diagram can be drawn for higher voltage supply.

**7. Single-voltage, three-lead reversible type**

In such motors, a two-section running winding is used. The two sections  $R_1$  and  $R_2$  are internally connected in series and one lead of the starting winding is connected to the mid-point of  $R_1$  and  $R_2$ .

Fig. 36.21

Fig. 36.22

Fig. 36.23

The second lead of the starting winding and both leads of the running winding are brought outside as shown in Fig. 36.23. When the external lead of the starting winding is connected to point A, the winding is connected across  $R_1$  and the motor runs clockwise. When the lead of starter winding is connected to point B, it is connected across  $R_2$ . Since current flowing through starting winding is reversed, the motor runs in counter-clockwise direction.

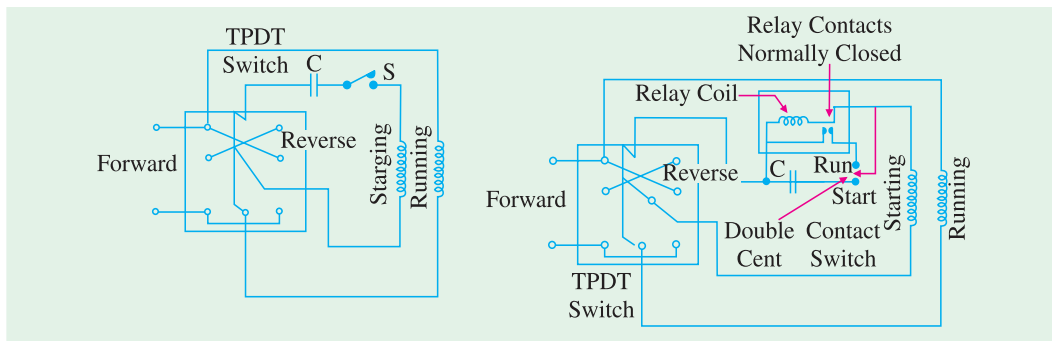

Fig. 36.24

Fig. 36.25

**8. Single-voltage, instantly-reversible type**

Normally, a motor must be brought to complete rest before it can be started in the reverse direction. It is so because the centrifugal switch cannot close unless the motor has practically stopped. Since starting winding is disconnected from supply when the motor is running, reversal of starting winding leads will not affect the operation of the motor. This reversal is achieved by a triple-pole, double-throw (TPDT) switch as shown in Fig. 36.24. The switch consists of three blades or poles which move together as one unit in either of the two positions. In one position of the switch (shown in one figure) motor runs clockwise and in the other, in counter-clockwise direction. Obviously, in this type of arrangement, it is necessary to wait till motor stops.

In certain applications where instant reversal is necessary while the motor is operating at full speed, a relay is fitted in the circuit to short-circuit the centrifugal switch and connect the starting winding in the circuit in the reversed direction (Fig. 36.25).

It will be seen that when at rest, the double-contact centrifugal switch is in the 'start' position. In this position, two connections are made :

- (i) the starting winding and capacitor  $C$  are placed in series across the supply line and
- (ii) the coil of the normally-closed relay is connected across  $C$

With the manual *TPDT* switch in the ‘forward’ position (a) running winding is connected across the line (b) starting winding and  $C$  are in series across the line and (c) relay coil is connected across  $C$ . The voltage developed across  $C$  is applied across the relay coil which results in opening of the relay contacts. With increase in the speed of the motor, the centrifugal switch is thrown in the ‘running’ position. This cuts out  $C$  from the circuit and leaves starting winding in series with the relay coil. Since relay coil has high resistance, it permits only enough current through the starting winding as to keep the relay contacts open.

During the fraction-of-a-second interval while *TPDT* switch is shifted from ‘forward’ to ‘reverse’ position, no current flows through the relay coil as a result of which the relay contacts close. When *TPDT* switch reaches the ‘reverse’ position, current flows through the now-closed relay contacts to the starting winding but in opposite direction. This produces a torque which is applied in a direction opposite to the rotation. Hence, (i) rotor is immediately brought to rest and (ii) centrifugal switch falls to the ‘start’ position. As before,  $C$  is put in series with the starter winding and the motor starts rotating in the opposite direction.

**9. Two-speed type**

Speed can be changed by changing the number of poles in the winding for which purpose two separate running windings are placed in the slots of the stator, one being 6-pole winding and the other, 8-pole winding. Only one starting winding is used which always acts in conjunction with the higher-speed running winding. The double-action or transfer type centrifugal switch  $S$  has two contact

Fig. 36.26

Fig. 36.27

points on the ‘start’ side and one on the ‘run’ side. As shown in Fig. 36.26, an external speed switch is used for changing the motor speed. The motor will always start on high speed irrespective of whether the speed switch is on the ‘high’ or ‘low’ contact. If speed switch is set on ‘low’, then as soon as the motor comes up to speed, the centrifugal switch

- (a) cuts out the starting winding and high-speed running winding and
- (b) cuts in the low-speed running winding.

**10. Two-speed with two-capacitor type**

As shown in Fig. 36.27, this motor has two running windings, two starting windings and two capacitors. One capacitor is used for high-speed operation and the other for low-speed operation. A double centrifugal switch  $S$  is employed for cutting out the starting winding after start.

### 36.8. Capacitor Start-and-Run Motor

This motor is similar to the capacitor-start motor [Art.36.4 (ii)] except that the starting winding and capacitor are connected in the circuit at **all times**. The advantages of leaving the capacitor permanently in circuit are (i) improvement of over-load capacity of the motor (ii) a higher power factor (iii) higher efficiency and (iv) quieter running of the motor which is so much desirable for small power drives in offices and laboratories. Some of these motors which start and run with one value of capacitance in the circuit are called **single-value** capacitor-run motors. Other which start with high value of capacitance but run with a low value of capacitance are known as **two-value** capacitor-run motors.

Capacitor starts and run motor

#### (i) Single-value capacitor-Run Motor

It has one running winding and one starting winding in series with a capacitor as shown in Fig. 36.28. Since capacitor remains in the circuit permanently, this motor is often referred to as permanent-

Fig. 36.28

Fig. 36.29

Fig. 36.30

split capacitor-run motor and behaves practically like an unbalanced 2-phase motor. Obviously, there is no need to use a centrifugal switch which was necessary in the case of capacitor-start motors. Since the same capacitor is used for starting and running, it is obvious that neither optimum starting nor optimum running performance can be obtained because value of capacitance used must be a compromise between the best value for starting and that for running. Generally, capacitors of 2 to 20  $\mu\text{F}$  capacitance are employed and are more expensive oil or pyranol-insulated foil-paper capacitors because of continuous-duty rating. The low value of the capacitor results in small starting torque which is about 50 to 100 per cent of the rated torque (Fig. 36.29). Consequently, these motors are used where the required starting torque is low such as air - moving equipment *i.e.* fans, blowers and voltage regulators and also oil burners where quiet operation is particularly desirable.

One unique feature of this type of motor is that it can be easily reversed by an external switch provided its **running and starting windings are identical**. One serves as the running winding and the other as a starting winding for one direction of rotation. For reverse rotation, the one that previously served as a running winding becomes the starting winding while the former starting winding serves as the running winding. As seen from Fig. 36.30 when the switch is in the forward position, winding B serves as running winding and A as starting winding. When switch is in 'reverse' position, winding A becomes the running winding and B the starting winding.

Such reversible motors are often used for operating devices that must be moved back and forth very frequently such as rheostats, induction regulations, furnace controls, valves and arc-welding controls.

### (ii) Two-value capacitor-Run Motor

This motor starts with a high capacitor in series with the starting winding so that the starting torque is high. For running, a lower capacitor is substituted by the centrifugal switch. Both the running and starting windings remain in circuit.

The two values of capacitance can be obtained as follows:

1. by using two capacitors in parallel at the start and then switching out one for low-value run. (Fig. 36.31) or
2. by using a step-up auto-transformer in conjunction with one capacitor so that effective capacitance value is increased for starting purposes.

In Fig. 36.31, *B* is an electrolytic capacitor of high capacity (short duty) and *A* is an oil capacitor of low value (continuous duty). Generally, starting capacitor *B* is 10 to 15 times the running capacitor *A*. At the start, when the centrifugal switch is closed, the two capacitors are put in parallel, so that their combined capacitance is the sum of their individual capacitances. After the motor has reached 75 per cent full-load speed, the switch opens and only capacitor *A* remains in the starting winding circuit. In this way, both optimum starting and running performance is achieved in such motors. If properly designed, such motors have operating characteristics very closely resembling those displayed by two-phase motors. Their performance is characterised by

1. ability to start heavy loads  
 2. extremely quiet operation  
 3. higher efficiency and power factor  
 4. ability to develop 25 per cent overload capacity

Hence, such motors are ideally suited where load requirements are severe as in the case of compressors and fire strokers etc.

The use of an auto-transformer and single oil-type capacitor is illustrated in Fig.36.32. The transformer and capacitor are sealed in a rectangular iron box and mounted on top of the motor. The idea behind using this combination is that a capacitor of value *C* connected to the secondary of a step-up transformer, appears to the primary as though it had a value of  $K^2C$  where *K* is voltage transformation ratio. For example, if actual value of *C* = 4  $\mu$ F and *K* = 6, then low-voltage primary acts as if it had a 144  $\mu$ F (=  $6^2 \times 4$ ) capacitor connected across its terminals. Obviously, effective value of capacitance has increased 36 times. In the 'start' position of the switch, the connection is made to the

Fig. 36.31

Fig.36.32

Auto-transformer

mid-tap of the auto-transformer so that  $K = 2$ . Hence, effective value of capacitance at start is 4 times the running value and is sufficient to give a high starting torque. As the motor speeds up, the centrifugal switch shifts the capacitor from one voltage tap to another so that the voltage transformation ratio changes from higher value at starting to a lower value for running. The capacitor which is actually of the paper-tin-foil construction is immersed in a high grade insulation like wax or mineral oil.

### 36.9. Shaded-pole Single-phase Motor

In such motors, the necessary phase-splitting is produced by induction. These motors have salient poles on the stator and a squirrel-cage type rotor Fig. 36.33 shows a four-pole motor with the field poles connected in series for alternate polarity. One pole of such a motor is shown separately in Fig. 36.34. The laminated pole has a slot cut across the laminations approximately one-third distance from one edge. Around the small part of the pole is placed a short-circuited Cu coil known as *shading coil*. This part of the pole is known as *shaded* part and the other as *unshaded* part. When an alternating current is passed through the exciting (or field) winding

Shaded pole single phase motor

surrounding the whole pole, the axis of the pole shifts from the unshaded part *a* to the shaded part *b*. This shifting of the magnetic axis is, in effect, equivalent to the actual physical movement of the pole. Hence, the rotor starts rotating in the direction of this shift *i.e.* from unshaded part to the shaded part.

Fig. 36.33

Fig. 36.34

Let us now discuss why shifting of the magnetic axis takes place. It is helpful to remember that the shading coil is highly inductive. When the alternating current through exciting coil tends to increase, it induces a current in the shading coil by transformer action in such a direction as to oppose its growth. Hence, flux density decreases in the shaded part when exciting current increases. However, flux density increases in the shaded part when exciting current starts decreasing (it being assumed that exciting current is sinusoidal).

In Fig. 36.35 (a) exciting current is rapidly increasing along *OA* (shown by dots). This will produce an e.m.f. in the shading coil. As shading coil is of low resistance, a large current will be set up in such a direction (according to Lenz's law) as to oppose the rise of exciting current (which is responsible for its production). Hence, the flux mostly shifts to the unshaded part and the magnetic axis lies along the middle of this part *i.e.* along *NC*.

Next, consider the moment when exciting current is near its peak value *i.e.* from point *A* to *B* [Fig. 36.35 (b)]. Here, the change in exciting current is very slow. Hence, practically no voltage and, therefore, no current is induced in the shading coil. The flux produced by exciting current is at its maximum value and is uniformly distributed over the pole face. So the magnetic axis shifts to the centre of the pole *i.e.* along positions *ND*.

Fig. 36.35 (c) represents the condition when the exciting current is rapidly decreasing from *B* to *C*. This again sets up induced current in the shading coil by transformer action. This current will flow in such a direction as to oppose this decrease in exciting current, with the result that the flux is strengthened in the shaded part of the pole. Consequently, the magnetic axis shifts to the middle part of the shaded pole *i.e.* along *NE*.

Fig. 36.35

From the above discussion we find that during the positive half-cycle of the exciting current, a *N*-pole shifts along the pole from the unshaded to the shaded part. During the next negative half-cycle of the exciting current, a *S*-pole trails along. The effect is as if a number of real poles were actually sweeping across the space from left to right.

Shaded pole motors are built commercially in very small sizes, varying approximately from 1/250 h.p. (3W) to 1/6 h.p. (125 W). Although such motors are simple in construction, extremely rugged, reliable and cheap, they suffer from the disadvantages of (i) low starting torque (ii) very little overload capacity and (iii) low efficiency. Efficiencies vary from 5% (for tiny sizes) to 35 (for higher ratings). Because of its low starting torque, the shaded-pole motor is generally used for small fans, toys, instruments, hair dryers, ventilators, circulators and electric clocks. It is also frequently used for such devices as churns, phonograph turntables and advertising displays etc. The direction of rotation of this motor cannot be changed, because it is fixed by the position of copper rings.

Fig. 36.36

A typical torque / speed curve for such a motor is shown in Fig. 36.36.

### 36.10. Repulsion Type Motors

These can be divided into the following four distinct categories :

- 1. Repulsion Motor.** It consists of (a) one stator winding (b) one rotor which is wound like a d.c. armature (c) commutator and (d) a set of brushes, which are short-circuited and remain in contact with the commutator at all times. It operates continuously on the 'repulsion' principle. No short-circuiting mechanism is required for this type.
- 2. Compensated Repulsion Motor.** It is identical with repulsion motor in all respects, except that (a) it carries an additional stator winding, called compensating winding (b) there is another set of two brushes which are placed midway between the usual short-circuited brush set. The compensating winding and this added set are connected in series.
- 3. Repulsion-start Induction-run Motor.** This motor starts as a repulsion motor, but normally runs as an induction motor, with constant speed characteristics. It consists of (a) one stator winding (b) one rotor which is similar to the wire-wound d.c. armature (c) a commutator and (d) a centrifugal mechanism which short-circuits the commutator bars all the way round (with the help of a short-circuiting necklace) when the motor has reached nearly 75 per cent of full speed.
- 4. Repulsion Induction Motor.** It works on the combined principle of repulsion and induction. It consists of (a) stator winding (b) two rotor windings : one squirrel cage and the other usual d.c. winding connected to the commutator and (c) a short-circuited set of two brushes.

Repulsion induction motor

It may be noted that repulsion motors have excellent characteristics, but are expensive and require more attention and maintenance than single-phase motors. Hence, they are being replaced by two-value capacitor motors for nearly all applications.

### 36.11. Repulsion Motor

Constructionally, it consists of the following :

- 1.** Stator winding of the distributed non-salient pole type housed in the slots of a smooth-cored stator (just as in the case of split-phase motors). The stator is generally wound for four, six or eight poles.
- 2.** A rotor (slotted core type) carrying a distributed winding (either lap or wave) which is connected to the commutator. The rotor is identical in construction to the d.c. armature.
- 3.** A commutator, which may be one of the two types : an axial commutator with bars parallel to the shaft or a radial or vertical commutator having radial bars on which brushes press horizontally.
- 4.** Carbon brushes (fitted in brush holders) which ride against the commutator and are used for conducting current through the armature (*i.e.* rotor) winding.

### 36.12. Repulsion Principle

To understand how torque is developed by the repulsion principle, consider Fig. 36.37 which shows a 2-pole salient pole motor with the magnetic axis vertical. For easy understanding, the stator winding has been shown with concentrated salient-pole construction (actually it is of distributed non-salient type). The basic functioning of the machine will be the same with either type of construction. As mentioned before, the armature is of standard d.c. construction with commutator and brushes (which are short-circuited with a low-resistance jumper).

Suppose that the direction of flow of the alternating current in the exciting or field (stator) winding is such that it creates a *N*-pole at the top and a *S*-pole at the bottom. The alternating flux produced by the stator winding will induce e.m.f. in the armature conductors by transformer action. The direction of the induced e.m.f. can be found by using Lenz's law and is as shown in Fig. 36.37 (a). However, the direction of the *induced* currents in the armature conductors will depend on the *positions of the short-circuited brushes*.

Fig. 36.37

If brush axis is colinear with magnetic axis of the main poles, the directions of the induced currents (shown by dots and arrows) will be as indicated in Fig. 36.37 (a)\*. As a result, the armature will become an electromagnet with a *N*-pole on its top, directly under the main *N*-pole and with a *S*-pole at the bottom, directly over the main *S*-pole. Because of this face-to-face positioning of the main and induced magnetic poles, no torque will be developed. The two forces of repulsion on top and bottom act along *Y Y'* in direct opposition to each other.\*\*

If brushes are shifted through 90° to the position shown in Fig. 36.37 (b) so that the brush axis is at right angles to

the magnetic axis of the main poles, the directions of the induced voltages at any time in the respective armature conductors are exactly the same as they were for the brush position of Fig. 36.37 (a). However, with brush positions of Fig. 36.37 (b), the voltages induced in the armature conductors in each path between the brush terminals will neutralize each other, hence there will be no net voltage across brushes to produce armature current. If there is no armature current, obviously, no torque will be developed.

If the brushes are set in position shown in Fig. 36.38 (a) so that the brush axis is neither in line with nor 90° from the magnetic axis *Y Y'* of the main poles, a net voltage\*\*\* will be induced between the brush terminals which will produce armature current. The armature will again act as an elec-

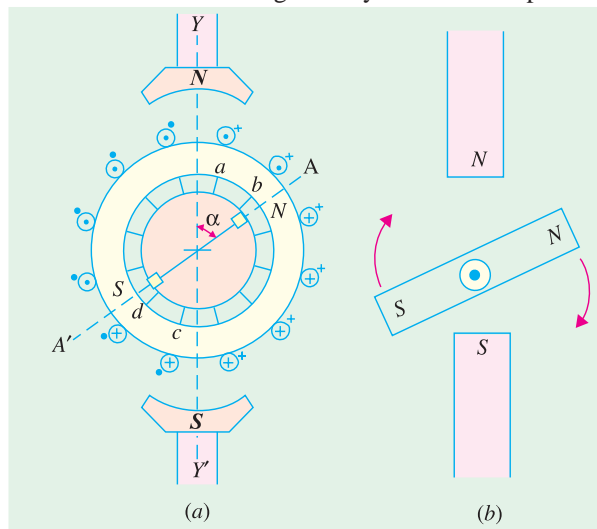

Fig. 36.38

\* It should be noted that during the next half-cycle of the supply current, the directions of the respective voltages will be in the opposite directions.

\*\* Alternatively, the absence of the torque may be explained by arguing that the torques developed in the four quadrants neutralize each other.

\*\*\* It will be seen from Fig. 36.38 (a) that the induced voltages in conductors *a* and *b* oppose the voltages in other conductors lying above brush-axis. Similarly, induced voltages in conductors *c* and *d* oppose the voltages in other conductors, lying below the brush-axis. Yet the net voltage across brush terminals will be sufficient to produce current which will make the armature a powerful magnet.

tromagnet and develop its own *N*- and *S*-poles which, in this case, will not directly face the respective main poles. As shown in Fig. 36.38 (a), the armature poles lie along *AA'* making an angle of  $\alpha$  with *YY*.

Hence, rotor *N*-pole will be repelled by the main *N*-pole and the rotor *S*-pole will, similarly, be repelled by the main *S*-pole. Consequently, the rotor will rotate in clockwise direction [Fig.36.38 (b)]. Since the forces are those of *repulsion*, it is appropriate to call the motor as repulsion motor.

It should be noted that if the brushes are shifted counter-clockwise from *YY'*, rotation will also be counter-clockwise. Obviously, direction of rotation of the motor is determined by the position of brushes with respect to the main magnetic axis.

It is worth noting that the value of starting torque developed by such a motor will depend on the *amount* of brush-shift whereas direction of rotation will depend on the *direction* of shift [Fig. 36.39 (a)]. Maximum starting torque is developed at some position where brush axis makes, an angle lying between  $0^\circ$  and  $45^\circ$  with the magnetic axis of main poles. Motor speed can also be controlled by means of brush shift. Variation of starting torque of a repulsion motor with brush-shift is shown in Fig. 36.39 (b).

Repulsion motor

A straight repulsion type motor has high starting torque (about 350 per cent) and moderate starting current (about 3 to 4 times full-load value).

Principal shortcomings of such a motor are :

1. speed varies with changing load, becoming dangerously high at no load.
2. low power factor, except at high speeds.
3. tendency to spark at brushes.

### 36.13. Compensated Repulsion Motor

It is a modified form of the straight repulsion motor discussed above. It has an additional stator winding, called compensating winding whose purpose is (i) to improve power-factor and (ii) to provide better speed regulation. This winding is much smaller than the stator winding and is usually wound in the inner slots of each main pole and is connected in series with the armature (Fig. 36.40) through an additional set of brushes placed mid-way between the usual short-circuited brushes.

Fig. 36. 39

Fig. 36. 40

### 36.14. Repulsion-start Induction-Run Motor

As mentioned earlier, this motor starts as an ordinary repulsion motor, but after it reaches about 75 per cent of its full speed, centrifugal short-circuiting device short-circuits its commutator. From

then on, it runs as an induction motor, with a short-circuited squirrel-cage rotor. After the commutator is short-circuited, brushes do not carry any current, hence they may also be lifted from the commutator, in order to avoid unnecessary wear and tear and friction losses.

Repulsion-start motors are of two different designs :

1. Brush-lifting type in which the brushes are automatically lifted from the commutator when it is short-circuited. These motors generally employ radial form of commutator and are built both in small and large sizes.
2. Brush-riding type in which brushes ride on the commutator at all times. These motors use axial form of commutator and are always built in small sizes.

The starting torque of such a motor is in excess of 350 per cent with moderate starting current. It is particularly useful where starting period is of comparatively long duration, because of high inertia loads. Applications of such motors include machine tools, commercial refrigerators, compressors, pumps, hoists, floor-polishing and grinding devices etc.

### 36.15. Repulsion Induction Motor

In the field of repulsion motor, this type is becoming very popular, because of its good all-round characteristics which are comparable to those of a compound d.c. motor. It is particularly suitable for those applications where the load can be removed entirely by de-clutching or by a loose pulley.

This motor is a combination of the repulsion and induction types and is sometimes referred to as *squirrel-cage repulsion motor*. It possesses the desirable characteristics of a repulsion motor and the constant-speed characteristics of an induction motor.

It has the usual stator winding as in all repulsion motors. But there are two separate and independent windings in the rotor (Fig. 36.41).

- (i) a squirrel-cage winding and
- (ii) commutated winding similar to that of a d.c. armature.

Both these windings function during the *entire period* of operation of the motor. The commutated winding lies in the outer slots while squirrel-cage winding is located in the inner slots\*. At start, the commutated winding supplies most of the torque, the squirrel-cage winding being practically inactive because of its high reactance. When the rotor accelerates, the squirrel-cage winding takes up a larger portion of the load.

The brushes are short-circuited and ride on the commutator continuously. One of the advantages of this motor is that it requires no centrifugal short-circuiting mechanism. Sometimes such motors are also made with compensating winding for improving the power factor.

As shown in Fig. 36.42, its starting torque is high, being in excess of 300 per cent. Moreover, it has a fairly constant speed regulation. Its field of application includes house-hold refrigerators, garage air pumps, petrol pumps, compressors, machine tools, mixing machines, lifts and hoists etc.

Brushless d.c. seromotor

\* Hence, commutated winding has low resistance whereas the squirrel-cage winding has inherently a high reactance.

Fig. 36.41

Fig. 36.42

These motors can be reversed by the usual brush-shifting arrangement.

### 36.16. A.C. Series Motors

If an ordinary d.c. series motor were connected to an a.c. supply, it will rotate and exert unidirectional torque\* because the current flowing both in the armature and field reverses at the same time. But the performance of such a motor will not be satisfactory for the following reasons :

1. the alternating flux would cause excessive eddy current loss in the yoke and field cores which will become extremely heated.
2. vicious sparking will occur at brushes because of the huge voltage and current induced in the short-circuited armature coils during their commutation period.
3. power factor is low because of high inductance of the field and armature circuits.

Induction type AC servo motor and control box

However, by proper modification of design and other refinements, a satisfactory single-phase motor has been produced.

The eddy current loss has been reduced by laminating the entire iron structure of the field cores and yoke.

Power factor improvement is possible only by reducing the magnitudes of the reactances of the field and armature windings. Field reactance is reduced by reducing the number of turns on the field windings. For a given current, it will reduce the field m.m.f. which will result in reduced air-gap flux. This will tend to increase the speed but reduce motor torque. To obtain the same torque, it will now be necessary to increase the number of armature turns proportionately. This will, however, result in increased inductive reactance of the armature, so that the overall reactance of the motor will not be

\* However, torque developed is not of constant magnitude (as in d.c. series motors) but pulsates between zero and maximum value each half-cycle.

significantly decreased. Increased armature m.m.f. can be neutralized effectively by using a compensating winding. In conductively-compensated motors, the compensating winding is connected in series with the armature [Fig. 36.43 (a)] whereas in inductively-compensated motors, the compensating winding is short-circuited and has no interconnection with the motor circuit [Fig. 36.43 (b)]. The compensating winding acts as a short-circuited secondary of a transformer, for which the armature winding acts as a primary. The current in the compensating winding will be proportional to the armature current and  $180^\circ$  out of phase with it.

Fig. 36.43

Generally, all d.c. series motors are 'provided' with commutating poles for improving commutation (as in d.c. motors). But commutating poles alone will not produce satisfactory commutation, unless something is done to neutralize the huge voltage induced in the short-circuited armature coil by transformer action (this voltage is not there in d.c. series motor). It should be noted that in an a.c. series motor, the flux produced by the field winding is alternating and it induces voltage (by transformer action) in the short-circuited armature coil during its commutating period. The field winding, associated with the armature coil undergoing commutation, acts as primary and the armature coil during its commutating period acts as a short-circuited secondary. This transformer action produces heavy current in the armature coil as it passes through its commutating period and results in vicious sparking, unless the transformer voltage is neutralized. One method, which is often used for large motors, consists of shunting the winding of each commutating pole with a non-inductive resistance, as shown in Fig. 36.44 (a).

Fig. 36.44

Fig. 36.44. (b) shows the vector diagram of a shunted commutator pole. The current  $I_c$  through the commutating pole (which lags the total motor current) can be resolved into two rectangular components  $I_d$  and  $I_q$  as shown.  $I_d$  produces a flux which is in phase with total motor current  $I$  whereas flux produced by  $I_q$  lags  $I$  by  $90^\circ$ . By proper adjustment of shunt resistance (and hence  $I_s$ ), the speed voltage generated in a short-circuited coil by the cutting of the  $90^\circ$  lagging component of the commutating pole flux may be made to neutralize the voltage induced by transformer action.

### 36.17. Universal Motor

A universal motor is defined as a motor which may be operated either on direct or single-phase

a.c. supply at approximately the same speed and output.

In fact, it is a smaller version (5 to 150 W) of the a.c. series motor described in Art. 36.16. Being a series-wound motor, it has high starting torque and a variable speed characteristic. It runs at dangerously high speed on no-load. That is why such motors are usually built into the device they drive.

Generally, universal motors are manufactured in two types:

1. **concentrated-pole, non-compensated type** (low power rating)
2. **distributed-field compensated type** (high power rating)

The non-compensated motor has two salient poles and is just like a 2-pole series d.c. motor except that whole of its magnetic path is laminated (Fig. 36.45). The laminated stator is necessary because the flux is alternating when motor is operated from a.c. supply. The armature is of wound type and similar to that of a small d.c. motor. It consists essentially of a laminated core having either straight or skewed slots and a commutator to which the leads of the armature winding are connected.

Universal motor.

Fig. 36.45

The distributed-field compensated type motor has a stator core similar to that of a split-phase motor and a wound armature similar to that of a small d.c. motor. The compensating winding is used to reduce the reactance voltage present in the armature when motor runs on a.c. supply. This voltage is caused by the alternating flux by transformer action (Art. 36.16).

In a 2-pole non-compensated motor, the voltage induced by transformer action in a coil during its commutation period is not sufficient to cause any serious commutation trouble. Moreover, high-resistance brushes are used to aid commutation.

Fig. 36.46

Fig.36.47

**(a) Operation.** As explained in Art. 36.16, such motors develop unidirectional torque, regardless of whether they operate on d.c. or a.c. supply. The production of unidirectional torque, when the motor runs on a.c. supply can be easily understood from Fig. 36.46. The motor works on the same principle as a d.c. motor *i.e.* force between the main pole flux and the current-carrying armature conductors. This is true regardless of whether the current is alternating or direct (Fig. 36.47).

**(b) Speed/Load Characteristic.** The speed of a universal motor varies just like that of a d.c. series motor *i.e.* low at full-load and high on no-load (about 20,000 r.p.m. in some cases). In fact, on no-load the speed is limited only by its own friction and windage load. Fig. 36.48 shows typical torque characteristics of a universal motor both for d.c. and a.c. supply. Usually, gear trains are used to reduce the actual load speeds to proper values.

**(c) Applications.** Universal motors are used in vacuum cleaners where actual motor speed is the load speed. Other applications where motor speed is reduced by a gear train are : drink and food mixers, portable drills and domestic sewing machine etc.

**(d) Reversal of Rotation.** The concentrated-pole (or salient-pole) type universal motor may be reversed by reversing the flow of current through either the armature or field windings. The usual method is to interchange the leads on the brush holders (Fig.36.49).

The distributed-field compensated type universal motor may be reversed by interchanging either the armature or field leads and shifting the brushes against the direction in which the motor will rotate. The extent of brush shift usually amounts to several commutator bars.

Fig. 36.48

Fig.36.49

### 36.18. Speed Control of Universal Motors

The following methods are usually employed for speed-control purposes :

**(i) Resistance Method.** As shown in Fig. 36.50, the motor speed is controlled by connecting a variable resistance  $R$  in series with the motor. This method is employed for motors used in sewing machines. The amount of resistance in the circuit is changed by means of a foot-pedal.

**(ii) Tapping-field Method.** In this method, a field pole is tapped at various points and speed is controlled by varying the field strength (Fig. 36.51). For this purpose, either of the following two arrangements may be used :

- (a)** The field pole is wound in various sections with different sizes of wire and taps are brought out from each section.
- (b)** Nichrome resistance wire is wound over one field pole and taps are brought out from this wire.

(iii) **Centrifugal Mechanism.** Universal motors, particularly those used for home food and drink mixers, have a number of speeds. Selection is made by a centrifugal device located inside the motor and connected, as shown in Fig. 36.52. The switch is adjustable by means of an external lever. If the motor speed rises above that set by the lever, the centrifugal device opens two contacts and inserts resistance  $R$  in the circuit, which causes the motor speed to decrease. When motor runs slow, the two contacts close and short-circuit the resistance, so that the motor speed rises. This process is repeated so rapidly that variations in speed are not noticeable.

Universal motor used for home food and drink mixers

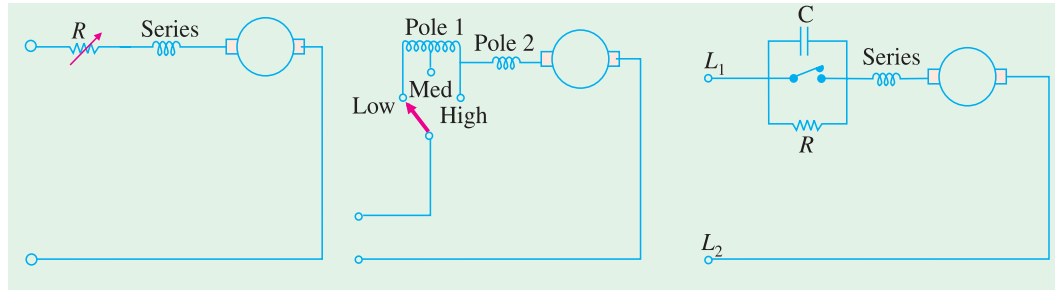

Fig. 36.50

Fig. 36.51

Fig. 36.52

The resistance  $R$  is connected across the governor points as shown in Fig. 36.52. A capacitor  $C$  is used across the contact points in order to reduce sparking produced due to the opening and closing of these points. Moreover, it prevents the pitting of contacts.

**Example 36.4.** A 250-W, single-phase, 50-Hz, 220-V universal motor runs at 2000 rpm and takes 1.0 A when supplied from a 220-V dc. supply. If the motor is connected to 220-V ac supply and takes 1.0 A (r.m.s), calculate the speed, torque and power factor. Assume  $R_a = 20 \Omega$  and  $L_a = 0.4$  H.

**Solution. DC Operation :**  $E_{b,dc} = V - I_a R_a$   
 $= 220 - 20 \times 1 = 200$  V

**AC Operation**

$X_a = 2 \pi \times 50 \times 0.4 = 125.7 \Omega$ .

As seen from Fig.36.53.

$V^2 = (E_{b,ac} + I_a R_a)^2 + (I_a \times X_a)^2$

$\therefore E_{b,ac} = -I_a R_a + \sqrt{V^2 - (I_a X_a)^2}$

$= -1 \times 20 + \sqrt{220^2 - (125.7 \times 1)^2} = 160.5$  V

Fig. 36.53

Since armature current is the same for both dc and ac excitations, hence

$\frac{E_{b,dc}}{E_{b,ac}} = \frac{N_{dc}}{N_{ac}} ; \quad \therefore N_{ac} = 2000 \times \frac{160.5}{200} = 1605$  rpm

$\cos \phi = AB/OB = (E_{b,ac} + I_a R_a) / V = (160.5 + 20) / 220 = 0.82$  lag

$$P_{mech} = E_{b.ac} \cdot I_a = 160.5 \times 1 = 160.5 \text{ W}$$

$$T = 9.55 \times 160.5/1605 = \mathbf{0.955 \text{ N-m}}$$

**Example 36.5.** A universal series motor has resistance of  $30 \Omega$  and an inductance of  $0.5 \text{ H}$ . When connected to a  $250 \text{ V d.c.}$  supply and loaded to take  $0.8 \text{ A}$ , it runs at  $2000 \text{ r.p.m.}$  Estimate its speed and power factor, when connected to a  $250\text{-V, } 50\text{-Hz a.c.}$  supply and loaded to take the same current. (Elect. Machine, A.M.I.E. Sec. B, 1992)

**Solution. A.C. Operation**

$$X_a = 2 \pi \times 50 \times 0.5 = 157 \Omega,$$

$$R_a = 30 \Omega$$

$$I_a R_a = 0.8 \times 30 = 24 \Omega$$

$$I_a X_a = 0.8 \times 157 = 125.6 \text{ V}$$

The phasor diagram is shown in Fig. 36.54 (b)

$$V^2 = (E_{b.ac} + I_a R_a)^2 + (I_a X_a)^2$$

$$250^2 = (E_{b.ac} + 24)^2 + 125.6^2$$

$$\therefore E_{b.ac} = 192.6$$

**DC Operation**

$$E_{b.dc} = 250 - 0.8 \times 30 = 226 \text{ V}$$

Now,  $\frac{E_{b.ac}}{E_{b.dc}} = \frac{N_{ac}}{N_{dc}}$  or  $\frac{192.12}{226} = \frac{N_{ac}}{2000}$  ;

$$N_{ac} = 1700 \text{ rpm}$$

$$\cos \phi = (E_{b.ac} + I_a R_a)/V = 236.12/250 = \mathbf{0.864 \text{ lag}}$$

Fig. 36.54

**36.19. Unexcited Single-phase Synchronous Motors**

These motors

1. operate from a single-phase a.c. supply
2. run at a constant speed – the synchronous speed of the revolving flux
3. need no d.c. excitation for their rotors (that is why they are called *unexcited*)
4. are self-starting.

These are of two types (a) reluctance motor and (b) hysteresis motor.

**36.20. Reluctance Motor**

It has either the conventional split-phase stator and a centrifugal switch for cutting out the auxiliary winding (split-phase type reluctance motor) or a stator similar to that of a permanent-split capacitor-run motor (capacitor-type reluctance motor). The stator produces the revolving field.

The squirrel-cage rotor is of unsymmetrical magnetic construction. This type of unsymmetrical construction can be achieved by removing some of the teeth of a symmetrical squirrel-cage rotor punching. For example, in a 48-teeth, four-pole rotor following teeth may be cut away :

- 1, 2, 3, 4, 5, 6–13, 14, 15, 16, 17, 18–25, 26, 27, 28, 29, 30–37, 38, 39, 40, 41, 42.

This would leave four projecting or salient poles (Fig. 36.55) consisting of the following sets of teeth : 7–12; 19–24; 31–36 and 43–48. In this way, the rotor offers variable magnetic reluctance to the stator flux, the reluctance varying with the position of the rotor.

Fig. 36.55

### Working

For understanding the working of such a motor one basic fact must be kept in mind. And it is that when a piece of magnetic material is located in a magnetic field, a force acts on the material, tending to bring it into the most dense portion of the field. The force tends to align the specimen of material in such a way that the reluctance of the magnetic path that lies through the material will be minimum.

When the stator winding is energised, the revolving magnetic field exerts reluctance torque on the unsymmetrical rotor tending to align the salient pole axis of the rotor with the axis of the revolving magnetic field (because in this position, the reluctance of the magnetic path is minimum). If the reluctance torque is sufficient to start the motor and its load, the rotor will pull into step with the revolving field and continue to run at the speed of the revolving field.\*

However, even though the rotor revolves synchronously, its poles lag behind the stator poles by a certain angle known as torque angle, (something similar to that in a synchronous motor). The reluctance torque increases with increase in torque angle, attaining maximum value when  $\alpha = 45^\circ$ . If  $\alpha$  increases beyond  $45^\circ$ , the rotor falls out of synchronism. The average value of the reluctance torque is given by  $T = K (V/f)^2 \sin 2\delta$  where  $K$  is a motor constant.

It may be noted that the amount of load which a reluctance motor could carry at its *constant speed* would only be a fraction of the load that the motor could normally carry when functioning as an induction motor. If the load is increased beyond a value under which the reluctance torque cannot maintain synchronous speed, the rotor drops out of step with the field. The speed, then, drops to some value at which the slip is sufficient to develop necessary torque to drive the load by induction-motor action.

The constant-speed characteristic of a reluctance motor makes it very suitable for such applications as signalling devices, recording instruments, many kinds of timers and phonographs etc.

### 36.21. Hysteresis Motor

The operation of this motor depends on the presence of a *continuously-revolving* magnetic flux. Hence, for the split-phase operation, its stator has two windings which remain connected to the single-phase supply continuously both at starting as well as during the running of the motor. Usually, shaded-pole principle is employed for this purpose giving shaded-pole hysteresis motor. Alternatively, stator winding of the type used in capacitor-type motor may be used giving capacitor-type shaded-pole motor. Obviously, in either type, no centrifugal device is used.

The rotor is a smooth chrome-steel cylinder\*\* having

\* Actually, the motor starts as an induction motor and after it has reached its maximum speed as an induction motor, the reluctance torque pulls its rotor into step with the revolving field so that the motor now runs as a synchronous motor by virtue of its saliency.

\*\* Rotors of ceramic permanent magnet material are used whose resistivity approaches that of an insulator. Consequently, it is impossible to set up eddy currents in such a rotor. Hence, there is no eddy current loss but only hysteresis loss.

high retentivity so that the hysteresis loss is high. It has no winding. Because of high retentivity of the rotor material, it is very difficult to change the magnetic polarities once they are induced in the rotor by the revolving flux. The rotor revolves synchronously because the rotor poles magnetically lock up with the revolving stator poles of opposite polarity. However, the rotor poles always lag behind the stator poles by an angle  $\alpha$ . Mechanical power developed by rotor is given by  $P_m = P_h \left( \frac{1-s}{s} \right)$  where  $P_h$  is hysteresis loss in rotor. Also  $T_h = 9.55 P_m / N_s$ . It is seen that hysteresis torque depends solely on the area of rotor's hysteresis loop.

The fact that the rotor has no teeth or winding of any sort, results in making the motor extremely quiet in operation and free from mechanical and magnetic vibrations. This makes the motor particularly useful for driving tape-decks, tape-decks, turn-tables and other precision audio equipment. Since, commercial motors usually have two poles, they run at 3,000 r.p.m. at 50-Hz single-phase supply. In order to adopt such a motor for driving an electric clock and other indicating devices, gear train is connected to the motor shaft for reducing the load speed. The unit accelerates rapidly, changing from rest to full speed almost instantaneously. It must do so because it cannot accelerate gradually as an ordinary motor it is either operating at synchronous speed or not at all.

Fig. 36.56

Some unique features of a hysteresis motor are as under :

- (i) since its hysteresis torque remains practically constant from locked rotor to synchronous speed, a hysteresis motor is able to synchronise any load it can accelerate—something no other motor does.
- (ii) due to its smooth rotor, the motor operates quietly and does not suffer from magnetic pulsations caused by slots/salient-poles that are present in the rotors of other motors.

In Fig. 36.56. is shown a two-pole shaded-pole type hysteresis motor used for driving ordinary household electric clocks. The rotor is a thin metal cylinder and the shaft drives a gear train.

**Example 36.6.** A 8-kW, 4-pole, 220-V, 50-Hz reluctance motor has a torque angle of  $30^\circ$  when operating under rated load conditions. Calculate (i) load torque (ii) torque angle if the voltage drops to 205 V and (iii) will the rotor pulled out of synchronism ?

**Solution.** (i)  $N_s = 120 \times 50/4 = 1500$  rpm;  $T_{sh} = 9.55 \times \text{output}/N = 9.55 \times 8000/1500 = 51N\text{-m}$

(ii) With the same load torque and constant frequency,

$$V_1 \sin 2\alpha_1 = V_2^2 \sin 2\alpha_2$$

$$\therefore 220^2 \times \sin (2 \times 30^\circ) = 205^2 \times \sin 2\alpha; \quad \therefore \alpha = 42.9^\circ$$

(iii) since the new load angle is less than  $45^\circ$ , the rotor will not pull out of synchronous.

### Tutorial Problems-36.2.

1. A 230-V, 50-Hz, 4-pole, class-A, single-phase induction motor has the following parameters at an operating temperature  $63^\circ\text{C}$  :

$$r_{1m} = 2.51 \text{ ohms}, r_2' = 7.81 \text{ ohm}, X_m = 150.88 \text{ ohm}, X_{im} = 4.62 \text{ ohm}, X_2' = 4.62 \text{ ohms}$$

Determine stator main winding current and power factor when the motor is running at a slip of 0.05 at the specified temperature of  $63^\circ\text{C}$ .

[3.74  $\angle 48.24^\circ$ , 0.666] (AMIE Sec. B Elect. Machines (E-B) Summer 1991)

2. A fractional horse-power universal motor has armature circuit resistance of 20 ohm and inductance of 0.4 H. On being connected to a 220-V d.c. supply, it draws 1.0 A from the mains and runs at 2000 r.p.m. Estimate the speed and power factor of the motor, when connected to a 230-V, 50-Hz supply drawing the same armature current. Draw relevant phasor diagram.  
 [1726 rpm, 0.84] (AMIE Sec. B Elect. Machines 1991)
3. A universal series motor, when operating on 220 V d.c. draws 10 A and runs at 1400 r.p.m. Find the new speed and power factor, when connected to 220 V, 25 Hz supply, the motor current remaining the same. The motor has total resistance of 1 ohm and total inductance of 0.1 H.  
 [961 rpm; 0.7] (AMIE Sec. B Elect. Machines 1990)

QUESTIONS AND ANSWERS ON SINGLE-PHASE MOTORS

**Q.1. How would you reverse the direction of rotation of a capacitor start-induction-run motor ?**

**Ans.** By reversing either the running or starting-winding leads where they are connected to the lines. Both must not be reversed.

Fig. 36.57

**Q.2. In which direction does a shaded-pole motor run ?**

**Ans.** It runs from the unshaded to the shaded pole (Fig.36.57)

**Q.3. Can such a motor be reversed ?**

**Ans.** Normally, such motors are not reversible because that would involve mechanical dismantling and re-assembly. However, special motors are made having two rotors on a common shaft, each having one stator assembly for rotation in opposite direction.

**Q.4. What is a universal motor ?**

**Ans.** It is built like a series d.c. motor with the difference that both its stator and armature are laminated. They can be used either on d.c. or a.c. supply although the speed and power are greater on direct current. They cannot be satisfactorily made to run at less than about 2000 r.p.m.

**Q.5. How can a universal motor be reversed ?**

**Ans.** By reversing either the field leads or armature leads but not both.

Fig. 36.58

**Q.6. How can we reverse the direction of rotation of repulsion, repulsion-induction and repulsion-induction and repulsion- start-induction-run motors ?**

**Ans.** By shifting the brush positions by about 15° electrical.

**Q.7. How can we reverse the rotation of a 1-phase, split-phase motor ?**

**Ans.** By reversing the leads to either the running or starter winding (Fig. 36.58) but not both.

**Q.8. What could be the reasons if a repulsion-induction motor fails to start ?**

**Ans.** Any one of the following :

1. no supply voltage
2. low voltage
3. excessive overload
4. the bearing lining may be stuck or 'frozen' to the shaft
5. armature may be rubbing
6. brush yoke may be incorrectly located
7. brush spacing may be wrong.

**Q.9. What could be the reasons if a split-phase motor fails to start and hums loudly ?**

**Ans.** It could be due to the starting winding being open or grounded or burnt out.

**Q.10. What could be the reasons if a split-phase motor runs too slow ?**

**Ans.** Any one of the following factors could be responsible :

1. wrong supply voltage and frequency
2. overload
3. grounded starting and running windings
4. short-circuited or open winding in field circuit.

### OBJECTIVE TESTS – 36

1. The starting winding of a single-phase motor is placed in the
  - (a) rotor
  - (b) stator
  - (c) armature
  - (d) field.
2. One of the characteristics of a single-phase motor is that it
  - (a) is self-starting
  - (b) is not self-starting
  - (c) requires only one winding
  - (d) can rotate in one direction only.
3. After the starting winding of a single-phase induction motor is disconnected from supply, it continues to run only on .....winding.
  - (a) rotor
  - (b) compensating
  - (c) field
  - (d) running
4. If starting winding of a single-phase induction motor is left in the circuit, it will
  - (a) draw excessive current and overheat
  - (b) run slower
  - (c) run faster
  - (d) spark at light loads.
5. The direction of rotation of a single-phase motor can be reversed by
  - (a) reversing connections of both windings
  - (b) reversing connections of starting winding
  - (c) using a reversing switch
  - (d) reversing supply connections.
6. If a single-phase induction motor runs slower than normal, the more likely defect is
  - (a) improper fuses
  - (b) shorted running winding
  - (c) open starting winding
  - (d) worn bearings.
7. The capacitor in a capacitor-start induction-run ac motor is connected in series with ..... winding.
  - (a) starting
  - (b) running
  - (c) squirrel-cage
  - (d) compensating
8. A permanent-split single-phase capacitor motor does not have
  - (a) centrifugal switch
  - (b) starting winding
  - (c) squirrel-cage rotor
  - (d) high power factor.
9. The starting torque of a capacitor-start induction-run motor is directly related to the angle  $\alpha$  between its two winding currents by the relation
  - (a)  $\cos \alpha$
  - (b)  $\sin \alpha$
  - (c)  $\tan \alpha$
  - (d)  $\sin \alpha/2$ .
10. In a two-value capacitor motor, the capacitor used for running purposes is a/an
  - (a) dry-type ac electrolytic capacitor
  - (b) paper-spaced oil-filled type
  - (c) air-capacitor
  - (d) ceramic type.
11. If the centrifugal switch of a two-value capacitor motor using two capacitors fails to open, then
  - (a) electrolytic capacitor will, in all probability, suffer breakdown
  - (b) motor will not carry the load
  - (c) motor will draw excessively high current
  - (d) motor will not come upto the rated speed.
12. Each of the following statements regarding a shaded-pole motor is true **except**
  - (a) its direction of rotation is from un-shaded to shaded portion of the poles
  - (b) it has very poor efficiency
  - (c) it has very poor p.f.
  - (d) it has high starting torque.
13. Compensating winding is employed in an ac series motor in order to

- (a) compensate for decrease in field flux  
 (b) increase the total torque  
 (c) reduce the sparking at brushes  
 (d) reduce effects of armature reaction.
14. A universal motor is one which  
 (a) is available universally  
 (b) can be marketed internationally  
 (c) can be operated either on dc or ac supply  
 (d) runs at dangerously high speed on no-load.
15. In a single-phase series motor the main purpose of inductively-wound compensating winding is to reduce the  
 (a) reactance emf of commutation  
 (b) rotational emf of commutation  
 (c) transformer emf of commutation  
 (d) none of the above.  
**(Power App.-II, Delhi Univ. Jan. 1987)**
16. A repulsion motor is equipped with  
 (a) a commutator (b) slip-rings  
 (c) a repeller  
 (d) neither (a) nor (b).
17. A repulsion-start induction-run single-phase motor runs as an induction motor only when  
 (a) brushes are shifted to neutral plane  
 (b) short-circuiter is disconnected  
 (c) commutator segments are short-circuited  
 (d) stator winding is reversed.
18. If a dc series motor is operated on ac supply, it will  
 (a) have poor efficiency  
 (b) have poor power factor  
 (c) spark excessively  
 (d) all of the above  
 (e) none of the above.
19. An outstanding feature of a universal motor is its  
 (a) best performance at 50 Hz supply  
 (b) slow speed at all loads  
 (c) excellent performance on dc. supply  
 (d) highest output kW/kg ratio.
20. The direction of rotation of a hysteresis motor is determined by the  
 (a) retentivity of the rotor material  
 (b) amount of hysteresis loss
